Trachea.—The trachea, or windpipe, is the tube that connects the larynx and the bronchi (*see* fig. 4); it is from 4 to 4½ in. long and lies partly in the neck and partly in the thorax. It begins where the larynx ends, at the lower border of the sixth cervical vertebra (*see* fig. 1), and divides into its two bronchi opposite the fifth thoracic vertebra. The tube is kept open by rings of cartilage, shaped like horseshoes and embedded in an external fibroelastic membrane. Behind, where the trachea rests upon the gullet, there is a layer of smooth muscle that can draw the open ends of the rings together and so diminish the calibre of the tube.

Inside there is plentiful submucous tissue containing submucous glands and much lymphoid tissue. The whole is lined internally by columnar ciliated epithelium. These cilia form one segment of a continuous field of upward stroking lashes that carry mucus and inspired material from the lungs to the larynx. At this upper level it can be coughed up.

The cervical part of the tube is not much more than an inch in length, but it can be lengthened by throwing back the head. This is the region in which tracheotomy is performed. At the bifurcation of the trachea the lowest cartilage forms a carina, or keel. In birds the bifurcation is converted into a vocal organ, the syrinx, consisting of vibrating membranes controlled by special muscles. In man, the topographic relations, at this level, are of special importance (*see* fig. 4). If the aorta is pathologically enlarged it may compress the esophagus, causing difficulty in swallowing; or press against the left bronchus, causing difficulty in breathing; or put traction upon the left recurrent laryngeal nerve where it curves around the arch of the aorta, thus affecting the voice.

Below the bifurcation right and left primary bronchi diverge to enter the hilum of the lung. Since the right bronchus more nearly continues the direction of the trachea than the left, foreign bodies swallowed inadvertently by children fall more commonly into the right than into the left lung.

As each primary bronchus enters the lungs it is accompanied by a large pulmonary artery, carrying venous blood to the lung, and a large pulmonary vein conveying oxygenated blood to the heart (*see* fig. 5). In addition there are small bronchiai arteries, lymphatics and nerves.

Lungs.—These are the organs that are formed when right and left bronchial buds of the embryo push out into that portion of the body cavity that later becomes the pleural cavity (*see* COELOM AND SEROUS MEMBRANES). Each lung, therefore, represents the total branching of the primary bronchus plus its supporting tissue, its associated arterial and venous trees and the layer of pleura that surrounds it. Medially it is attached by a reflection of the pleura to the mediastinum, the vertical wall that divides the chest into right and left compartments.

Grossly, each lung is a somewhat conical organ having an apex, which extends into the neck; a base, which rests upon the diaphragm; and other surfaces that are costal and mediastinal. Superficially the right lung is cleft by horizontal and oblique fissures into three lobes; the left lung is cleft into two lobes. This asymmetry is characteristic of most mammals. Equally significant divisions are the bronchopulmonary segments, first recognized as such in 1932. These are polyhedral wedges of tissue separated from each other by veins and thin connective tissue membranes. They represent the zones of distribution of the larger secondary bronchi. On the right side ten such segments have been recognized. On the left the number is restricted to nine, since apical

and posterior segmental bronchi have developed into a single shrublike unit. Although segments are not demarcated by surface fissures they are nevertheless surgical units that can be excised individually, thus making possible the preservation of adjacent healthy tissue that formerly was sacrificed when surgeons were compelled to remove entire lobes in order to remove small lesions.

Commonly, three techniques are available for determining the site of tumours or other lesions in lobes and segments: (1) X-rays of the chest; (2) direct examination of the orifices of the segmental bronchi by means of a bronchoscope lowered into the trachea; and (3) X-rays of the bronchial tree (bronchograms) made after the tree has been filled with a radiopaque fluid.

Bronchial Divisions.—Each of the segmental bronchi divide more or less dichotomously until there are from 20 to 25 generations of branches ending in the terminal bronchioles. The first ten generations are widely spaced divisions and occupy two-thirds to three-fourths of the way to the periphery. These are secondary bronchi, lined by ciliated, pseudostratified epithelium. In their walls are cartilage plates, to keep the air passages open; mucous glands to moisten the ducts; and a mesh of smooth muscle fibres to regulate the calibre of the tubes. These tissues are supplied by bronchial arteries of aortic origin, and by nerves, and are drained by lymphatic vessels and veins. The remaining 10 to 15 generations are bronchioles. These branches have no cartilages, are more closely spaced and have a fairly uniform diameter (3–1 mm.). They end in terminal bronchioles, which give rise to the respiratory portions of the tree.

Finer Structure of Lung.—The terminal bronchioles are small tubes, 0.6 to 0.7 mm. in diameter. They are lined by ciliated columnar epithelium and completely invested by smooth muscle. Spasms of these muscles, as in asthma, can shut off the passage of air. Each of these short tubes gives rise to several generations of respiratory bronchioles (*see* fig. 6), so named because they contain scattered alveoli. Each of these bronchioles gives rise to from 2 to 11 alveolar ducts, and each of these to 5 or 6 alveolar sacs lined by polyhedral alveoli. It has been estimated that there are from 300,000,000 to 400,000,000 alveoli in the lung. These are the functional units (*see* RESPIRATION). Each is about 0.2 mm. in diameter and is lined by an extremely thin epithelial membrane, outside which is a rich capillary plexus. As seen under the electron microscope, adherent alveolar and capillary walls measure only $\frac{1}{2500}$ mm. in thickness. It was the first sight of blood corpuscles circulating through these capillaries in 1661 that led Malpighi to exclaim, "I see with my own eyes a certain great thing" (Sir Michael Foster, *Lectures on the History of Physiology*, p. 96, Cambridge University Press, 1901).

According to W. S. Miller, all the branches of an alveolar duct form a primary lobule. Other investigators start with the respiratory bronchiole. The branches of a terminal bronchus form an acinus. Groups of these constitute a secondary lobule. The latter can be identified on the surface of the lung as one of many irregular polygons marked out by pigment and measuring from 1 to $2\frac{1}{2}$ cm. in diameter. So far, the finer structure of the lung has been presented as a pattern of arborization. However, it should be realized that these peripheral respiratory units become so crowded together that the lung appears in microscopic sections as a meshwork of thin walls separating air spaces. In the 1960s the development of a new technique made it possible to disengage the polygons and restore the treelike form, thus permitting direct examination of alveolar sacs in diseased lungs.

Development of Lungs.—The rudiment of the tracheobronchial tree appears as early as the 25th day of intra-uterine life in the form of a laryngeotracheal groove on the ventral side of the tubular foregut just below the pharynx. A day or so later, two epithelial lung buds push out from the lower end of this groove, indenting the pleural cavities. These are the primitive lung sacs or primary bronchi. This period is a critical one, for occasionally one lung fails to appear. In rats, this condition has been produced experimentally by feeding the mother a diet deficient in vitamin A.

By the 31st day each bronchus has developed secondary buds, which become the lobar bronchi. Meanwhile the laryngeotracheal groove is being separated from the esophageal portion of the gut by a wall that moves progressively upward from the level of the bronchial buds to the larynx. As each lobar bronchus continues to grow it divides dichotomously. By the 36th day all ten segmental buds have appeared, giving the exterior of the lung a scal-

loped appearance. By the 40th day several additional generations of branchings have appeared, so that a model of the bronchial tree resembles great clusters of grapes.

This period of branching of epithelial tubes continues through the fourth month of fetal life and is known as the glandular period. About 16 to 26 generations of branching are then established. The last seven of these are lined by cuboidal epithelium. Between the fourth and sixth months—the canalicular period—capillaries protrude into the lumina of the more peripheral bronchi, pushing connective tissue fibrils ahead of them to separate the cuboidal cells. Such protrusions give rise in time to the walls of alveoli. At six months there are no alveoli as yet, but the number of capillaries protruding into the lumina is sufficient to support for several hours the life of an infant born prematurely at this age. In the alveolar period—seven months to term—vascular walls have protruded far enough into the lumina to outline shallow alveoli. From this time on the premature infant is viable.

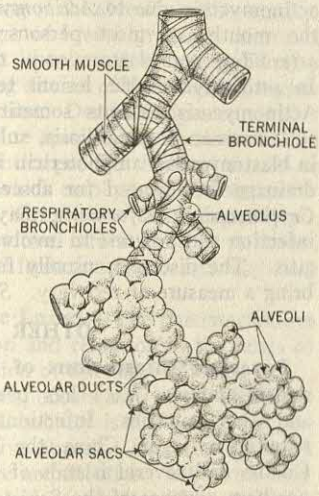

FIG. 6.—TERMINAL RESPIRATORY UNITS OF BRONCHIAL TREE

Obviously, birth is another critical period. The first respirations expand only a limited area. Full expansion requires several days, and sometimes weeks. Not infrequently portions of the lung never dilate (congenital atelectasis).

In premature infants, and those delivered by caesarean section, a hyaline membrane of unknown origin sometimes lines the alveoli, preventing respiration. Nor is it known whether aspiration of amniotic fluid before birth is a normal or abnormal occurrence. These and other problems dealing with respiration at birth await solution.

M. S. Dunnill has estimated that from birth to maturity the lung volume increases from 0.2 to 5.5 litres, that the number of alveoli increase from 24,000,000 to 296,000,000, and that the air-tissue interface (for exchange of gases) increases from 2.8 to 75 sq.m. How this is accomplished is only just beginning to be understood. At birth the only alveoli present are located in the very end branches of the tree, in tiny clusters of alveolar sacs 1 mm. in diameter. Within two months new alveoli appear along the bronchioles in a centripetal direction so that what were smooth respiratory bronchioles become transformed into alveolar ducts and what were the terminal bronchioles become transformed into respiratory bronchioles. It seems unlikely that growth is accompanied by the formation of new acini.

RESPIRATORY SYSTEM, DISEASES OF. Respiratory diseases may involve the upper respiratory tract from the nose, with its accessory sinuses, through the pharynx and larynx to the lower respiratory tract, which includes the trachea, bronchi and lungs. From beginning to end the mucous membrane of the entire tract is continuous. The anatomy and physiology of the respiratory tract are described in the articles RESPIRATORY SYSTEM, ANATOMY OF and RESPIRATION. This article is concerned mainly with diseases of the lower respiratory tract. For the upper respiratory system, *see* NOSE, DISEASES OF and THROAT, DISEASES OF. The diseases affecting the lungs are approached somewhat differently in LUNG, DISEASES OF; and PLEURA, DISEASES OF deals with the disorders specifically affecting the pleura. An inflammation of the lung from any cause may be called pneumonia, hence *see* also PNEUMONIA.

Disease Barriers.—Normally, inspired air is warmed and moistened as it passes over the nasal turbinates, which act as baffles. This mechanism is interfered with when infection or allergy causes swelling of the mucous membrane. Particles in the inspired air are usually deposited in the nose, from which they are eliminated. A circle of lymphoid tissue surrounds the pharynx, acting as a barrier against the dissemination of infection. The mucous membrane of the trachea and bronchi is supplied with minute hairs, the cilia, which beat upward away from the lungs. This cleansing device raises to the pharynx inhaled foreign particles, which can then be expectorated. Toxic agents may slow or paralyze ciliary action; dehydration or infection may so thicken the secretions that the cilia cannot beat freely. Some noxious particles actually reaching the alveoli (air sacs) of the lungs are engulfed and disintegrated by special cells and then brought to the ciliary stream. Cough is a mechanism for forcible ejection of foreign matter and infected secretions.

Interference with any of these mechanisms predisposes to disease. In addition, there are local and general factors of resistance involving nutrition, hormones, previous experience with disease, chilling, unconsciousness due to anesthesia or inebriation, etc.

INFECTIONS

Infections can be grouped most easily by causative organisms.

Viral Diseases.—Great difficulty occurs in attempts to correlate respiratory diseases with their viral causes. One virus may be responsible for several different illnesses, and one disease may be caused by several different viruses. This is a field of active research, and new viruses are being discovered.

Influenza has a short incubation period and occurs in epidemics, usually of relatively minor significance but occasionally in pandemics of great severity, as in 1918 and 1957. The later world-wide influenzal outbreak was caused by a substrain of type A virus named the Asian strain because the first recognized cases occurred in the Orient. There is no effective treatment for pneumonia produced by the influenza virus. Total prevention (as for smallpox, yellow fever, and rabies) is not available, but partial control may be achieved through vaccination, provided the responsible strain has been included in the vaccine. Antibodies against one influenza virus are ineffective against another type of the same strain. One of the great medical feats of the 20th century was the world-wide cooperation that resulted in the prompt identification of the Asian

strain of type A influenza virus, its incorporation into vaccines, and the use of vaccine on a mass scale so that protection was available immediately during the 1957–58 Asian influenza epidemic. Immunity from an attack of influenza is short-lived. (*See* also INFLUENZA.)

Another viral disease is pleurodynia, caused by the Coxsackie B virus. It occurs in small epidemics and is associated with severe chest pain made worse by deep breathing.

Primary atypical pneumonia is caused by more than one virus, is characterized by a normal white blood cell count (as are most viral infections) and by the presence of cold hemagglutinins, antibodies rarely present in other diseases. Like all viral diseases, it is resistant to treatment.

Rickettsial Pneumonias.—Bronchopneumonia may occur in louse-borne typhus (*q.v.*), a disease of world-wide distribution caused by *Rickettsia prowazekii.* Pneumonitis is a feature of many cases of Q fever (*q.v.*), a disease caused by *Coxiella burnetii* and first recognized in Australia. It is transmitted mostly by inhalation through occupational exposure to infected sheep, cattle, or goats, or by working with the rickettsiae in the laboratory. Many cases have been reported from California, Montana, and Texas as well as from Africa, Europe, the Middle East and Panama. The rickettsial diseases respond well to treatment with the tetracyclines or chloramphenicol.

Bacillary Infections.—The commonest bacillary infections of the nasopharynx are due to hemolytic streptococci and staphylococci, and to pneumococci.

(*See* also BACTERIA.)

Streptococcal sore throats are of great significance, since serious distant effects include kidney infections and flare-ups of rheumatic fever, with its possible sequel of rheumatic heart disease. Fortunately, excellent antibiotic treatment is available, penicillin being most effective. Early diagnosis is important, and for persons with a history of rheumatic fever prophylactic drug therapy during cold weather is desirable.

Staphylococcal infections occupy a major place among the pneumonias because of their rapid and often fatal course. The emergence of staphylococci resistant to many of the most potent antibiotics has presented a grave problem in treatment. Many staphylococcal infections are acquired in the hospital: resistant staphylococci have been cultured from throats and fingernails of hospital personnel, from air emerging from hospital laundry chutes and operating rooms, from blankets and from "clean" glasses and water bottles delivered to patients. Most hospitals have committees which not only review each case of staphylococcal infection but also draw up housekeeping procedures designed to prevent the transmission of such infections.

Pneumococcal pneumonias appear to be less common than they once were. It is not apparent whether this is due to a true reduction in prevalence or to the fact that cases are being successfully treated at home with the many antibiotics available. Friedländer's pneumonia, caused by Friedländer's bacillus, *Klebsiella pneumoniae,* remains a grave infection seen mostly in older men, frequently in alcoholics or grossly malnourished persons.

Tuberculosis.—This is a disease with a declining death rate; however, in many areas, including Eastern Europe, Asia, and the western Pacific islands, tuberculosis is still rampant. In remote or overpopulated places diagnosis is often erroneous and statistics are inadequate, so that the true magnitude of the problem is unknown.

The number of persons suffering from active tuberculosis constitutes a better measure of the problem than the number of persons dying from the disease, particularly since modern treatment is effective. Though morbidity rates are slowly diminishing in the economically advanced countries, the problem remains of considerable magnitude. For a full discussion of this disease, *see* TUBERCULOSIS.

Fungus Infections.—Certain geographic areas are endemic foci of fungus diseases, many of which affect the lungs. In the U.S., portions of the South and the whole Mississippi Valley have high rates of infection with *Histoplasma capsulatum.* A ten-year study of histoplasmin and tuberculin reactors among kindergarten children in Kansas City, Mo., reported by L. E. Wood and his co-workers in 1958, revealed a higher prevalence of histoplasma infection than of tuberculous infection. Histoplasmosis is a serious problem in these endemic areas. Its behaviour closely resembles that of tuberculosis. Amphotericin B gives promise of being effective in therapy. As with tuberculosis, some cases of histoplasmosis run a benign course. Miliary calcifications result from benign disseminated disease; their X-ray appearance remains unchanged over years. Localized epidemics of histoplasmosis have occurred in association with the soil of chicken houses, and the disease has been reported in association with bat dung.

In the western and southwestern United States, northern Mexico and certain areas of South America, infection with *Coccidioides immitis* is prevalent; nearly all residents are infected, many without ever having had symptoms. Coccidioidomycosis is contracted by inhaling chlamydospores (the *Coccidioides* reproductive organs) in dust. About half the cases exhibit respiratory symptoms. The pneumonitis which develops may clear entirely or may leave characteristic thin-walled cavities. Small cavities tend to close slowly. Larger cavities frequently give rise to expectoration of blood-stained sputum and occasionally rupture; for this reason surgical removal may be advised. The drug amphotericin B is sometimes helpful. Coccidioidomycosis may be prevented by avoiding endemic areas, particularly during dry, dusty seasons.

Less common fungus diseases of the respiratory tract include actinomycosis, due to *Actinomyces bovis,* a fungus harboured in the mouths of most persons; nocardiosis, due to *Nocardia asteroides;* and blastomycosis, due to *Blastomyces dermatitides.* In actinomycosis the lesions tend to penetrate the chest wall. Actinomycosis patients sometimes are helped by penicillin or sulfadiazine; in nocardiosis, sulfonamide therapy alone is used; in blastomycosis, amphotericin B is the drug of choice. Surgical drainage is indicated for abscesses. Cryptococcosis, caused by *Cryptococcus neoformans,* may begin with a mild respiratory infection and progress to involvement of the lungs and to meningitis. The disease is usually fatal, though amphotericin B may bring a measure of recovery. *See* also FUNGUS INFECTIONS.

OTHER DISEASES

Parasitic Infestations of the Lung.—Chronic pulmonary schistosomiasis (*q.v.*) has been reported from Egypt, Brazil and other countries. Infections with blood flukes are widely distributed in Japan, China, the Philippines, Africa, Brazil, Dutch Guiana and several islands of the West Indies. With the slow northern advance of the *Schistosoma,* the disease has come to be of interest in the United States. Exposure occurs through contact with water infested by snail hosts, through bathing, laundering, etc.

Amoebiasis occurs all over the world, mostly in the tropics and where sanitation is poor. Prevention consists of avoiding contaminated water and raw foods which may have been washed with such water. Pulmonary abscesses occur secondary to amoebic abscesses of the liver. (*See* also PARASITOLOGY.)

Allergic Diseases.—Vasomotor rhinitis (cold in the head), hay fever, and bronchial asthma are a triad of common allergic diseases of the respiratory tract.

Vasomotor rhinitis, characterized by copious watery nasal discharge, is nonseasonal, in contradistinction to hay fever, which is seasonal and caused by pollens. Hay fever is associated with sneezing, itching of the eyes and nose, outpouring of watery secretions from the eyes and nose and an abrupt onset when the causative pollen first becomes airborne. While it is not in itself serious, it is annoying, interferes with sleep and appetite as well as with the normal functions of the nasal mucosa and thus predisposes to infection. (*See* also COLD, COMMON; HAY FEVER.)

Bronchial asthma, the most serious of the allergic diseases of the respiratory tract, is characterized by sporadic attacks of wheezing due to spasm of the involuntary muscles in the bronchial walls. The wheezing is bilateral, intermittent and changeable, in contrast to the unilateral fixed wheeze of tumour, ulcer or scarring of a bronchus. Clear tenacious secretions are difficult to raise

Allergies include a wide variety of exogenous materials such as dust and feathers, but, especially in cases in which the onset of asthma occurs in middle age, endogenous bacteria are often causative. There are usually multiple factors. The actual attack may be precipitated by an emotional upset, a sudden marked change of temperature or a respiratory infection. During an attack air hunger is acute, the spasm of the smaller bronchi exerting a ball-valve effect by which air gets in but cannot get out because the spasm increases the normal shortening and narrowing of the bronchi on expiration. The mucoid secretions may actually plug some bronchi. Occasionally the patient goes into a serious prolonged life-threatening episode called status asthmaticus. Most attacks of asthma can be successfully treated by adrenaline or adrenalinlike drugs and can be averted by avoidance of allergens, infections, rapid changes of temperature and by the achievement of emotional tranquility. While recurrent asthmatic attacks are usually not grave, they lead over the years in many cases to a state of chronic overdistention of the lung and to emphysema. (*See* also ASTHMA.)

Chronic Bronchitis and Emphysema.—Repeated attacks of acute bronchitis (*q.v.*) predispose to chronic bronchitis characterized by chronic cough productive of sputum. Such persistent productive cough tends to be associated with recurrent bouts of respiratory illness, during which fever is often present and expectoration increases. Ultimately, wheezing is heard and, in an unknown but probably significant percentage of cases, overdistention of the lungs with thinning of the alveolar walls—emphysema (*q.v.*)—develops. Shortness of breath gradually increases until the slightest physical effort is followed by great difficulty in breathing. This major crippling disease of the lungs is progressive and results in total incapacitation. Death finally occurs either from heart failure or from an acute episode of infection. Drugs relieve bronchospasm, and antibiotics produce brilliant results in combating the pneumonias from which emphysema patients suffer recurrently, but there is no cure. Criteria for early diagnosis are lacking. In the absence of definitive information as to cause, measures which prevent bronchial irritation and cough may help in prevention.

Occupational Diseases of the Lungs.—The pneumoconioses are lung diseases due to inhalation and retention in the lungs of industrial dusts, with the production of fibrosis. Silicosis (*q.v.*), the most important pneumoconiosis, occurs as a result of inhalation of fine particles of quartz. Disability is due to the emphysema associated with the progressive fibrosis. Silicotics are more susceptible to tuberculosis than are nonsilicotics. Asbestosis may develop in those exposed to inhalation of asbestos fibres. Over a protracted course, it involves the pleurae and pericardium—the coverings of the lungs and heart—and causes heart failure. Prevention of inhalation of such dusts is important, since there are no successful cures once the fibroses have actually developed. Berylliosis, an acute disease associated with extreme shortness of breath, was largely caused by the inhalation of beryllium phosphors in the manufacture of fluorescent lamps; cases even occurred in persons living in the neighbourhood of such plants. The industry has changed its manufacturing process so that fewer and fewer cases are seen. Treatment with steroid hormones is suppressive. A number of other less common pneumoconioses occur due to exposure to diatomaceous earths, finely divided tin, etc.

"Farmer's lung" is an acute pneumonitis resulting from the handling of a variety of dusty, moldy, organic materials. Repeated exposure produces recurrence. "Silo filler's disease," another uncommon disease reported among agricultural workers, is a pneumonitis apparently caused by the inhalation of certain oxides of nitrogen. Bagassosis occurs as a result of inhaling bagasse, a residue from sugar cane. (*See* also DANGEROUS OCCUPATIONS; PNEUMOCONIOSIS.)

Nonoccupational Disseminated Diseases of the Lung.—Sarcoidosis, a widespread disease which often involves the lungs, is characterized frequently by dramatic bilateral chest X-ray abnormalities in the presence of few or no respiratory symptoms. The causative agent is unknown. Most of the patients have come from the southeastern United States, and the U.S. Public Health Service has postulated a relationship to some of the pollens of pine forests in that area.

M. Bergmann and his co-workers applied the term thesaurosis to a disease they reported, implying that it resulted from the storage of macromolecules of resins used in hair spray and inhaled by the sprayer. Two cases of bilateral lung disease were found associated with the use of hair spray. Bergmann produced experimental granulomas in guinea pigs by injecting into them the residue from a well-known hair spray suspended in saline solution.

Tumours.—A dramatic rise in the incidence of lung cancer occurred after about 1930 in the United States, England and Wales, Australia, Canada, Denmark, Japan and Turkey. The rise was much more marked in men, among whom, in the United States, lung cancer became the commonest cancer. A statistical association with smoking has been pointed out by numerous British and U.S. investigators. Since lung cancer is found in urban rather than in rural areas, the possible causative role of air pollutants needs study also. As of the mid-1960s the only cure for the disease was surgical removal before distant spread could occur. Five-year survival rates reported by surgeons were less than 10%.

See CANCER; TUMOUR; LARYNGITIS; *see* also references under "Respiratory System, Diseases of" in the Index.

(K. R. B.)

RESSEL, JOSEF LUDWIG FRANZ (1793–1857), an inventor of the screw propeller for steamships, was born at Chrudim, Bohemia, June 29, 1793. He first tried a small boat fitted with a screw propeller at the bow, turned by two men (1826). Ressel obtained his Austrian patent in 1827, and a British patent, believed to have been also on his behalf, was obtained in 1828 by Charles Cummerow. Ressel tried his steamboat, the "Civetta" of 48 tons' displacement, at Trieste in 1829. The screw propeller was of copper, 5 ft. 2 in. diameter, and placed at the stern. The vessel attained a speed of six knots. Ressel died of malaria in the night of Oct. 9–10, 1857, at Laibach (now Ljubljana, Yugos.). In 1924 his native town, Chrudim, raised a monument to his memory.

See Ferdinand Thomas, *Josef Ressel, der Erfinder der Schiffsschraube* (1880).

(H. P. St.)

REST: *see* MUSICAL NOTATION: *Development of Notation.*

RESTAURANT. The word restaurant, from the French *restaurer* ("to restore"), was originally used to describe a nourishing soup. It came later to be used for taverns where this soup, with other food, was served to the public.

The first dining room to be known as a restaurant was opened in 1765 by A. Boulanger, a soup vendor in Paris. Referring to his soup as a *restaurant* ("restorative"), Boulanger inscribed on the sign above his door the Latin phrase *Venite ad me; vos qui stomacho laboratis et ego restaurabo vos* ("Come to me, you with laboured stomachs and I will restore you").

Early Inns and Taverns.—Inns and taverns have probably existed since the beginning of trade and commerce. In ancient Greece the *leschai,* primarily a local club, served meals to strangers as well as to its local members. By the 5th century B.C. there were sumptuous hostelries called *phatne* that served a local and transient clientele of traders, envoys, and government officials. Hotels had separate dining rooms in which the excellence of the food varied with the chef. Meat from sacrificial altars was served, a practice that continued in Greece and Rome until Christian times, and winecake, honey, dried figs, cheesecake, ham, and sweetbreads were among the dishes available.

In ancient Rome no man of any social standing could be seen in a tavern, although one type of establishment, the *lupanar,* flourished behind locked doors on the quietest of side streets, and men with veiled heads entered in the dark of night to dine, drink, or gamble. Nor was the reputation undeserved, for the *deversoria, tabernae, cauponae,* and *bibulae* of republican and imperial Rome were haunts of the jaded and degraded at best, and of criminal types at worst. Yet cooked delicacies and full meals were traditionally served in the *caupona* (low-class inn) and *taberna meritoria* (better-class tavern). These were long chambers having vaulted ceilings, with serving boys standing at semiattention and the proprietor sitting at a raised platform at one end. The walls were decorated with inscriptions and decorations scrawled with

burned sticks. Often food was on display near the front—eggs, goose liver pâté, ham, cheese, fowl, and game—to draw customers. The fare served inside was more likely to be sluggish pea soup, chick-peas fried or in porridge, twice-cooked cabbage or raw vegetables soaked in vinegar, or boiled sheeps' heads, all highly seasoned with garlic, onions, asafetida (a gum resin of certain Oriental plants), and pungent sauces, the commonest base for which was *garum,* the juice from putrid fish entrails.

The restaurants of Roman England were the *cauponae* and the *tabernae* of Rome itself. These were followed by alehouses, run by women (alewives) and marked by a broom stuck out above the door, and in the 12th century by cookshops, from which most customers carried away cooked meats, though they could also eat them on the premises.

The English inns of the Middle Ages were sanctuaries of wayfaring strangers, cutthroats, thieves, and political malcontents. The tavern, the predecessor of the modern restaurant, originated the custom of providing a daily meal at a fixed time.

By the middle of the 16th century the dining-out habit was well established among townsmen of all classes. Most taverns offered a good dinner for 1*s.* or less, with wine and ales as extras. Tobacco was also sold after its introduction into England in 1565. Taverns offered companionship as well as refreshment, and some of the better houses became regular meeting places and unofficial clubhouses. Among the more famous London taverns of Tudor times were the Mermaid, frequented by Ben Jonson and his friends; the Boar's Head, associated with Shakespeare's Sir John Falstaff; and the Falcon, where actors and theatre managers of the day gathered.

Samuel Sorbière, a noted French scientist, observed on a visit to England in 1663:

> the English are not very Dainty; their Tables are covered with large Dishes of Meat; they are Strangers to Bisks and Pottages; their Pastry is course and ill-baked; their Stewed Fruits cannot be eat; they scarce ever make use of Forks or Ewers, for they wash their Hands by dipping them into a Bason of Water. There is scarce a Day passes but a Tradesman goes to the Alehouse or Tavern to smoke with some of his Friends, and therefore Publick Houses are numerous here.

César de Saussure in 1725 on a visit from Switzerland observed:

> in London there are a great number of coffee houses, most of which are not over clean or well furnished owing to the great number of people who resort to these places and because of the smoke, which would quickly destroy good furniture. In these coffee houses you can partake of chocolate or tea or coffee, and all sorts of liquors, served hot, also in many places you can have wine or punch or ale. What attracts enormously are the gazettes and other public papers. . . . Workmen habitually begin the day by going to a coffee house in order to read the latest news.

Certain "ordinaries" run by Frenchmen in London seem to have been closer to the modern idea of a restaurant than the contemporary taverns and coffeehouses. The set dinner of one or two dishes was the 18th-century equivalent of the modern *table d'hôte* restaurant meal.

In France Catherine de Médicis, with the help of Italian cooks, revolutionized cookery, and by the time Boulanger founded his restaurant, shortly before the French Revolution, Frenchmen had become discriminating, and nobles vied with each other over the excellence of their cooks. During and after the Reign of Terror, the shortage of nobility created a surplus of cooks, and to survive many of these opened their own eating places. By 1804 Paris had from 500 to 600 restaurants, and to dine in them had become the fashion.

The identity of the first public dining place in the U.S. is obscure. It is certain, however, that it was known as an inn, tavern, or ordinary, names not always interchangeable. It is probable that taverns appeared in the U.S. almost as soon as the first Dutch settlers arrived. Boston's first tavern, Cole's, opened its doors in 1634. New York's first tavern was opened in Dutch Colonial days by Governor Kieft, who stated that he was tired of entertaining strangers and travelers in his own home and thus opened a tavern to lodge and feed them. The building became New Amsterdam's (and later New York's) city hall and was used for that purpose until the present city hall was built in the 1880s.

Modern Restaurants.—*France.*—French cuisine is generally agreed to be the luxury cuisine of the world, and in the 20th century it has been offered in many first-class restaurants and hotels around the globe, so much so that in some cities, Rio de Janeiro, for example, native cuisine is almost nonexistent in restaurants catering to an international clientele. Among the highlights of French cuisine are three varieties of steak: *chateaubriand,* or sirloin; *tournedos,* or filet mignon; and *entrecôte,* the French minute steak. French roasted and grilled meats are first-rate, as are their seafoods. The French are famous for delicate sauces for both meats and vegetables, omelets and soufflés, and stews, such as *pot-au-feu* and *bourguignonne.*

Of the European restaurants, those of France have the most individual character. Paris, the gourmet's paradise, has more than 3,000 restaurants, and of these, the old established places are still the most reliable. It is very difficult to find bad cuisine in Paris or, indeed, anywhere in France. Most provincial towns have well-known restaurants that specialize in a local dish. Southern France, particularly the Riviera, abounds in restaurants and cafés of all standards.

Italy.—Italian cuisine embodies an almost endless series of regional delicacies. The cooking of Emilia-Romagna in the north is said to be Italy's best. *Tagliatelle al ragu* (thin slices of *pasta* made with eggs and served with a magnificent ragout) is one of the region's famous dishes, along with fine seafoods and Parmesan cheese dishes. Tripe *alla Romana, gnocchi* (noodles with cheese and tomato sauce), and *saltimbocca* (veal and ham slices fried in butter with sage leaves) are typical Roman dishes. Italy's finest restaurants are found in Venice, Turin, and Rome.

Greece.—The restaurants of modern Athens—specializing in such national delicacies as *dolmadakia* (vine leaves stuffed with seasoned rice, meat, and onions), *moussaka* (eggplant and meat served with cheese and tomato), and *tyropitta* (Grecian cheesecake)—are often small, delightful, tavernlike places where native games, singing, and dancing go on with meals. The hotel dining rooms serve the best in regional and Continental dishes.

Switzerland.—Switzerland is renowned for its restaurants, where cuisine is for the greater part in the French style. The Swiss are expert organizers, meticulously clean, and provide first-class waiters.

Germany.—The large cities of Germany have good restaurants; those of the top-rate hotels are usually renowned. Most of the restaurants along the Rhine and the Moselle and, indeed, throughout the wine-producing country, tend to concentrate on local wines.

Portugal.—Portugal, with its ancient forts, castles, and monasteries converted into hotels and restaurants, offers reasonably good food with mostly French cooking. In most Portuguese restaurants the price of the meal includes a carafe of wine. The state-owned *pousadas* ("inns") are difficult to better.

England.—The late 19th-century tavern was replaced by the ornate hotel dining room and by the restaurant itself, which came to England under its French name in the 1880s. The tavern ceased to be the haunt of fashionable gentlemen, who preferred their clubs (*see* CLUB), and out of the old tavern emerged today's public house. In 1884, the first tea shop was opened near London Bridge, and ten years later a similar shop was opened by J. Lyons & Co. Ltd., in Piccadilly. These were the forerunners of vast chains of tea shops, where first teas and later more substantial meals were served. Their immediate popularity was due largely to women, who could not frequent taverns or fashionable restaurants unless escorted. The first department store restaurant was opened in Whiteley's in 1873, and the idea spread rapidly to other stores.

After 1951 restaurants of all types appeared, specializing in foods of all nations. Coffee bars flourished, though a far cry from the first English coffeehouse opened in Oxford in 1650. Espresso bars (so-called from the method of making coffee in machines originally imported from Italy), following the first of the coffee-houses, sprang up overnight, until almost every district in London boasted its coffee society centre, and the espresso bar became a national institution. The snack bar and the milk bar, which originated in the U.S., also became extremely popular, as did cafeterias.

Typical English food compares well with the delicacies of any nation. Savories like Welsh rarebit and Scotch woodcock; entrees like roast beef and Yorkshire pudding, steak and kidney pie, roast

lamb and mint sauce, mixed grill and Dover sole; desserts like trifle, delicately flavoured puddings, and egg-custard pie are served.

United States.—The decades after World War I saw the decline of the exclusive restaurant. Though there are still many fashionable eating places, the largest number of restaurants have become successful by serving meals in pleasant surroundings and at popular prices. By far the preponderance of restaurants and coffee shops offer regional dishes, and if there is any one dish which might be tagged the national dish it is probably the hamburger, available from the smallest hamlet drugstore counter to the most lavishly endowed restaurant, although in the latter it might be disguised on the menu with a French pseudonym such as *bifteck haché*.

Several types of restaurants that are characteristically "American" include the cafeteria, the steak house, the seafood house, and the roadside restaurant. Perhaps the most popular foods offered are grilled dishes, prepared over a charcoal fire or under an open flame.

Many restaurants throughout the country offer the cuisine of other nations. The best known "foreign" restaurants are French, Italian, and Chinese. Most Italian restaurants are Neapolitan, or created in the style of Naples, relying heavily on tomato sauces and spices, as opposed to North Italian cuisine, which is subtler and closer to the French. Chinese restaurants are mainly Cantonese —this is true throughout the world, although it is only one of five schools of cooking in China. Within recent years there has been an outcropping of Polynesian, Japanese, and Mexican restaurants, principally in metropolitan centres. Polynesian food has enormous appeal because of its flavour and its exotic nature and presentation (*e.g.*, food served in hollowed-out pineapple or coconut shells). First-class Japanese restaurants offer a delicate cuisine. The most popular dish is beef sukiyaki, made with wafer-thin slices of beef, soy sauce, mirin (a type of wine), bean curd made of fermented soy beans, and vegetables. Much of the Mexican cuisine served in the nation's restaurants is Mexican by inspiration but American in execution. Among the most popular dishes are tamales, chili, and guacamole, a dish made with pureed avocado and chopped onion or garlic.

Recent Trends.—Restaurant owners have been beset with relatively new problems involving labour and cost control that have affected standards of service and the quality of food served, especially in the *grand luxe* establishments. Another major problem is a lack of training facilities for chefs and for the service staff, although Europe has many trade schools, and several universities in the U.S. offer catering courses. Until recent decades chefs trained in the European tradition spent months, and even years, at various stations where sauces, roasts, fish, desserts, and other items were prepared. There has been a decline in the number of those entering the cooking profession in both Europe and the U.S.

In the mid-1950s the average cost per seat of existing restaurants in the U.S. was about $500; in 1960 the per-seat cost of restaurants planned was about $3,000. With increased minimum wages for kitchen and dining room staffs, it became necessary to reduce expenditures for labour, equipment, and food. Several decades ago there was little accounting for food costs in first-rate kitchens, but cost control has become a vital factor in restaurant operation. Also, a more weight-conscious public prefers less rich foods.

Both the cafeteria and the specialty house were brought into being by rising costs. The cafeteria meets the problem by serving simple yet good food quickly to many people, using few employees. Cafeterias, long popular in the U.S., are now becoming more popular in Europe. Most French cafeterias provide wine in carafes and offer *le service quick*. The specialty house meets costs by limiting items on the menu, thus reducing the outlay for equipment and labour.

The early 1960s saw the large-scale refurbishment of hotel dining rooms and in many cases their conversion into lower-overhead specialty houses in an attempt to restore the dining room to its former preeminence and to help hotels meet the competition of motels and motor hotels, whose eating facilities are usually minimal.

RESTIF, NICOLAS EDME (RESTIF DE LA BRETONNE) (1734–1806), French novelist, a forerunner of Balzac and Zola, rated above Rousseau by Paul Valéry, compared to Defoe by George Saintsbury, to Proust by Havelock Ellis, and to André Gide by Marc Chadourne, his biographer, is a much debated figure in the history of literature and ideas. Born at Sacy, Yonne, on Oct. 23, 1734, he later went to Paris, where he worked as a journeyman printer and where, in 1760, he married Anne (or Agnès) Lebègue.

Restif produced about 200 volumes, many of them printed by his own hand, and his writings cover a wide range of subjects with astonishing licence. He has been heralded by Chadourne as a prophet who foreshadowed the atom, the sputnik, flying men and air squadrons, the missile that shoots into interplanetary and interstellar space, bacteriology, atomic energy, the Superman, dictatorship, totalitarianism, the United States of Europe, social security, and Communism. But he has also been recognized as "the Casanova of the stews, the Rousseau of the gutter, or Balzac's caveman." His life and loves, real or fancied, have given him notoriety. He may not have been a fetishist or a pervert in the technical sense, but his vindication of incest was no mere rationalist exercise; after the age of 45 he felt compelled to convince himself that he was the father of the women he took as his mistresses. His eroticism, which is tinged with mysticism, and his emotional lucidity are revealed in his autobiography, *Monsieur Nicolas* (16 volumes, 1794–97), much of which is set in the Parisian underworld of the period. It is his portrayal of 18th-century society that has led to his being called the Zola of his age.

Gérard de Nerval (*q.v.*), who thought of himself as the reincarnation of Restif, retold in *Les Illuminés* (1852) the story of Sara, one of the most striking episodes in *Monsieur Nicolas*. But as, for instance, when dealing with the story of the actress *la belle Guéant*, Nerval, in spite of much research, failed to distinguish fact from fiction, a task which Restif's vivid imagination has rendered difficult.

As well as *Monsieur Nicolas*, Restif's works include *Le Pied de Fanchette* (1769); *Le Pornographe* (1769), a plan for regulating prostitution said to have been carried out by the Emperor Joseph II and to have inspired authorities in other continental countries; *Le Paysan perverti* (1775) and *La Paysanne pervertie* (1784), recast and republished as *Paysan-Paysanne perverti* (1784); *La Vie de mon père* (1779); *Mes Inscriptions* (a journal for 1780–87, discovered in 1887); *Les Contemporaines* (42 volumes, 1780–85; to which should be added the 23 volumes of *Les Françaises, Les Parisiennes*, 1786–91); and *Ingénue Saxancour* (1785). The first editions of most of his books have long been bibliographical curiosities for their rarity, the beautiful and curious illustrations they contain, and the quaint typographic system adopted. Just before his death (in Paris on Feb. 3, 1806), Napoleon gave Restif a place in the ministry of police. His funeral service, in Notre Dame on Feb. 5, was attended by 1,800 persons; they included Louis de Fontanes and the comtesse de Beauharnais, who had befriended him.

RESTRICTIVE TRADE PRACTICES (REGISTRAR AND COURT). In the United Kingdom, the Restrictive Trade Practices Act, 1956, provided for the appointment of a registrar of restrictive trade practices and for the establishment of a Restrictive Practices

Court which was to be a division of the High Court (*q.v.*). The act rendered illegal the practice of collective resale price maintenance and provided for the reconstitution of the Monopolies Commission which would deal only with monopolies and other practices exempted from registration (sec. 7 and 8) and not to be investigated by the new court (*see* MONOPOLIES COMMISSION).

The registrar compiles a register of restrictive trading agreements and brings proceedings before the Restrictive Practices Court. Any two or more persons producing or supplying goods or carrying out any process of manufacture within the United Kingdom are required to register any agreements between them concerned with prices, conditions of sale, quantities of the goods to be produced or supplied, processes of manufacture, and persons to be supplied. Various exemptions from registration are made, notably in the case of agreements concerning goods supplied solely for export. The register of agreements is open to the public, except for a special section containing information relating to secret processes, etc. (sec. 11). The court consists of five judges and not more than ten other members qualified by virtue of their knowledge of industry, commerce, or public affairs. The court can sit in divisions, each consisting of at least one judge and two other members.

The registrar must refer to the court agreements on the register (the Board of Trade can give him directions regarding the order of cases to be taken). The court declares void restrictions contrary to the public interest and makes an order restraining the parties from giving effect to the agreement. Agreements are contrary to the public interest unless they pass through one of the seven "gateways" (sec. 21). These gateways are concerned with the effect that the removal of the restrictions would have on the quality of the goods to which the restrictions apply, the level of unemployment in an area, the export trade, etc. The court must also be satisfied that on balance the agreements are not unreasonable, having regard to any detriment that they cause to the public.

The 1964 Resale Prices Act gave the registrar and the court the further duty of considering those cases of resale price maintenance in which exemption was sought from the general prohibition of this practice contained in the act. In consequence the maximum number of judges was increased.

RESURRECTION: *see* ESCHATOLOGY; JESUS CHRIST.

RESURRECTION PLANT (*Anastatica hierochuntica*), a small herb of the family Cruciferae, called also rose of Jericho, native to Arabia, Iran and Egypt.

Upon the ripening of the seeds during the dry season, the leaves fall off and the branches curve inward so that the dry plant assumes a globular form. It then rolls about in the manner of a tumbleweed until the rainy season. When wet the branches unfold and it assumes for a time the appearance of a living plant.

The name is also given to two other plants. One is the mosslike *Selaginella lepidophylla* which also dries up into a ball and expands when wet. It is called also bird's-nest moss and is found from Texas southward to Peru. The other is the resurrection fern (*Polypodium polypodioides*), the commonest epiphytic fern in Florida.

RETAILING, the business activity concerned with the sale of merchandise directly to ultimate consumers; *i.e.*, to people who buy for personal or household use rather than for reprocessing or resale. In industrialized countries most retail sales take place in fixed establishments, or stores, especially devoted to this activity. However, there is also some nonstore retailing, including mail-order and telephone business, sales by house-to-house canvassers, street peddling and sales from trucks, carts and automatic vending machines.

General discussions of retailing often include all stores and shops catering to the general public. Strictly speaking, however, personal service businesses, such as barber shops, beauty parlors and dry cleaners, are not part of the retail structure because they derive little or none of their income from the sale of merchandise. Government reports on retail trade activities usually exclude the receipts and expenditures of such establishments; in some cases, they also exclude restaurants and other establishments where food and drink are served.

Importance of Retailing.—The proportions of total national income and labour force associated with retail trade vary greatly from country to country. In general, retail trade is quantitatively most significant in nations with high material living standards, high degrees of industrialization and marked economic specialization. Because consumers in such countries look to the marketing system for practically all the goods they use, their retailers handle a larger total output than is the case in lands where most people support themselves wholly or partly through subsistence agriculture. In spite of the rise of self-service stores, discussed below, retailing has not been as susceptible as either manufacturing or agriculture to the introduction of labour-saving methods, such as mechanization. Consequently, the growth of retail trade in industrialized countries over the years has caused a significant expansion of retail employment.

U.S. retail employment increased steadily from 1870 to 1950, rising from about 5% of the work force to about 12%, exclusive of restaurant workers. A somewhat similar increase occurred in Great Britain, although shortages and government controls sharply reduced retail employment during both World Wars I and II. British retailing absorbed about 10% of the labour force in the 1960s. Elsewhere, retail employment estimates made at various dates in the 1950s ranged from 6% to 8% for western Europe and Japan to substantially under 6% in India and considerably less than 1% to 3% in most portions of tropical Africa. However, the interregional differences in retail employment probably were not as marked as these last figures suggest. Many students of African and Caribbean economic structures believe that official reports seriously underestimate the number of part-time, self-employed and unpaid family workers in such areas.

There have been relatively few attempts at analyzing total national expenditures for retail distribution. Investigators have calculated that retail margins (selling prices minus cost of goods sold) account for nearly 30% of the final value of all goods sold by retailers in the United States and Great Britain. These margins, of course, included retailers' payments to firms in other industries for such purposes as transportation, occupancy and advertising equipment and services. Cox, Fichhandler and Goodman concluded that the retailers' own services (after subtracting all such disbursements to other firms) constituted about 18% of the final value of all commodities purchased by U.S. householders. The department of commerce has credited retailing as the source of about 10% of U.S. national income.

The significance of retail development is not entirely measurable in statistical terms. Retailers, especially innovating retailers, have played an active role in helping to stimulate the production and consumption of commodities, as well as performing the more passive role of bridging the gap between producers and consumers. A National Planning association study reported that a mail-order and department store chain which entered the Mexican market in 1946 helped foster that country's industrialization through assistance to consumer goods manufacturers and helped encourage the rise of a middle class through the provision of quality merchandise at reasonable prices. Large U.S. retail organizations served much the same function, particularly from 1870 to 1920, and so did European department store, multiple shop (chain store), and co-operative organizations.

History.—As a specialized business, retailing apparently grew out of the activities of roving traders and of craftsmen who made and sold utensils and ornaments in their dwellings. The considerable development of trade in early Mesopotamian and Egyptian civilizations and in Minoan Crete suggests that retail buying and selling were very common, although nothing is known

concerning the proportions of their populations that supported themselves through retailing alone. Even though their ruling classes scorned and despised all merchants, specialized shops were an important element in both Greek and Roman urban life.

After the fall of Rome, retailing declined in the western world along with the general reduction in living standards. Subsistence agriculture, homecrafts and the manorial system supplied most of the goods intended for personal consumption. The rest were distributed through periodic fairs and markets, crude shops and visits of chapmen (itinerant merchants). Later, retail stores assumed importance as living standards rose and a larger proportion of the population lived in cities and towns. However, the differences between even the most elegant shops of the early 19th century and their crude predecessors of the dark ages were largely matters of appearance and inventory. Retail organization and operating methods remained substantially unchanged, except for improvements in bookkeeping techniques, until about 1860. During the latter half of the 19th century, increasing urbanization, improved communications and increasing output of factory-made products provided fertile ground for the development of large retail organizations, including department stores, chain stores, mail-order houses and consumer co-operative societies.

The operating economies enjoyed by these large retailers at various stages of development have rested upon policies of both expansion and concentration. Savings resulted, on one hand, from spreading management and overhead costs over a wider assortment of goods, as in the case of department stores and supermarkets; over a larger number of locations, as in the case of chain stores; or over a combination of retailing, wholesaling and even manufacturing, as in the case of some chain stores and co-operative societies. On the other hand some large retailers have gained by concentrating upon popular, fast-selling merchandise, as in the case of discount houses and unit price (variety) chains; and by transferring some traditional functions of retailers to the consumer, as in the case of self-service stores.

A common pattern marks the history of each type of large-scale retailing, such as the department store. Each appeared first as a low-cost method of doing business and attracted trade largely through low prices. Each new method seemed an aggressive challenge to established ways of doing business. Conventional retailers and others reacted by bitterly attacking the new entrants as unfair competitors and as potential monopolists. This opposition abated as each new group exhausted its immediate opportunities for rapid expansion. Costs and prices rose, partially in response to competitive pressures that forced increasing investment to provide additional shopping conveniences, and gradually the share of total retail sales obtained by the new entrants stabilized or declined somewhat. Although every new type of retailing was once criticized as a threat to the independent merchants, those merchants still do the bulk of the total business in every country in which retail trade is not a government function.

Co-operatives.—Consumer co-operatives were the first of the large-scale innovations in retailing. The modern co-operative movement began in 1844 with a small grocery shop established by a group of impoverished weavers in Rochdale, Eng., although there had been many previous attempts at co-operation. It spread to Scandinavia and also to Switzerland, where a very aggressive retail chain, called Migros, was converted to consumer ownership in 1940.

The co-operative movement originally espoused two basic ideas: (1) democratic customer-owner control and participation in the work and profits of the enterprise; and (2) production for use instead of for profit, and hence, implicitly, elimination of expenses involved in attracting trade. The very growth of the movement forced some departures, in practice, from these principles. Membership control became more and more indirect, and the operations of the societies were increasingly entrusted to professional executives and staff. Adjustment to rising standards of living among the members, as well as competitive pressures, forced the co-operatives to carry larger assortments, particularly of luxuries and semi-luxuries, to advertise extensively and to build more attractive shops. The successes of British and European co-operatives seem to have resulted as much from the skills and abilities of the managers as from the fact of co-operative organization.

Department Stores.—A reorganization of the Bon Marché, a Parisian dry goods shop, created the world's first true department store (*c.* 1865). This example was soon followed by merchants in many U.S., British and northern European cities. The essential feature of department store organization was the delegation of responsibility and authority to subordinate executives. Each department head was made responsible for purchasing a related group of commodities and for overseeing their sale in a distinct section of the store. Thus department stores could offer much wider assortments of goods than the conventional shops in which only the owner or a few partners handled all supervisory and executive duties. Low prices, as well as large assortments, drew a large volume of trade, thereby providing reductions in operating costs that made the low prices possible. Department stores were also distinguished by the general use of fixed prices, clearly marked on the goods, instead of the bargaining process common to many smaller stores. This policy was not as rigid as is commonly assumed, however. Until 1940, for example, many U.S. department stores gave discounts to favoured classes of customers, such as teachers and clergymen. Eventually operating costs and margins increased, and much of the competitive threat these large stores had originally posed for small merchants waned. Department store margins in the U.S. rose from about 20% of selling price in 1900 to about 36% after World War II, and department stores as a group obtained only between 5 to 10% of total retail sales, both in the U.S. and in Britain.

Chain Stores.—Modern chain stores or multiples, *i.e.*, groups of separate shops under common ownership and direction, first appeared in the U.S. and Great Britain between 1850 and 1870. However, prototypes can be found in the string of Canadian trading posts established in the early 18th century by the Hudson's Bay company, in the Mitsui apothecary shops established in Japan around 1630, and even in ancient China and Pompeii. Chain organization clearly demonstrates the operating advantages and disadvantages of large-scale retailing. The chains have benefited in the following ways: (1) from being able to purchase both merchandise and supplies in the most economical markets, often going so far as to direct the manufacture of goods to their specifications; (2) from the employment of highly skilled specialists in many executive tasks; (3) from standardization of operating methods; (4) from spreading risks over many locations; (5) from an ability to experiment in one store and apply the results to many; and (6) from economies in advertising and sales promotion. Many chains have also been able to lower prices through elimination of superfluous services. On the other hand, the chains have suffered from a lack of flexibility in adjusting to local conditions and from the increasing costs of their own bureaucratic administration. Discriminatory tax and licensing regulations, imposed particularly during the years between World Wars I and II, hampered chain store development, especially in some European countries, and, to a lesser extent, in some U.S. states. Considerable concentration characterized the U.S. chain store movement after World War II, with many smaller chains being merged into larger organizations and with many chains using one large store to replace several smaller units. Chains operating ten or more establishments do from 20% to 25% of total retail business in both the U.S. and Great Britain, and are particularly important in the distribution of highly standardized commodities that consumers purchase repetitively, such as grocery products. Independent retailers in many countries countered the competition of the chains in part through the successful formation of voluntary or co-operative chains (which should be clearly distinguished from consumer co-operative stores). These are more or less loose affiliations of independent merchants, often formed under wholesaler sponsorship, to purchase merchandise jointly, to share experience and advice, and to engage in joint advertising and sales promotion. They tend to be heavily concentrated in food retailing.

Supermarkets and Self-Service.—Supermarkets, large stores selling groceries and other products through self-service methods, first gained acceptance in the U.S. during the great depression of

the 1930s. Although low prices seemed to be their principal attraction at first, customers apparently liked the large assortments these stores offered and the opportunities for inspecting and selecting merchandise without the unwelcome attentions of salesclerks. The success of the early supermarkets led to the adoption of self-service techniques in all large-scale food retailing in the U.S., and also, but much less extensively, in hardware, variety and drug stores, and in some department store divisions. Self-service stores spread rapidly in Europe after 1954 and by the early 1960s they accounted for 25% of all food sales in Germany and the Netherlands.

Self-service has required the creation of open display fixtures that allow the customer to inspect and handle the merchandise. The package, rather than the salesclerk's persuasion, is the principal selling factor under self-service. This has encouraged improvements in packaging materials and design, has fostered standardization of goods, and undoubtedly has contributed to the growth of well-advertised manufacturers' brands, which the consumer will accept upon sight.

Resale Price Maintenance.—Differences in costs and in price policies among retailers handling the same commodities can lead to intensive price competition. Retailers in many countries have sought legislation that would limit such competition through licensing and tax restrictions on vigorous competitors, such as chains and co-operatives; through laws against "loss leader selling," *i.e.*, retailing some items below cost to attract trade; and through resale price maintenance, an arrangement whereby manufacturers specify the prices at which merchants must resell their products. Some manufacturers have felt that such control helps protect the reputation of their products, but small retailers, who call such arrangements "fair trade," have been the most ardent advocates of price maintenance. Such arrangements were generally considered illegal restraints of trade in the U.S. until the federal Miller-Tydings Act (1937) permitted the states to authorize price maintenance on goods moving in interstate commerce. Permissive statutes, adopted in 45 states, were generally sustained in the courts until about 1950, but during the next decade they were upheld in some jurisdictions and limited in others, in spite of additional supporting federal legislation (McGuire act, 1952). British (1956) and German (1957) acts outlawed agreements among manufacturers for collective enforcement of resale prices, but both sanctioned resale price maintenance by individual suppliers. Legislation has made resale price maintenance generally illegal in Canada, France, Sweden, Denmark and Norway, though in some of these countries provision is made for exemptions in special cases (*see* FAIR TRADE LAWS).

Discount Houses.—Discount house (*q.v.*) is a vague term that originally denoted certain relatively small retail firms in the U.S. that operated in inconspicuous locations; made either some pretense or some attempt at restricting patronage to favoured groups such as civil servants; offered limited services; and sold electrical appliances, jewelry, luggage, sporting goods and perhaps furniture for considerably less than the going price. Legalization of resale price maintenance, which was mainly enforced in more conspicuous stores, gave consumers standards for judging discount values and undoubtedly helped foster discount house growth in the later 1930s and after World War II. Increased public attention to this growth in turn contributed to the legal and economic attacks on resale price maintenance after 1950. The discount houses eventually adopted many of the attributes of conventional retailing, and many firms developed chains of large, highly conspicuous, low-margin, self-service general merchandise stores. This growth provoked retaliatory competition and partial adoption of discount retailing techniques in many department stores.

Current Trends.—General long-run increases in over-all productivity and consumer living standards suggest further increases in retail sales volume, employment and services. Tendencies towards urbanization that provide highly concentrated markets are favoring large-scale retailers. Planned suburban shopping centres are also fostered by urbanization. New methods of stock control, using mechanical and electronic computers for statistical analysis of merchandise receipts, sales and requirements, are beginning to help the large firms increase turnover rates and reduce expenses. At the same time, rising standards of living and increased consumer desires for luxury and convenience provide new opportunities for small retailers who can offer specialized or differentiated services. *See* CHAIN STORE; CO-OPERATIVES; DEPARTMENT STORE; MAIL-ORDER BUSINESS; *see* also references under "Retailing" in the Index.

RETALHULEU, a department in southwestern Guatemala on the Pacific lowland. Area 717 sq.mi.; pop. (1964) 122,829. Coffee is grown on the slopes of the highlands at the northern end of the department. In the lowlands at the base of the highlands there are plantations of sugar cane, cotton, rice, and cacao. Much land is devoted to the feeding of beef cattle. Retalhuleu, the departmental capital, is served by rail and highway. A railroad connects with the port of Champerico. (P. E. J.)

RETARDED CHILDREN. The phrase "retarded child" means one whose rate of development has been in any way slower than average. The retardation may involve physical, mental, educational, or emotional development. With earlier psychological writers, however, the phrase, when used without further qualification, usually refers to backwardness in general intelligence. In studying mental defectives in Paris, Alfred Binet noticed that in their intellectual processes they commonly resembled children three or four years younger than themselves and inferred that their condition resulted from the fact that their rate of mental growth had been retarded from birth onward. Accordingly, he suggested that a child's level of intelligence might be measured in terms of a mental age, with the difference between mental age and chronological age indicating the severity of the retardation. However, a backwardness of (say) two years would mean very different things at the age of 5 and 15; and a baby of 12 months could not be retarded by that amount. Later investigations showed that, in point of fact, the range of individual variation increases from birth to puberty in rough proportion with chronological age. Hence, it was suggested that instead of taking the difference between the mental and chronological ages it would be better to take the quotient or ratio. Expressed as a percentage, the index so obtained is known as a mental ratio or (more frequently) an intelligence quotient (IQ).

Later writers use the term retarded child in a broader sense to include all those whose educational progress, from whatever cause, has been slower than that of an average child of the same chronological age. This is the definition suggested by the (British) Joint Committee on Mental Deficiency. Since the passing of the Education Act of 1944, however, the designation more frequently adopted in British official publications is "educationally subnormal." Occasionally the child's educational age is compared not with his chronological but with his mental age. In such cases an educational or achievement quotient is taken as the measure. With this interpretation a child whose tested intelligence was well above average would still be called retarded if his attainments in the chief school subjects were no more than those of the child whose intelligence was average for his age. There are many children who in their emotional behaviour show the impulsiveness, the lack of control, and the general modes of reaction distinctive of children several years younger: such children are often described as emotionally retarded, though here the term emotionally immature is more commonly employed. Finally, when a child's physical characteristics—height, weight, proportions, teeth, pubertal manifestations—are those of a younger child, he is sometimes described as physically retarded. Generally all types of retardation tend to go together.

Borderlines.—Since retardation is necessarily a matter of degree, the line between the retarded and the nonretarded must be a matter of convenience and convention. A pupil whose educational level is equivalent to that of children in the class below that which would be normal for his years needs no special treatment. Thus a child of 10, if normal, would be placed in a class containing children whose ages ranged from 9.5 to 10.5 years.

Those in the class below would range in age from 8.5 to 9.5 years. If the pupil is unable to do the work even of these younger children, then, as experience shows, he requires education in a specially organized class with those who are equally subnormal. This implies that at a chronological age of 10 the borderline should be drawn at an educational age of 8.5 or generally at an educational ratio of 85%, which is the line of demarcation usually adopted for administrative purposes.

In the case of so-called mental retardation (*i.e.*, retardation in tested intelligence) the upper borderline is similar. But a further classification is plainly desirable. The main division—between the milder cases and the more severe—is usually placed at an IQ of about 70. The figure is chosen because pupils below this level need educational provision in a special type of school. In the United Kingdom, before the Education Act of 1944, they had to be certified as mentally defective before they could be removed to such a school. The act abolished the need for certification and, provided the children are in some degree educable, for official purposes they are classed with the "merely dull or backward" as belonging to the educationally subnormal, though psychiatrists retain the older nomenclature.

In the United States children whose IQ falls below 70 are sometimes termed feebleminded.

Causes.—Educational retardation is due to a wide variety of conditions, and in most instances several factors contribute, although one usually stands out as the major cause. The commoner factors may be divided into two groups: extrinsic or environmental, and intrinsic or personal.

Among environmental causes statistical surveys show that home conditions are more significant than school conditions. Among the lower classes poverty, together with all the handicaps it brings in its train, is one of the most frequently reported. In Western countries, however, its influence has steadily diminished. The cultural conditions of the home—a low intellectual level or a lack of educative interests among the parents—appear far more important. But even in a comfortable and cultured home emotional disturbances within the family may at times so upset the child as to affect his work in the classroom. Of conditions more closely connected with the school, irregular attendance is the commonest. Almost equally frequent are inadequate organization of the classes, and inefficient or inappropriate methods of teaching.

Of conditions obtaining within the child himself, physical defects are less important than is popularly supposed; ill health forms a major factor in only about 10% of the cases. Innate inferiority of general intelligence occurs in well over three-quarters of the cases, and in about one-half it constitutes the major cause. Of more specific disabilities the most obvious are uncorrected defects in sight and hearing. More easily missed are defects in visual and auditory perception or imagery: some children are lacking in verbal facility, others in numerical ability, but by far the commonest defect is in mechanical memory. Temperamental conditions, notably emotional instability, are found among about 7%, often conjoined with motivational problems: the child is lazy and ill disciplined in the classroom and prone to petty delinquencies in his life out of school.

Education and Treatment.—The first step is to ascertain the cause of retardation. Where educational retardation is due primarily to basic weakness in general intelligence, it is to that extent irremediable, but much may be done by suitable training in a special school or institution. With milder cases, reclassification for specific subjects, individual coaching, attendance at a special centre (*e.g.*, for speech training), or transfer to a special class may be advised. In the investigation and treatment of special disabilities, assistance commonly is needed from an educational psychologist or child guidance clinic. (Cy. B.)

Historically, scientific attempts to educate mentally retarded children began with the efforts of a French doctor, Jean Marc Gaspard Itard, during the latter part of the 18th century. In his classic book, *The Wild Boy of Aveyron* (1801), Itard related his five-year effort to train and educate an 11-year-old boy found running naked and wild in the woods of Aveyron. Later Édouard Séguin, a student of Itard's, devised an educational method using physical and sensory activities to develop mental processes. Séguin's published works (1846 and 1866) influenced Maria Montessori (*q.v.*), an Italian pediatrician who became an educator and the innovator of a unique method of training young mentally retarded children in Rome in the 1890s. Later she applied these methods to young normal children. Self-education through the use of specially designed "didactic materials" for sensorimotor training was the keynote of the system (*see* also PRE-ELEMENTARY EDUCATION: *History*).

In the United States the education of the mentally retarded was initiated in an institutional setting by Samuel Gridley Howe during the middle of the 19th century. Institutions for the training of the mentally retarded were then organized in all states. The first public-school special class was established in 1896.

Following World War II the demand for educational services for the retarded became more intense. Enrollment in special classes for the mentally retarded in the United States increased steadily from 87,000 in 1948 to an estimated 350,000 in the 1960s, but this provided education for only approximately one-third of the retarded needing such services.

In other countries there has also been a doubling and tripling of classes for mentally retarded children. A United Nations report (1960) compared programs throughout the world. This report indicated that where provisions were made, one-fifth to one-third of the retarded children were receiving special education. The others were either not in school or were in regular classes. Countries with low economic development usually had few special classes or none. Concentration of special classes in urban areas was common. In some countries, as in the Soviet Union, the problem of providing for rural children was solved by the establishment of boarding schools.

The organization of special classes follows different patterns in different localities. In the United States the pattern is, with few exceptions, to establish special classes in the regular school, with private boarding schools available for some. In some other countries special day schools enroll only retarded children. A third type of organization is the publicly operated boarding school for the retarded. This plan, as mentioned above, is appropriate for rural children. In many countries a combination of facilities is provided.

There has been a growing tendency, especially in the United States, to use the term "exceptional children" to designate those atypical children who deviate from the ordinary child in physical, social, or intellectual traits to such an extent that they require special educational provisions in special schools and classes. Mentally retarded children are usually classified educationally as either "educable" or "trainable." The educable retarded child is one whose IQ ranges between 50 and 75, and who is capable of attaining minimum literacy standards and supporting himself, partially or totally, at the adult level. The trainable retarded child is one whose IQ ranges between 30 and 50, and who is not expected to attain minimum literacy standards but who can be trained for self-help, social adjustment, and economic usefulness in the home or a sheltered environment.

The trainable mentally retarded have been providing an increasingly large proportion of those enrolled in state residential schools, while the educable are being served more and more in special day-school classes. However, community classes for the trainable are also on the increase under the auspices of health authorities, public-school systems, or social welfare departments. Programs for the educable retarded are under the auspices of educational authorities.

The cost of educating a mentally retarded child is twice that of educating an ordinary child. As a rule the education of a mentally retarded child is free when under public auspices; private boarding schools charge fees depending on the type of care and services provided.

The special education of the mentally retarded in special schools and classes is characterized by a number of features. The class size is generally limited to 10 or 15 so that more individualized instruction is possible. The curriculum is similar to that of the regular classes except that academic instruction begins at a later

age with readiness experiences being extended to the age of 8 or 9, since these children are developing mentally at approximately one-half to three-fourths the rate of a normal child. These children may acquire functional literacy at about a third- to fifth-grade level by the age of 16. Materials are presented more gradually and more concretely with more repetition and practice (*see* also READING). Much emphasis is given to social adjustment, to interpersonal relations, and at older ages to occupational education.

There was a paucity of research relative to the education of the mentally retarded until after 1950, since few educational researchers were attracted to the area before that time. Since that date research programs have been initiated primarily in the U.S., in England, and in the U.S.S.R. In the U.S. the Institute for Research on Exceptional Children was organized at the University of Illinois in 1952, and later, centres were established at George Peabody College for Teachers, Nashville, Tenn., and at Syracuse University. In England research was initiated at Maudsley, Manor, and Fountain hospitals. In the U.S.S.R. research has been conducted at the Institute of Defectology in Moscow.

Research and the training of professional personnel were stimulated internationally by the interest of the Joseph P. Kennedy Jr. Foundation and in the U.S. by Pres. John F. Kennedy. Kennedy's sponsorship of federal legislation resulted in the organization and expansion of programs for the training of teachers and other professional personnel in this field and for the establishment of research centres for the mentally retarded, affiliated with universities.

RETFORD (officially EAST RETFORD), a market town and municipal borough in the Bassetlaw parliamentary division of Nottinghamshire, Eng., 30 mi. NNE of Nottingham by road. Pop. (1961) 17,792. Area 7.3 sq.mi. (18.9 sq.km.). Retford (Redforde in Domesday Book) owes its beginnings to its position near one of the Roman roads and on the River Idle, where there was a ford. In 1086 the archbishop of York owned a mill at Retford. It was a borough by prescription.

The earliest charter in the possession of the corporation is that of Edward II (1313), but charters were granted by Henry III (1246) and Edward I (1276). Other charters which have survived are those of Edward III (1329), Richard II (1378), Henry IV (1401), Elizabeth I (1562), and James I (1607). East Retford returned two members to parliament from 1315 to 1330 and again from 1571 to 1830. The borough was joined with the hundred of Bassetlaw and two members were returned until 1885 when the representation was reduced to one member.

The town has flourishing markets and engineering, rubber, wire, and dyeing and cleaning works, iron foundries, and paper and grain mills. Coal is mined in the vicinity.

RETHEL, ALFRED (1816–1859), one of the few exponents of monumental painting and historical subjects of 19th-century Germany, was born at Aix-la-Chapelle (Aachen) on May 15, 1816. At 13 he entered the Düsseldorf academy, which was at that time flourishing under the direction of Wilhelm von Schadow-Godenhaus. In 1836 he moved to Frankfurt (where artistic life centred around Philipp Veit) and was selected to decorate the walls of the imperial hall in the Römer palace with figures of famous men. Four years later he was commissioned to ornament the restored council house of Aix-la-Chapelle with frescoes from the life of Charlemagne, but the execution of this work was delayed for about six years. Meanwhile, Rethel occupied himself with the production of easel pictures and drawings. In 1842 he began a striking series of designs in which the weird power that animates his later art became apparent. In 1844 he visited Rome, executing among other works his famous cycle "Hannibal Crossing the Alps." Returning to Aix in 1846, he began the Charlemagne frescoes. But he was now showing the first signs of mental derangement. Hovering between madness and sanity, he produced during this period some of his most impressive works. He died at Düsseldorf on Dec. 1, 1859.

His assistant Joseph Kehren continued Rethel's work on the half-finished series of the Charlemagne frescoes, and five of the original eight frescoes survive. Rethel is best known for his powerful series of woodcuts entitled "The Dance of Death," suggested by the Belgian insurrections of 1848, and two woodcuts, "Death as Friend" and "Death as Foe."

RETIEF, PIET (1780–1838), ablest of the leaders in the Great Trek, the migration of certain South African Boers to become independent of British rule, was born in the western Cape Colony on Nov. 12, 1780. Better educated than other trekker leaders, Retief enjoyed a varied business and farming career. From 1814 he lived near the eastern frontier of the Cape Colony, where he was a field commandant and achieved some prominence by publicizing the grievances of the frontier Boers. Having decided to trek, Retief in February 1837 published his manifesto on behalf of the emigrant Boers, explaining their motives for trekking. He joined other trekkers north of the Orange River and, being the only leader acceptable to all parties, was elected governor and head commandant of the trekker community (April 1837). His immediate aims were to maintain unity among the trekkers and to lead them to Natal, in his view the trekkers' promised land. After descending the Drakensberg into Natal (October 1837) he visited the kraal of the Zulu king Dingaan to negotiate the cession of Natal to the Boers. During a second visit, on Feb. 6, 1838, Retief and his party, having obtained their treaty, were massacred by Dingaan's warriors. Their remains were found in December 1838, after the Boer victory over Dingaan at Blood River. *See* further CAPE OF GOOD HOPE: *History: British Colonization and the Great Trek;* NATAL: *History: The Voortrekkers in Natal.*

See G. S. Preller, *Piet Retief* (1920). (N. G. GA).

RETREAT, in religion, a period of withdrawal from the ordinary activities of daily life in order to meditate on the central truths of faith and to seek closer union with God through prayer and the ordering of one's life according to the divine will. Retreats are made by individuals or groups, under the guidance of a spiritual director, in premises set aside for the purpose, and in silence.

The general practice of retiring into solitude for prayer and meditation has always existed in Christianity; from the beginning, serious souls, stimulated by the example of Christ's 40 days in the desert, have found in it an effective means of regaining spiritual perspective and strength for life in a complex and demanding world. The late 16th century saw the rise of a definite movement in the Roman Catholic Church toward organized retreats for both clergy and laity. The movement has grown steadily. St. Ignatius Loyola's (*q.v.*) *Spiritual Exercises* not only gave the initial impetus to the movement but also provided a carefully worked out pattern of matter and method which has left its permanent mark on Christian spirituality. While the worldwide spread of retreats has been a movement predominantly within the Roman Catholic Church, retreats have also played a notable part in the practice of the Anglican Church since 1856.

In the 20th century the most noteworthy development has been the spread of retreats for the laity. The commonest form of these exercises is the weekend retreat of two or three days, sometimes extended to five or more days, as is customary in retreats for the clergy. (C. G. McM.)

RETZ, JEAN FRANÇOIS PAUL DE GONDI, CARDINAL DE (1613–1679), French prelate, the agitator and theoretician of the Fronde (*q.v.*), and a writer of extraordinary genius. He was born at Montmirail in September 1613, the third son of the devout Philippe Emmanuel de Gondi. Of Florentine origin, the Gondi family moved to France early in the 16th century and rapidly accumulated honours, including the duchy of Retz. To

enable him to succeed his uncle, Jean François de Gondi, as archbishop of Paris, the young Jean François Paul was educated for an ecclesiastical career, much against his own will. By his duels and his love affairs he sought to demonstrate his worldliness. Politically he sympathized with the opposition to the cardinal de Richelieu (*q.v.*). His manuscript *La Conjuration de comte Jean Louis de Fiesque,* written *c.* 1632, ostensibly about the Genoese G. L. Fieschi, was a defense of revolution as a path to "glory."

In 1643 the queen regent of France, Anne (*q.v.*) of Austria, nominated Gondi as co-adjutor (that is, acting deputy and successor designate) to his uncle. Without reforming his private life, he set himself to raise the prestige of the archbishopric.

The article FRONDE provides an account of Gondi's role in the troubles of 1648–52. Any hopes that he had of supplanting Cardinal Mazarin (*q.v.*) in the royal council came to nothing; but his audacity and his political acumen made him a force with which both the government and the factious princes had to reckon. Anne reluctantly tried to buy his covert goodwill by nominating him for a cardinalate (Sept. 22, 1651); and before she could revoke the nomination his agents in Rome induced Pope Innocent X to give effect to it (Feb. 19, 1652), whereupon Gondi took the style of cardinal de Retz (or Rais). Among the Parisians, however, as his dealings with the government became obvious, he lost much of his popularity; and the government, which he had by turns defied, blackmailed, and outwitted, was waiting for revenge.

On Dec. 19, 1652, Retz was arrested and taken to Vincennes. The government now pressed him to resign his post of co-adjutor. While Pope Innocent X remonstrated on his behalf, Retz took secret measures so that his proxy was canonically installed as administrator of the diocese an hour after his uncle's death (March 21, 1654), before the government could intervene. A few days later, Retz agreed to resign. Pending the pope's assent, he was transferred to easier custody at Nantes. The pope withheld assent.

Fearing strict confinement again, Retz escaped from prison (Aug. 8, 1654). With his shoulder dislocated by a fall from a horse, he took shelter with embarrassed relatives in the Retz country before making his way in a small boat to Spain. The Spaniards conveyed him with honour to Italy, and he went on to Rome.

Innocent X died on Jan. 7, 1655. His successor, Alexander VII, did not want to quarrel forever with France about the archbishopric which Retz now reclaimed as having been extorted under duress. Retz left Italy in summer 1655 and spent a year in obscure movements along the Franco-German frontier. Later, apart from two visits to England (1660 and 1661), he was in the Netherlands. After Mazarin's death (March 1661), he at last agreed to resign Paris in exchange for the abbacy of Saint-Denis and a substantial income (Feb. 14, 1662).

Abhorred by Louis XIV, Retz spent his last years at Commercy or in his French abbeys, though he went to Rome on a diplomatic mission (1665) and for conclaves (1667, 1670, 1676). From 1675 he lived in penitence. He died in Paris on Aug. 24, 1679.

Retz's *Mémoires,* first published in 1717, constitute one of the great masterpieces of French prose. The first part is fragmentary, the manuscript having been mutilated, perhaps by way of expurgation; the second part covers the Fronde, the imprisonment, and the escape to Italy; the third part stops abruptly during Retz's dealings with Alexander. If Retz embellishes his own political activity, he gives an incomparable panorama of events and personalities. Frank about his private morals, he writes without bitterness toward enemies or vacillating colleagues, as if his vivid "portraits" of them were judgment enough. The style, uninhibited by the later rules of "classicism," fluctuates between rapid passages of narrative, marked by aristocratic wit and spontaneity, and elaborately constructed "periods" of political dialectic.

Retz's *Oeuvres,* in the best edition (1870–1920), fill 11 volumes in the series *Grands Écrivains de France.* The second of the *Pléiade* editions (1956) contains valuable appendices.

See L. Batiffol, *Biographie du cardinal de Retz* (1929); Albert-Buisson, *Le Cardinal de Retz* (1954). (J. G. R.-S.)

RETZIUS, ANDERS ADOLF (1796–1860), Swedish anthropologist and anatomist, the best-known member of a distinguished family of scientists, was born at Lund on Oct. 13, 1796. He was the son of the chemist and naturalist ANDERS JAHAN RETZIUS (1742–1821), who was professor of natural history at the University of Lund and who later taught economics and chemistry there. The evergreen shrub *Retzia* is named for him. A brother, MAGNUS CHRISTIAN RETZIUS (1795–1871), became professor of obstetrics in the Carolinian Institute, Stockholm, and director of various lying-in hospitals there.

Anders Adolf received his medical education at the universities of Lund and Copenhagen and the Carolinian Institute, and subsequently held professorships of anatomy and physiology in Stockholm. During trips abroad he met the Czech physiologist J. E. Purkinje, Johannes Müller of Berlin, and other medical scientists with whom he collaborated. Retzius is best remembered for his pioneering work in craniometry (the measurement of skulls as a means of establishing racial characteristics). Named for him are a number of anatomical structures including the gyri of Retzius (convolutions in the brain) and the ligament of Retzius (in the ankle). He died on April 18, 1860. His brother CARL GUSTAF RETZIUS (1798–1833), a chemist, taught at the University of Lund and the Stockholm veterinary school. Anders Adolf's son, GUSTAF MAGNUS RETZIUS (1842–1919), an anatomist and anthropologist, is best known for his studies on the histology of the nervous system. (HD. ST.; X.)

REUBEN (in the Douai Version of the Bible, RUBEN), the eldest son of Jacob by his first wife, Leah (Gen. 29:32), and the eponymous ancestor of one of the 12 tribes of Israel. For reasons that are obscure it lost its position as the foremost tribe at an early period of history. The territory east of the Dead Sea which later tradition assigns to it is not clearly delimited or distinguished from the territories of Gad and Moab, into which it was probably merged quite early. *See* TWELVE TRIBES OF ISRAEL.

REUCHLIN, JOHANN (1455–1522), German humanist, second only to his younger contemporary Desiderius Erasmus. Jews and Protestants have cause to remember him, for he prevented the destruction of Jewish books and, by awakening the forces of liberalism and bringing about a decline in the power and esteem of the Dominicans, enhanced the possibility of success for the Reformation. Reuchlin was born on Feb. 22, 1455, at Pforzheim in the Black Forest. He studied at Freiburg, Paris, Basel, and again in Paris, specializing in Greek. Returning to Basel, he took his master's degree (1477) and began to lecture, teaching a more classical Latin than was then common in German schools and also explaining Aristotle in Greek. During this period he published a Latin lexicon (*Vocabularius Breviloquus;* 1st ed., 1475–76). After further study at Paris he switched from the classics and studied law at Orléans and at Poitiers, taking his degree as licentiate in 1481.

On his return to Germany Reuchlin was engaged as interpreter by Count Eberhard of Württemberg for a tour in Italy beginning in February 1482. His connection with the count became permanent, and he was given important posts at Eberhard's court in Stuttgart and also practised law in the city. Though he appears to have married at about this time, little is known of his married life. He left no children, though in later years his sister's grandson Philipp Melanchthon was almost as a son to him, till the Reformation estranged them.

In 1490 Reuchlin was again in Italy, where he saw Pico della Mirandola (*q.v.*), to whose cabalistic doctrines he afterward became heir. His mystico-cabalist ideas were expounded in the *De Verbo Mirifico* (1494) and in the *De Arte Cabbalistica* (1517). Interest in Cabala led him to interest in the Hebrew language, and on an embassy to Linz in 1492 he began to read Hebrew with the emperor Frederick's Jewish physician. Eberhard of Württemberg died in 1496, and Reuchlin, out of favour with his successor, went to Heidelberg as counselor to Elector Philip of the Palatinate and as tutor of the elector's sons. In this court of letters Reuchlin made translations from the Greek and wrote two Latin comedies in imitation of Terence. Philip sent him in 1498 on a mission to Rome, from which he returned laden with Hebrew books. In 1499 he was able to go back to Stuttgart, where he was given high judicial office which he held till 1512, when he retired to a small estate near the city.

For many years Reuchlin had been increasingly absorbed in Hebrew studies. In 1506 there appeared his epoch-making *De Rudimentis Hebraicis*—grammar and lexicon—mainly based on David Kimchi (*see* KIMCHI) yet by no means a mere copy of another man's teaching. This work was of the first importance in promoting the scientific study of Hebrew and hence of the Old Testament in its original language. Six years later Reuchlin published an edition of the seven penitential psalms (6, 32, 38, 51, 102, 130, and 143) in Hebrew with a Latin translation.

It was Reuchlin's work in Hebrew that led to his celebrated quarrel with the converted Jew Johann Pfefferkorn and the Dominicans of Cologne, a European *cause célèbre* that has been called the culminating point of humanism. It was the view of many of Reuchlin's contemporaries that the first step toward the conversion of the Jews must be to destroy their books, especially the Talmud. To such action Reuchlin, for reasons of scholarship, was strongly opposed. Pfefferkorn succeeded in getting from the emperor Maximilian authority to confiscate all Jewish books directed against the Christian faith, and thus armed he visited Stuttgart and asked Reuchlin's help as a jurist in putting the plan into execution. Reuchlin evaded. In 1511 Pfefferkorn circulated a gross libel (*Handspiegel wider und gegen die Juden*) declaring that Reuchlin had been bribed to favour Hebrew studies at the universities. Reuchlin retorted as warmly in the *Augenspiegel* (1511). When this was confiscated he met his foes with open defiance in a *Defensio contra Calumniatores* (1513). The universities were now appealed to for opinions, and all, even Paris, decided against Reuchlin. Formal inquisitorial processes were started against him at Mainz by the Dominican inquisitor Jakob Hochstraten on Sept. 15, 1513. Reuchlin would have been condemned and his book burned had not the archbishop of Mainz intervened with a letter declaring any judgment null and void. All Germany rejoiced over the discomfiture of the Dominicans.

Reuchlin had appealed to Pope Leo X, who referred the matter to the bishop of Speyer. The latter delegated it to two representatives, who condemned Hochstraten and imposed silence on him. But the Dominican had appealed in advance to the pope, and Reuchlin had to send his papers to Rome. His request for settlement was supported by the emperor, various electors, and 53 Swabian towns. The Cologne group published the opinions of the universities favourable to their side.

The pope entrusted the case to the learned Cardinal Grimani, who summoned Hochstraten to Rome; he arrived well supplied with gold. The pope had ordered that the court be expanded to a commission of 18 prelates. When these showed an inclination to favour Reuchlin, the Dominicans threatened to call a council in the event of an unfavourable verdict. Pfefferkorn continued his agitation.

Reuchlin, though retired from office, kept his courage and was cheered by the sympathy of enlightened men. In 1514 he published a collection of supporting letters he had received, *Epistolae clarorum virorum* ("Letters of Famous Men"). It now became a mark of intelligence to belong to the Reuchlinists; a whole liberal party seemed to spring into being against the reactionaries.

On July 2, 1516, the prelates, with only one dissenting vote, gave their verdict in favour of Reuchlin. Though Leo X, fearing the powerful Dominican order, issued a mandate quashing the entire dispute, in effect the success was still Reuchlin's.

In 1515 there had appeared a work that led all Europe to laugh at the Cologne group—the *Epistolae obscurorum virorum* ("Letters of the Obscurantists"), which mercilessly ridiculed late scholasticism as represented by the "obscurantist" Dominicans. It is believed that Crotus Rubianus was the author, though others may have contributed. So successful were the *Epistolae* that the work was continued (1517) in a further installment, perhaps by Ulrich von Hutten, and found imitation in other writings in the same vein. Interest in the matter was soon displaced, however, by the shift of public attention to Martin Luther and his clash with the church.

The Dominicans of Cologne did not cease to fume against Reuchlin. In the confused situation after the death of the emperor Maximilian (1519), the powerful knight Franz von Sickingen (who later sheltered the Reformers) threatened the Dominicans with reprisals if they did not desist. Eventually terms were reached, and Hochstraten stepped down from his office. The order appealed to Rome for a settlement of the dispute. But very soon it became convenient to blame Reuchlin for the rise of the troubles with Luther, and the Dominicans took advantage of this. Furthermore, many of Reuchlin's former supporters at Rome were dead or no longer at the papal court. The pope now (1520) issued a brief which canceled the Speyer sentence and condemned Reuchlin's book. But the humanist suffered no further persecution.

In 1519 Reuchlin went to Ingolstadt and taught there for a year as professor of Greek and Hebrew. He was then called to Tübingen, where he spent the winter of 1521–22. He died at the baths of Liebenzell on June 30, 1522.

During a great part of his life Reuchlin was the real centre of all Greek teaching as well as of all Hebrew teaching in Germany. Though his stand proved beneficial to the Protestant cause, he himself did not support Luther. He even sought to draw Melanchthon away from Luther and, when he failed, canceled the bequest of his library to his great-nephew.

Blau, *The Christian Interpretation of the Cabala in the Renaissance* (1944). Some interesting details about Reuchlin are given in the autobiography of Conrad Pellicanus (ed. by Riggenbach, 1877). *See* also the article on Reuchlin by G. Kawerau in Herzog-Hauck, *Realenzyklopädie für Protestantische Theologie und Kirche,* 3rd ed. (1896–1913), and literature there cited. (E. G. KR.)

RÉUNION, one of the Mascarene Islands and a French overseas *département* in the western Indian Ocean, lies 425 mi. (680 km.) E of the Malagasy Republic (Madagascar) and 90 mi. (145 km.) WSW of Mauritius. Elliptical in form, it has an area of 969 sq.mi. (2,510 sq.km.). The capital is Saint-Denis (*q.v.*).

Physical Features.—Réunion is entirely volcanic. The oldest erupted rocks belong to the type of the andesites; the newest are varieties of basalts. The main body is a volcanic mass which ceased activity in the Pliocene and is in an advanced state of dissection by short torrential rivers, the chief of which are the Rivières du Mât and des Galets, Bras de Cilaos, and Ravine Sèche. In the west-central area is a mountain massif with three summits exceeding 9,000 ft. (2,740 m.), the Piton des Neiges (10,069 ft.), Le Gros Morne (9,816 ft.), and Grand Bénard (9,501 ft.). Around them are scooped out three wide basins, the Cirque de Cilaos on the south and the Cirque de Salazie and Cirque de Mafatte on the north, draining through narrow gorges down the outer slopes. Around these amphitheatres are a series of plateaus—tablelike facets of the uneroded slopes of the former cones. In the east of the island is an area of about 200 sq.mi. in which vulcanism has been more recently active, and in the extreme east is Le Volcan, one of whose craters, Piton de la Fournaise, was inactive from 1860 until 1925, but has been active several times since then. Le Volcan, exceeding 8,600 ft., and its eastern lava slope, Grand Brûlé, are entirely enclosed within a parabolic mountain wall about 30 mi. long, the whole basin being a huge caldera refilled by recent vulcanism. The massif descends steeply on all sides, but everywhere except on the east it is bordered by a narrow coastal shelf or plain ½–3 mi. in width. The coast consists mainly of cliffs and has no natural harbours.

The climate is dominated by the southeast trade winds during April–October, when the northern and western sides are almost rainless and heavy rain falls in the south and east. Temperatures are cool, especially in the highlands, and snow falls frequently on the Piton des Neiges. In summer Réunion lies within the doldrums, and the lowlands are oppressively humid. Rain falls in all parts, and the island is liable to destructive tropical cyclones. There are appreciable climatic differences according to altitude. Above 2,500 ft. tropical conditions give way to subtropical and temperate conditions. Above 5,000 ft. the climate is cool, with average temperatures around and below 15.5° C (60° F), and with cold nights.

The lowlands formerly carried tropical rain forest, though with a palm savanna on the leeward side. Higher up is a mixed forest with much bamboo, *Casuarina* and *Terminalia*. Above 5,000 ft. a single species, the tamarind, covers a large part of the slopes. Conifers occur above 6,500 ft. and then a subalpine heath. Only about one-fifth of Réunion remains under forest.

The indigenous animal life is not rich in species, many having disappeared. Several bats, wildcats (the tenrec from Madagascar), and rats are the chief mammals. Common birds include the Bourbon flycatcher (*Tchitrea bourbonnensis*), the Mascarene bulbul, the Bourbon manioc bird (*Malacirops borbonicus*), and the introduced cardinal (*Foudia madagascariensis*). There is only one snake (*Lycodon aulicus*).

The People.—Réunion has no indigenous population. When discovered by Europeans it was uninhabited, and no trace of earlier settlement has been found. Present inhabitants include Creoles, Negroes, mulattoes, Chinese, and Indians. Most of the population is descended from slaves and is of African origin, mixed with other elements. A high proportion of the whites live in the highlands, whereas the lowland population is overwhelmingly dark-skinned. Fertility is highest in the lowlands, especially in the capital. Mortality is highest (23–30 per 1,000 in 1950) on the windward coastlands, especially in the towns, and lower in the highlands (10 per 1,000 in La Plaine des Palmistes, at 3,600 ft.). With high fertility and mortality, half the population is under 20 years of age. There is serious overpopulation, and massive emigration has long characterized Réunion. From the early 1950s the main direction of this movement was to Madagascar, where a plan of agricultural colonization by Réunionnais was started. In 1961 the population was 349,282, having doubled in less than a century, and with the elimination of malaria in 1950 the rate of increase steepened. The total includes about 7,000 Asians. Saint-Denis had a population of 65,614 (mun.) in 1961.

The Creole patois is French modified by Malagasy and Bantu pronunciation. French is the official language.

Most of the population is Roman Catholic, exceptions being small numbers of Hindus, Muslims (Indian and Arab), and Chinese. Culture is essentially European, modified by the tropics and by poverty. (Ha. C. Bd.)

History.—Réunion is usually said to have been discovered on Feb. 9, 1513, St. Apollonia's day, by the Portuguese navigator Pedro de Mascarenhas. The island was at first called Santa Apollonia; and the Mascarene Islands, of which Réunion forms a part (the others being Mauritius and Rodrigues), were named for the navigator. François Cauche first hoisted the French flag in 1638, followed five years later by Jacques Pronis, who again took possession of the island in the name of France. Pronis deported from Madagascar to the island 12 mutineers, who, after three years, took back idyllic descriptions of it. Occupation was decided on by Étienne de Flacourt, governor of Madagascar, who gave it the name of Île de Bourbon. In 1662 Louis Payen settled the first colonists, and two years later the Compagnie des Indes Orientales initiated a regular colonization plan. By 1717 there were about 900 free inhabitants and 1,100 Malagasy and Kaffir slaves.

Every colonist was obliged to own at least 200 coffee trees for every Negro working for him. Mocha coffee soon made the island prosperous. Bertrand François Mahé, comte de La Bourdonnais, named governor 1735, developed the fields of rice, grain, and manioc and established the first plantations of sugarcane, indigo, and cotton; sugar soon became the principal crop. In 1764 the company's activities were brought to an end, and the administration of the island was entrusted to a governor, or lieutenant general of the king, and an *intendant* ("administrator"). Spices (Molucca nutmegs and Amboina cloves) were introduced.

In 1793, with the proclamation of the Republic, Bourbon became the island of Réunion. Gen. Charles M. I. Decaen landed in 1803 and began preparations for war in that part of the Indian Ocean, but large numbers of English troops disembarked and in July 1810 the French capitulated. The island was occupied by the English until April 1815, when France again took possession. From then on, Réunion remained at peace. In 1848 the slaves (more than 60,000) were liberated.

In 1946 Réunion became an overseas *département* of France. (Ro. C.)

Administration and Social Conditions.—Réunion, as an overseas *département*, sends three deputies and two senators to the French legislature. Since 1960 the locally elected *conseil général* has had more local autonomy than comparable bodies in metropolitan *départements* have. Technical services are provided by metropolitan ministries, and French legislation and justice extend to the island. Réunion is divided into two *arrondissements*, the Windward (*du vent*) and the Leeward (*sous-le-vent*). The towns are governed by elected municipal councils.

The mass of the population is extremely poor, though wage labourers are generally better off than the peasantry. The white population of the highlands are among the poorest, depending on subsistence cultivation with few economic outlets. The coastal peasantry live almost wholly on rice, the inland on maize (corn). Commerce is largely controlled by a small number of sugar companies. Housing is very poor, with much overcrowding in the towns. There are two technical schools, an agricultural school, and a teachers' training school. Public and private health facilities include seven hospitals and about 80 dispensaries.

The Economy.—The sugar industry dominates the economy, production being concentrated on the coastal lowlands. It was very prosperous up to the mid-19th century but thereafter suffered very heavily through competition from beet sugar in France; improvement was slow. In the 1960s about a dozen big estates and associations with mills were producing the bulk of the crop. The approximately 20,000 small sugar growers are completely dependent on the companies, and their yield is poor. Most of the expansion of sugar production—from 70,000 tons in 1934 to about 248,000 metric tons in 1966—was achieved on the estates. Rum is distilled.

Besides sugar, which represents about 85% of Réunion's exports, the only other important export crops are geranium, vetiver (from which base oils for perfumes are extracted), and vanilla. The vanilla industry developed on the wettest part of the windward coast during the worst of the sugar crisis in the 1870s, but in the 1960s prices and demand were poor, and the industry was declining. Geranium and vetiver production, and to a lesser extent the perfume plants ilang-ilang and patchouli, are concentrated in the highlands, where they developed after the decline of coffee following an invasion of the coffee-leaf disease *Hemileia vastatrix* in the 1880s.

More than 90% of Réunion's exports (mainly sugar and rum) go to France. Imports are mainly manufactured goods (cotton piece goods) from France and foodstuffs (rice), principally from the Malagasy Republic. The currency is the CFA franc, equivalent to 0.02 French francs (CFA Fr. 246.85 = U.S. $1). There are two banks operating in the island.

Communications are good on the coast. A railway skirts the northern and western coasts, and a road encircles the island. Lateral roads give access to the interior, especially to the hill resorts of Cilaos and Salazie. Open roadsteads in front of the main towns (principally Saint-Pierre) were used until the artificial harbour at Pointe des Galets was completed in 1886. All overseas trade is now handled there. A regular shipping service runs to Madagascar and also to France via Suez, and there is a twice-weekly air service to Paris from Gillot airfield near Saint-Denis. Réunion is connected by telephone and telegraph with Mauritius and, via Madagascar, with France. (Ha. C. Bd.)

REUNION, CHURCH: *see* Ecumenical Movement.

REUS, a city of Tarragona province, Catalonia region, northeast Spain, is situated on the coastal plain 8 mi. (13 km.) WNW

of Tarragona by road. Pop. (1960) 41,014 (mun.). In the old part of the town is the Gothic priory church of San Pedro, with its belfry 197 ft. (60 m.) high. Wide avenues surround the city; the modern Avenida de los Mártires has a large obelisk dedicated to those who fell during the civil war. There is much new building, particularly in the Barrio Fortuny on the Carretera de Salou. The city has a municipal museum which includes a prehistoric collection, and numerous educational, cultural, sporting, and recreational centres. Reus has good rail and road connections with Barcelona and Saragossa. Salou beach, a tourist centre on the Mediterranean, is 5½ mi. (9 km.) S. Dried fruit, wine, and oil are exported. Much horticultural produce is grown. Reus is first mentioned in the 13th century, and gained the status of city in the 1840s. It was the birthplace of Gen. Juan Prim (1814–70), of the painter Mariano Fortuny, and of the architect Antonio Gaudí.

REUSS, ÉDOUARD GUILLAUME EUGÈNE (1804–1891), German Protestant biblical scholar, whose works are representative of the painstaking historical scholarship of the 19th century, was born at Strasbourg on July 18, 1804. He studied philology in his native town (1819–22); theology at Göttingen under J. G. Eichhorn; and Oriental languages at Halle under Wilhelm Gesenius and afterward at Paris under the Baron de Sacy (1827–28). He taught at the Protestant Seminary at Strasbourg for 60 years, from 1828 until 1888, and died there on April 15, 1891.

Chief among Reuss's works are: *History of the Sacred Scriptures of the New Testament* (English translation, 1884), which first appeared in 1842 in German and was greatly expanded in later editions; *History of Christian Theology in the Apostolic Age*, two volumes (1852; English translation, 1872–74), a collection of lectures in French; *History of the Canon of the Holy Scriptures in the Christian Church* (1863; English translation, 1884), also in French; and his monumental *Geschichte der heiligen Schriften Alten Testaments* (1881), a veritable encyclopaedia of the history of Israel from its earliest beginning till the taking of Jerusalem by Titus. With A. W. Cunitz and J. W. Baum, and after their deaths alone, he edited the 59-volume edition of John Calvin's works (completed by P. Lobstein and A. Erichsen), which remains the standard edition.

See T. Gerold, *Edward Reuss, 1804–91* (1892).

REUSS, a German dynasty and the states ruled by it. Its lands, in Thuringia (*q.v.*), finally comprised two blocks, separated by part of Saxe-Weimar-Eisenach. The southern and larger block, or Oberland, with Schleiz and Greiz as chief towns, was bounded east by the Kingdom of Saxony, south by Bavaria, west by Saxe-Meiningen and part of Schwarzburg-Rudolstadt, northwest by an exclave of Prussian Saxony. The Unterland, round Gera, was bounded east and west by Saxe-Altenburg, north by Prussian Saxony.

The House of the *Vögte* or imperial advocates of Weida is traceable to the 12th century. All its male descendants have borne the name Henry from the early 13th century, necessitating complex numeration. Its Plauen line was subdivided in 1306 between a senior branch (extinct 1572) and a junior. The latter took the name Reuss from its head, Henry the Russian (so designated, it seems, after marriage with a Russian princess). It became Lutheran and split itself in 1564 into three lines, Elder Reuss, Middle Reuss (extinct 1616), and Younger Reuss.

Elder and Younger Reuss both acquired the rank of count of the Holy Roman Empire in 1673; Elder that of prince in 1778; and the Schleiz, Lobenstein, and Ebersdorf branches of Younger Reuss that of prince in 1806. Both lines entered the Confederation of the Rhine in 1807 and the German Confederation in 1815. Younger Reuss (unified under the Schleiz branch from 1848) joined the North German Confederation in 1866, Elder Reuss in 1867, and both became members of the German Empire in 1871. Elder Reuss had its capital Greiz and other possessions in the Oberland; Younger had the Unterland, with capital Gera, and half the Oberland.

The two territories, which became free states in 1918, merged themselves into a People's State of Reuss on April 4, 1919. This was absorbed into the new Thuringia on May 1, 1920. (FH. H.)

REUTER, ERNST (1889–1953), German political leader, mayor of West Berlin during 1948–53, was born at Aabenraa (Apenrade), in the then German Schleswig, on July 29, 1889. He joined the German Social Democratic Party in 1913 and in 1914 became secretary of the pacifist *Bund Neues Vaterland*. Conscripted into the army in 1915, he was captured by the Russians in the following year. After the Russian Revolution he organized German prisoners of war working at the Tula coal mines. In 1918 he was appointed commissar for the Volga German Autonomous Region, but at the end of the year returned to Germany. Becoming a Communist, he was appointed party secretary for the Berlin area but in 1922 rejoined the Social Democrats. In 1926 he was elected to the Berlin City Assembly. He became mayor of Magdeburg (1931) and was elected to the *Reichstag* (1932). Arrested by the Nazis in 1933, he was allowed to go to England in 1935. He became an adviser at the Ministry of Transport in Ankara, Turkey, and, from 1938, professor of public administration at Ankara University.

He returned to Berlin in 1946 and reorganized the Social Democratic Party. On June 24, 1947, he was elected mayor of Berlin by the city assembly, but was not approved by the Allied *Kommandatura* because of the Soviet veto. When the Social Democrats won a decisive victory in West Berlin on Dec. 5, 1948, however, Reuter was elected mayor; he was reelected in January 1951, although his party had lost its absolute majority in the assembly. A man of courage and an able administrator, Reuter's moral authority extended far beyond Berlin. He died in Berlin on Sept. 29, 1953.

REUTER, FRITZ (1810–1874), German regional novelist, a pioneer of modern Plattdeutsch (north German dialect) literature, and one of its outstanding writers, was born on Nov. 7, 1810, at Stavenhagen in Mecklenburg-Schwerin, where his father was *Bürgermeister*. He studied law at Rostock and Jena. In 1833 he was sentenced to death for alleged high treason as a former member of a student political club; the sentence was commuted to 30 years' imprisonment, but through the intervention of the grand duke of Mecklenburg he was released after 7 years, with his health broken physically and mentally. At first he took up farming, partly to restore his health, but later, encouraged by his wife, Luise Kunze, whom he married in 1850, he settled as a private tutor in Treptow in Pomerania. He lived in Neubrandenburg from 1856 to 1863 when he moved to Eisenach, where he died on July 12, 1874.

The success of his first work, *Läuschen un Rimels* (1853, enlarged 1858), a collection of short stories and rhymes in Plattdeutsch, led him to devote himself to writing in his native dialect. His next work, *Kein Hüsung* (1858), the story of a young couple unable to marry because of a landowner's refusal to give domicile, contains criticism of the feudal conditions then prevailing as well as admirable descriptions of the Mecklenburg landscape. In 1859 he published *Olle Kamellen* ("Old Stories of Bygone Days"), a collection of short stories, the best known of which is *Ut de Franzosentid*, a historical tale presenting with a mixture of humour and seriousness the life of a Mecklenburg country town at the time of the War of Liberation against Napoleon. *Ut mine Festungstid* (1862), an autobiographical novel, gives an account of the last few years of his own imprisonment, written without bitterness or any of his characteristic humour. His masterpiece, upon which his reputation rests, *Ut mine Stromtid*, three volumes (1864), presents a vivid picture of Mecklenburg in the revolutionary period about the middle of the 19th century. Here Reuter displays his masterly ability as a storyteller, as a creator of characters drawn from life (Entspektor Bräsig is one of his best-known characters, as inimitable and immortal as Pickwick), and as the exponent of a peculiarly north German humour. Whereas his contemporary, Klaus Groth (*q.v.*), aimed at raising Plattdeutsch to a literary language, Reuter made his language appear as natural and colloquial as he could. It was he in particular who helped to initiate the development of regional dialect literature in Germany.

REUTER, PAUL JULIUS, Baron von (originally Israel Beer Josaphat) (1816–1899), founder of the first news agency, which still bears his name, was born at Kassel, Ger., on July 21, 1816, of Jewish parentage. He became a Christian in 1844 and adopted the name of Reuter. At 13 he became a clerk in his uncle's bank at Göttingen, where he met K. F. Gauss, who was experimenting with electrotelegraphy. After a period of publishing in Berlin in the 1840s Reuter moved in 1848 to Paris, where he found a growing demand for political news. He began to translate extracts from articles and commercial news and send them to papers all over Germany, but the project collapsed. During 1850 there was a gap between the end of the new German telegraph line at Aachen and the French and Belgian lines at Brussels, and Reuter used 40 pigeons on a service between the two cities. After trying without success to start a news agency in Paris, he moved to England in 1851, later becoming a naturalized British subject. He opened his first telegraphic office near the London stock exchange, and at first his business was practically confined to commercial telegrams. He was not able to persuade the London newspapers to publish his foreign news telegrams until eventually the *Morning Advertiser* agreed to pay him £30 a month for them. Other papers, including the *Times,* fell into line, and the initial telegram of the new service was issued on Oct. 8, 1858. His first great success came early in 1859 when the agency relayed to London a full report of an important speech by Napoleon III to the French legislative chambers. Reuter then extended his service all over the world. In 1861 he laid a special cable from Cork to Crookhaven, Ire., which enabled him to circulate news of the American Civil War several hours before the mail steamers docked. In 1865 he secured concessions for a cable beneath the North Sea to Cuxhaven and another between France and the United States. He was created a baron by the duke of Saxe-Coburg-Gotha in 1871, and 20 years later Queen Victoria gave him and his heirs the privileges of this rank in England. He resigned his position as managing director of Reuter's in 1878, and died at Nice on Feb. 25, 1899.

REUTLINGEN, a town of West Germany in the *Land* (state) of Baden-Württemberg, Federal Republic of Germany, lies on the Echaz River below the Achalm in the Swabian Alps, 40 km. (25 mi.) S of Stuttgart by road. Pop. (1961) 67,407. The most Swabian of all Swabian towns, Reutlingen has half-timbered and gabled tanners' and dyers' houses and 16th-century fountains. The Tübinger Gate and the Garden Gate are remains of the fortifications. The Marienkirche is a fine example of High Gothic (begun in 1247), with a tower erected in 1494. It contains early-14th-century frescoes and an octagonal font of 1499. The economist Friedrich List was born in Reutlingen. In the attractive surroundings are several summer resorts. The chief industry is textile manufacturing and there is a textile technical school with a research institute. Reutlingen was founded by Frederick II between 1236 and 1240, and later became a free imperial city.

REVEL (Reval): *see* Tallinn.

REVELATION, BOOK OF (variously called the Revelation to John, the Revelation of St. John the Divine, and the Apocalypse of St. John the Apostle), last (and the only apocalyptic) book of the New Testament, is a symbolic presentation of the life of the church in a hostile world and a "prophecy" of the final end of all things.

Revelation is one of a group of Jewish and Christian books, called apocalypses, that describes, in elaborate symbols, the victory of God over an evil world. Such other apocalyptic books as Daniel in the Old Testament and II Esdras in the Apocrypha (IV Esdras in the Vulgate), and noncanonical books, such as Enoch and Baruch, as well as many parts of the Dead Sea scrolls from Qumran, provide an indispensable background for understanding the point of view of Revelation. (*See* also Apocalyptic Literature.)

In the apocalyptic view, the world was so decisively alienated from God that its structures of life and power (*e.g.,* structures of politics, economics, prestige, and success) could not be recovered to obedience to God but would have to fall under God's judgment and be destroyed. Though created by God, the world had come under the domination of an evil power—Satan—so that its life was demonically perverted, while human decision and responsibility also contributed to the evil situation of men. In the world, though apart from it, lived a community of believers that was despised and often persecuted by the world but that was yet supported by God in all its trials. In the near future, it was believed, God would overthrow the powers of evil ("this present age"), both in their satanic dimension which pervaded the whole physical and spiritual cosmos, and in their visible political dimension; and then God would establish a new world ("the age to come"). Such a faith is dualistic, since it views life as a struggle between two irreconcilably opposed principles—God and the demonic power of evil (*see* Dualism). But it is not an absolute dualism, for it looks toward the speedy victory of God; and it is not a dualism of body and spirit, for in it evil is a perverted form of selfhood.

Central to the apocalyptic vision is the hope for a perfect community (a "holy city"), in which men will be free to serve God and each other. The failure of the power structures of "this world" to make possible total obedience to God and true community among men is the centre of the world's opposition to God, and the reason why this world must be destroyed to make way for a better one.

The author of Revelation uses a traditional stock of symbols. In particular he draws on the Old Testament, especially Daniel, Ezekiel, and Zechariah. Perhaps ancient astrology supplied some symbols (especially in ch. 12) that came ultimately from Near Eastern creation myths. Jewish and Christian liturgy probably suggested many elements in the book. The author's own visions may have suggested other elements, though as they stand the visions in the book are too carefully integrated with each other and too dependent on tradition to be reports of immediate religious experience.

Since many apocalyptic books present, in symbolic form, a history of the struggles of the faithful, it has often been suggested that the symbols in Revelation represent succeeding historical events. No doubt the actual historical struggles of the church with Roman persecution are reflected in the book, especially in ch. 13 and 17. Nonetheless, the repetitive nature of the images and the lack of concern for strict consistency suggest that the cosmic dimension of the struggle, the conflict of the powers of light and darkness, was more in the author's mind than an ordered series of historical incidents.

Contents.—An outline can only suggest the rich, interwoven texture of the book, which does not have mechanical symmetry but is woven together in complex patterns of threes, sevens, and other numbers. No one outline can claim to be final.

1:1–20	introduction
1:1–3	heading: a revelation of God through Christ
1:4–20	introductory letter: a vision of Christ
2:1–3:22	counsel to the church: the seven letters (varied praise, warning, threat, and promise)
2:1–7	Ephesus
2:8–11	Smyrna
2:12–17	Pergamum
2:18–29	Thyatira
3:1–6	Sardis
3:7–13	Philadelphia
3:14–22	Laodicea
4:1–16:21	the beginnings of Judgment: God's people persecuted; God through Christ protecting his people and destroying his enemies
4:1–5:14	introduction: a vision of God's world; the 24 elders and the Lamb
6:1–8:1	the first cycle of images: the Seven Seals, the first four of which (6:1–8) reveal the "four horsemen of the Apocalypse" (symbolizing the lust for conquest and its inevitable consequences of war, famine, and death; traditionally identified as War, Strife, Famine, and Pestilence) (*interlude* of the setting apart of the faithful and the reward of the faithful in heaven, 7:1–17)
8:2–11:19	the second cycle of images: the Seven Trumpets (*interlude* of the seer, 10:1–11; and the measurement of the temple, 11:1–4; and the witnesses to God's message, 11:4–14)

12:1–15:1	the third cycle of images: the Seven Visions (*interlude?* of the vision of the Lamb and his worshipers, 14:1–5)
15:2–16:21	the fourth cycle of images: the Seven Plagues
17:1–19:10	the Judgment of this world
17:1–18	a woman sitting on a beast; explanation of the seven heads and ten horns of the beast
18:1–24	doom pronounced on "Babylon"; her friends lament her
19:1–10	*interlude:* praise to God for the judgment of Babylon; proclamation of the marriage of the Lamb
19:11–22:5	the final purpose of God
19:11–16	the Word of God riding a white horse
19:17–21	the victory of Christ
20:1–3	the dragon bound for a thousand years
20:4–6	the millennium
20:7–15	the final defeat of Satan and final Judgment
21:1–22:5	the new heaven and new earth
22:6–21	conclusion
22:6–17	concluding words of prophecy: the end is near
22:18–20	warning not to tamper with the book
22:21	benediction

Main Themes.—*Endurance.*—The overarching practical theme of Revelation is a summons to resolute endurance in the face of coming persecution. Courageous loyalty, separation from the evil world, and enduring hope for God's destruction of evil and new creation of a good world are taught through the seven letters, the interludes, the dramatic struggle, and the vision of a new heaven and a new earth.

Cosmic Christ.—The vision of a struggle of cosmic dimensions is paralleled by an understanding of Christ as a preexistent, heavenly being, capable of overcoming the most pervasive demonic opposition. Of Christ's earthly life, only his death and resurrection are mentioned, but these events reveal the eternal purpose of God (1:18; 5:9).

God's Presence in an Evil World.—In Revelation, though Christ's triumph still lies in the future, faith in Christ makes it possible for the believer to span the gap between present and future and to participate, even in the midst of suffering, in the joy and peace of God's presence. The "interludes" in the action are thus not an irregularity in the plan of the book but an important means by which the author communicates his faith that the movement of time can be momentarily halted, as the believer participates, by anticipation, in the end.

Roman Empire as Manifestation of Evil.—The concrete manifestation of satanic power is the government under which the author lived, the Roman Empire. Rome is symbolized (though many details are obscure) by the beasts of ch. 13 and by the beast of ch. 17. The seven heads and ten horns (13:1; 17:3 and 9–14) represent (in a way about which there is little agreement) individual rulers of the 1st century A.D. The author's sense of the hopelessness of a constructive appeal to Rome is one reason for his view that in general the powers of evil must be destroyed rather than converted.

The Millennium.—The most controversial element in the Apocalypse is its prediction of a thousand years' rule of Christ on earth. The author looked forward to a real earthly kingdom, of Christ's, to come soon. That he presented it as temporary shows his conviction that this world, even perfected, could not adequately manifest the glory of God. (*See* also MILLENNIUM.)

The New Jerusalem.—The vision of a true community under God, as God's ultimate purpose, is powerfully presented in the symbols of Rev. 21:1–22:5. This vision, here set in an "otherworldly" framework, has also motivated forms of Christian faith which looked for a partial realization of the hope within the structures of this world.

Literary History.—The author is John (1:4); though most apocalyptic works were published under assumed names, this one does not seem to have been. The author regards himself as a prophet (1:3) but does not call himself an apostle. Strong early tradition identified him with the apostle John (*e.g.,* Justin, *c.* A.D. 155). Yet Papias (*c.* A.D. 140) seems to have reported an early martyrdom for the apostle John, and some early tradition denies the apostle's authorship. Thus while many Roman Catholic and some Protestant scholars support authorship by John the apostle, Protestant scholarship predominantly supports the view that some other John is the author. The differences in language between Revelation and the Gospel of John make it unlikely that the two books come from the same writer. Revelation was written for the churches in the neighbourhood of Ephesus in Asia Minor.

The Apocalypse is usually dated late in the reign of the Roman emperor Domitian (A.D. 81–96) and associated with his persecution of Christians. Since Domitian was the first to insist strongly on divine honours as a living emperor, and since Revelation opposes precisely this form of idolatry (ch. 13), the traditional date is the most probable. Some scholars maintain an earlier date, usually by identifying the sixth head of the beast, which appears to represent the ruling emperor, with an earlier ruler (17:10). But the author may have taken over and reinterpreted the symbolism of the seven heads from an earlier time, or he may have developed it in such a way that it applied to his own time. The symbolic number 666 (13:18) may refer to Nero (A.D. 54–68) but does not necessarily point to composition at the time of Nero or even shortly afterward, since the expectation of Nero's return seems to have been a popular belief even late in the 1st century A.D.

Interpretation.—Older interpretation either "spiritualized" Revelation, applying its symbolism to general truths of the Christian religion, or looked for a literal fulfillment of its prophecies in or shortly after the time of the interpreter himself. Either path may find in the book a source of deep spiritual life but will also lead to misunderstanding of its original meaning, which is better grasped by setting the book in the context of the whole body of apocalyptic literature. Then Revelation is seen as springing from and relating to a crisis in the life of the early church. Its symbols are not descriptions of events in later history.

Once the original setting and meaning of the book are seen, the interpreter must again confront its meaning for his own time. Some students have concluded that the book's lack of hope for "this world" gives it little relevance to the modern world. Others regard its message, originally focused on an ancient crisis, as a valid symbolic representation of the divine purpose. This sort of interpretation may stress the eternal truths of the book, thus standing close to the older spiritual interpretation, and it may emphasize Revelation as a portrayal of the climax of the "sacred history" of God's acts. Then the original situation of conflict with Rome is seen to typify a recurring situation in which the believing community will exist until the final end, when God's will shall be done. Still others would see the contemporary significance of the Book of Revelation in the totality of its claim for obedience, holding that the pictorial vision of the future triumph is of secondary importance and that the call to remain faithful is the enduring message. *See* also BIBLE.

REVENTLOW, CHRISTIAN DITLEV FREDERIK, COUNT (1748–1827), Danish statesman whose agrarian reforms led to the elimination of serfdom in Denmark, was born at Copenhagen on March 11, 1748. He made an extensive tour of Western Europe to study economic conditions before returning to Denmark in 1770. From 1773 he held office in government departments, and in 1775 he inherited the Christianssaede estates in Lolland, where he introduced agrarian reforms and raised his tenants' standard of living. In 1784 he became head of the *Rentekammeret* (Exchequer) which was responsible for agricultural policy. He set up a small agricultural commission to improve the condition of the crown serfs and among other things to enable them to turn their leaseholds into freeholds.

Reventlow induced Crown Prince Frederick (later Frederick VI) to appoint in August 1786 a grand agricultural commission to consider the whole of the peasantry. This resulted in a series of important reforms. The ordinance of June 8, 1787, modified the existing leaseholds, greatly to the advantage of the peasants, and that of June 20, 1788, abolished the so-called *stavnsbaand* of 1733

(the binding of farmers' sons as serfs on the estates where they were born). From 1791 to 1799 voluntary agreements between landowners and tenants considerably modified the *hoveri* system, whereby the tenant had been compelled to cultivate his lord's land as well as his own; and the *hoveri* was clearly defined and regularized by the ordinance of Dec. 6, 1799. Reventlow also started public credit banks enabling small farmers to borrow money on favourable terms.

Denmark's financial distress resulting from its involvement in the Napoleonic Wars (*see* DENMARK: *History*), and Frederick's growing personal rule, prevented Reventlow from completing his reforms. He was dismissed on Dec. 7, 1813, and retired to his estates in Lolland, where he died on Oct. 11, 1827.

REVERE, PAUL (1735–1818), American patriot, craftsman and industrialist, best known for his ride on the night of April 18, 1775, to warn the Massachusetts colonists of the approach of British troops, was born in Boston, Mass., on Jan. 1, 1735. His father Apollos Rivoire (later changed to Revere) was a Huguenot refugee who had come to Boston as a child and had been apprenticed to a silversmith. This craft he taught his son Paul Revere, who became one of America's greatest artists in silver. As a boy Revere received sufficient education to enable him later to read the difficult metallurgical books of his period. When Benjamin Waterhouse was brought to Massachusetts by Harvard college to teach this and allied sciences he thought Revere the only man in America with a competent knowledge in the field. It was in metal that Revere did most of his work. But his energy and skill (and the necessity of supporting an ever growing family) turned him in many directions. He not only made silver but sold spectacles, replaced missing teeth and made surgical instruments. He cut many copper plates, mostly for anti-British propaganda. His "Boston Massacre," in spite of its many inaccuracies, is probably America's most famous print. He took an active interest in politics, was a leader of the Boston Tea Party in 1773 and influenced his fellow artisans toward independence.

With the outbreak of the American Revolution in 1775, Revere was called upon to construct a powder mill to supply the colonial troops. Later he and his sons cast hundreds of church bells, several of them of great beauty. Although he began making copper hardware for ships soon after the Revolution it was not until 1800 that, after considerable experimentation and great expense, he set up in Canton, Mass., a rolling mill for the manufacture of sheet copper. From this factory came the sheathing for many American ships, including the "Constitution," and for the dome of the Massachusetts state house. He worked closely with the inventor Robert Fulton on copper boilers for steamboats. With such ventures he became a connecting link between the medieval craftsman and the modern industrialist.

Revere's military career was undistinguished. In 1776, as a lieutenant colonel, he was in command of Boston harbour's principal defense, Castle William. In 1778 he was sent on the Rhode Island expedition, which proved as complete a failure as the Penobscot campaign a year later. In both of these futile attacks on the British the colonial sea and land forces were unable to work together. The retreat from the Penobscot region became such a scandal that most of the officers involved lost their reputations. Revere's good name was restored several years later after his continual demand for a court martial. Largely because of Longfellow's stirring ballad, he is remembered as the man on horseback who warned Middlesex county on "the 18th of April in '75" that the British troops were leaving Boston to seize military stores at Lexington and Concord. Although not good history the poem is still an impressive memorial to him. For years Revere had been the principal express rider for Boston's Committee of Safety.

By virtue of his title of colonel, his postwar ventures as an importer, the great importance of his copper mill and the fortune he had amassed, he could have referred to himself by several prouder titles than the simple goldsmith or silversmith that he seems to have preferred to his dying day. This attitude J. S. Copley emphasized in the portrait he painted of him shortly before the Revolution, seated at his work bench, in his shirt sleeves. Gilbert Stuart's portrait of him as an old man emphasizes not only his energy but the generosity and kindness that characterized him throughout his long life. Both of these portraits along with the finest collection of his silver are in the Museum of Fine Arts, Boston. The American Antiquarian society possesses the outstanding collection of his engravings.

The house he lived in or owned for about 30 years before his death on May 10, 1818, still stands in Boston's North Square.

See Esther Forbes, *Paul Revere and the World He Lived In* (1942); Clarence S. Brigham, *Paul Revere's Engravings* (1954). (E. FO.)

REVERE, a city and resort in Suffolk County, Mass., U.S., on Massachusetts Bay, 6 mi. (10 km.) NE of Boston. It is the "Coney Island of Boston" with three miles of beach, a dog track, and nightclubs. Almost from its founding (1636) as Rumney Marsh, it was a Boston resort. Subsequently the development of residential suburbs to the north made it turn almost exclusively to its beach front with its roller coaster and numerous concessions.

Because of the extensive marshes the community developed slowly. It was successively a section of Boston, part of Chelsea (1739), and reincorporated as North Chelsea (1846). The latter changed its name in 1871 in honour of Paul Revere. It became a city in 1914. Council-manager government, adopted in 1950, was discontinued by the voters in 1964. Revere is still tied to Boston through the county government. There are large colonies of Russian, Lithuanian, and Italian immigrants and their descendants. The 19th-century Slade Spice Mill is a local point of interest.

Light industry includes electrical equipment, machine parts, chemicals, spices, and beverages. For comparative population figures *see* table in MASSACHUSETTS: *Population*. (R. C. MO.)

REVERSING LAYER. It was formerly believed that the solar continuous spectrum originated in hot lower strata of the sun's atmosphere or photosphere and that the dark line spectrum was all produced in an overlying cooler stratum called the reversing layer, in accordance with Kirchhoff's third law of spectrum analysis. Early eclipse observations, especially that by C. A. Young in 1870, apparently substantiated this picture. Later work showed that the dark line and continuous spectra of the sun or stars were formed in essentially the same layers. Weak spectral lines are formed in the same layers as the continuous spectrum; stronger lines are produced predominantly in higher layers; whereas the centres of the strongest lines are formed in the chromosphere. Although the term has been used occasionally to indicate the upper layers of the photosphere where the strongest spectral lines are predominantly formed, it is now infrequently employed. *See* also SPECTROSCOPY. (L. H. A.)

REVIVALISM in the broadest sense applies to any instance of renewed religious fervour within a group, church or community, whether that group be Christian or non-Christian. However, in common usage it refers primarily to concerted efforts among evangelical churches to revitalize the spiritual ardour of their members and to win new adherents. Revivalism in its modern form can be attributed to that common element in Anabaptism, Puritanism, German pietism and Methodism in the 17th and 18th centuries which stressed personal religious experience (*Herzensreligion*), the priesthood of all believers and holy living, in protest against established church systems which seemed excessively sacramental, sacerdotal and secularistic. Each of these pietistic movements contributed to the revival tradition.

Protesting against the sacramentalism and ritualism of the Church of England, the Puritans who left England carried their fervour for experiential religion and devout living to the new world in 1629. Although this fervour waned toward the end of the century, Jonathan Edwards (*q.v.*) revived Puritan zeal in New England in a period of extraordinary religious excitement from 1734 to 1742. Edwards is sometimes credited with inspiring the first Great Awakening in America (*c.* 1725–50), but this widespread movement of social, theological and ecclesiastical reorientation actually had its beginnings in Europe and reached America in the 1720s through the Dutch Reformed and Presbyterian

churches of New Jersey and the German immigrants in Pennsylvania. While the awakening in New Jersey and Pennsylvania was in part a process of adapting European ecclesiasticism and theology to frontier conditions, it was also closely related to the pietist movement of Philipp Jakob Spener and August Hermann Francke (*qq.v.*) in Germany and to the evangelical revival in England.

Between 1670 and 1730 Spener and Francke had revitalized Lutheranism by forming within the church devout groups of believers who emphasized personal conversion, devotional prayer, asceticism and practical Christian charity. Their influence extended throughout northern Europe, affecting the Reformed churches, the Anabaptists and the revived Moravian church under Count Nikolaus Ludwig von Zinzendorf and August Gottlieb Spangenberg. The Moravian missionaries Spangenberg and Peter Boehler in turn influenced John Wesley (*q.v.*), and his religious conversion in 1738 inaugurated the evangelical revival within the Church of England. Between 1738 and 1791 Wesley traveled throughout the British Isles preaching to large crowds and laying the foundations for what became after his death the Wesleyan Methodist Church. Wesley's preaching emphasized free will and free grace, experiential conversion, the priesthood of all believers, moral perfectionism and philanthropic reform.

His associate George Whitefield (*q.v.*), the founder of Calvinistic Methodism in England, was also influenced by German pietism, and his preaching tours of the American colonies between 1739 and 1770 had a profound effect upon the first Great Awakening in America. Whitefield was welcomed to New Jersey in 1739 by Theodore J. Frelinghuysen, the pietistic leader of the revival among the Dutch Reformed churches; by Frelinghuysen's friend Gilbert Tennent (*q.v.*), the leading revivalist among the Scotch-Irish Presbyterians; and by most of the German-speaking immigrants in the middle colonies. When he toured New England in 1740, Whitefield was also endorsed by Jonathan Edwards and other influential Congregationalists. Throughout America Whitefield's preaching aroused intense religious enthusiasm; however, his emotional mass meetings and the religious disorders aroused by itinerants who imitated his flamboyant methods produced vigorous opposition to the awakening after 1742.

While the first Great Awakening created temporary schisms within almost every denomination in the American colonies, it also stimulated the churches to a vigorous new growth; it paved the way for the separation of church and state; it broke down denominational barriers and helped to unify the colonies; it produced an energetic social and intellectual ferment among the lower classes; and it instituted that emphasis upon religious activism and lay leadership that has since characterized American Protestantism. Like pietism in Germany and Wesleyan evangelicalism in England, the first Great Awakening in America promoted missionary activity, philanthropy, charity and education. Dartmouth college and Princeton and Brown universities were direct outgrowths of this awakening.

Despite the spread of deism during the 18th century the revivalistic impulse continued strong. The evangelical revival flourished in Britain, and at the end of the century a new awakening occurred in America. This second Great Awakening (*c.* 1795–1835) was divided into three phases: The first phase (1795–1810) was associated with the frontier camp meetings conducted by James McGready, John McGree and Barton W. Stone in Kentucky and Tennessee. (*See* CAMP MEETING.) The second and more conservative phase of the awakening (1810–25) centred in the Congregational churches of New England under the leadership of Timothy Dwight, Lyman Beecher, Nathaniel W. Taylor and Asahel Nettleton. The third and final phase (1825–35) stemmed from the activities of Charles Grandison Finney (*q.v.*), who began his revivalism in small towns in western New York in the 1820s but eventually conducted revival meetings in the largest cities in the U.S. and Britain. During the second Great Awakening revivalistic theology in all denominations shifted from Calvinism to Arminianism as preachers emphasized the ability of sinners to make an immediate decision to save their own souls; theological differences almost disappeared among evangelical churches. Moreover, under Finney's aegis a rationale for carefully contrived revival techniques evolved. After 1835 an irregular corps of professional revival experts traveled through the towns and cities of America and Britain organizing annual revival meetings at the invitation of local pastors who wanted to reinvigorate their churches. The second Great Awakening produced a great increase in church membership, made soul winning the primary function of the ministry and stimulated a host of moral and philanthropic reforms including temperance, emancipation and foreign missions. In 1857–58 the famous "prayer meeting revival" swept the cities of the United States following a financial panic. It indirectly instigated a revival in Northern Ireland and England in 1859–61 that rivaled the camp meetings in enthusiasm.

The preaching tour of the American lay evangelist Dwight L. Moody (*q.v.*) and his singing companion Ira D. Sankey through the British Isles in 1873–75 marked the beginning of a new outburst of Anglo-U.S. revivalism. And in his subsequent revival activity in the major cities of Britain and America Moody perfected the highly businesslike techniques that characterized the urban mass evangelistic campaigns of 20th-century professional revivalists such as Reuben A. Torrey (*q.v.*), J. Wilbur Chapman, Gypsy (Rodney) Smith and Billy (William A.) Sunday (*see* SUNDAY, BILLY). The interdenominationally supported revivalism of Moody and his imitators in 1875–1915 constituted in part a conscious co-operative effort by the Protestant churches to alleviate the unrest of urban industrial society by "evangelizing the masses," and in part an unconscious effort to counter the challenge to evangelical orthodoxy brought by higher criticism of the Bible and Darwin's *Origin of Species* (1859). In the first half of the 20th century most educated evangelical churchmen lost interest in revivalism because of its association with fundamentalism (*q.v.*) and turned their attention to social reform. After World War II a renewed interest in mass evangelism appeared, symbolized by the widespread support given to the "revival crusades" of the Southern Baptist evangelist Billy (William F.) Graham (*q.v.*).

Whether mass revivalism has been as helpful to the churches in the long run as its exponents claim is highly debatable, but there is no doubt about its ability to generate at least temporary religious enthusiasm. The best historical explanation for the recurrent nature of revivalism is based upon the inevitable need for theological and ecclesiastical reorientation from generation to generation and the concomitant religious excitement generated by such changes.

(W. G. McL.)

REVUE, a light form of theatrical entertainment, originally deriving from the French street fairs of the Middle Ages, at which events of the year were passed in review in comic song and spectacle. It differs from variety in its use of pointed burlesque and satire, and from musical comedy in having no plot. Revue in its present form, dating from the early 19th century, was first developed at the Théâtre Porte-Saint-Martin in Paris by C. T. and J. H. Cogniard with their *Folies Marigny*. In the 20th century the French revue was the vehicle of such stars as Yvette Guilbert and Maurice Chevalier.

The English revue developed on one hand into a costume display and spectacle, reaching its peak in the Court Theatre productions of the 1890s; and, on the other, intimate shows such as André Charlot Revues of the 1920s in London and the provinces, the handsome shows at the Hippodrome, and especially the performances at Sir Charles Cochran's Ambassadors' Theatre. Revues of the intimate club type played an important part in keeping up the morale of Londoners during the blitz of 1940, both at the

highly regarded Gate Theatre and the famous "Revuedeville" of the Windmill.

In the United States, *The Passing Show,* produced in New York in 1894 (second edition 1911), led the producer Florenz Ziegfeld in 1907 to initiate the 24 annual *Follies,* usually built around a star personality. George White and his *Scandals* put more emphasis on comedians and girls, less on spectacle for its own sake. More modest revues have been the *Music Box Revues,* the *Little Shows* of Dwight Wiman, *The Garrick Gaieties,* the Depression *Pins and Needles* of 1937, and the postwar G.I. show, *Call Me Mister. La Plume de Ma Tante* in 1959–60 returned the revue to its French origins.

REWA, a town, district, and division of Madhya Pradesh, India. The town, formerly capital of the Rewa princely state and now the district headquarters, is situated on a Vindhyan outcrop 980 ft. (300 m.) above sea level and 70 mi. (113 km.) SSW of Allahabad. Pop. (1961) 43,065. It has no rail connection but metaled roads link it with Chhatarpur, Jabalpur, and Allahabad. There are three colleges affiliated with Saugar University.

REWA DISTRICT is roughly triangular in shape and covers an area of 2,509 sq.mi. (6,498 sq.km.) with a population (1961) of 772,602. Many of the inhabitants of the hilly tracts are Gonds and Kols. It is mostly hilly and is cultivated only in shallow depressions covered with laterite soil. Millets, maize (corn), and oilseeds are produced. More than one-third of the total area is under forests, yielding timber and lac. There are valuable coal deposits in the Umaria field.

The history of the former princely state of Rewa was a record of almost continuous warfare until it came under British guarantee in 1812. The ruling family belonged to the Baghela clan of Rajputs, a branch of the Solanki people. (M. N. K.)

REWARD is money or other compensation offered orally or in writing, either by the government or by an individual, to the public generally, or to a particular person or class of persons, for the performance of a designated service, such as the return of lost property or the apprehension of a suspected criminal. The offer expires a reasonable time after it is made, unless it stipulates otherwise. Prior to substantial compliance with the offerer's terms, it may be withdrawn at any time, even if the claimant is unaware of the withdrawal. The offer may contain such terms, provided they are lawful, as the offerer wishes to prescribe. Where a reward is lawfully offered, the first one who satisfies the prescribed conditions is entitled to it. Performance of these conditions constitutes acceptance of the offer and creates a binding contract. If several persons jointly perform the stipulated act, either by concerted action or, according to some authority, by acting independently, the reward may be equitably apportioned among them. Whether a person who is unaware of the offer at the time he performs the requested act may obtain the reward is disputed. One under a moral or official duty to perform the act usually may not claim a reward, unless he was required to perform acts beyond the scope of his duty for the reward. Police officers, therefore, ordinarily may not claim rewards for the apprehension of criminals or the recovery of stolen property, unless a statute provides to the contrary. (RT. K.)

REYKJAVÍK, the capital city of Iceland, is on the northern side of Seltjarnarnes Peninsula on the southeastern corner of Faxaflói (Faxa Bay) in the southwest of Iceland. Pop. (1965 est.) 78,000. Originally on a flat area between the harbour and the small Lake Tjörnin, the town now extends over low hills east and west of the lake. It is on the whole strikingly modern in aspect. Nearly all the houses are built of concrete; most of them are heated by natural hot water from drill holes 1,500–7,000 ft. (460–2,100 m.) deep. Among official buildings are the parliament house, the cathedral, the National Library, the university (founded in 1911), the National Museum, the National Theatre, the state hospital, and the navigation school. Bessastadir, the residence of the president, is outside the town.

Reykjavík is Iceland's main centre of commerce and the location of about half of the country's industrial establishments. The chief industries are food processing, metal and textile manufacture, and printing. Almost one-third of the fish landed in Iceland (apart from herring) is brought ashore there. There are regular shipping services to New York and the principal ports of northern and western Europe; and there are air services from Reykjavík airport (situated within the town) to the United States and many European countries. The international airport at Keflavík is 20 mi. WSW of the city.

Reykjavík ("Bay of Smokes") is situated on the place where the first settler of Iceland, the Norseman Ingólfur Arnarson, took up his abode in about 870. His farmstead derived its name from the smoke of nearby hot springs. A small village grew up there in the 18th century and was granted municipal rights in 1786. Since 1796 it has been the seat of the Icelandic bishop and since 1843 the seat of the Parliament (*althing*). It became the capital of Iceland in 1918; capital of the independent Republic of Iceland in 1944. (S. TH.)

REYMONT (REJMENT), **WLADYSLAW STANISLAW** (1868–1925), Polish novelist and writer of short stories, awarded the Nobel Prize for literature in 1924 for *Chlopi,* a novel of peasant life, was born at Kobiele Wielkie, near Lodz, in central Poland, on May 6, 1868, the son of a village organist. After failing to enter the *Gymnasium,* he became, in turn, a tailor, a wandering actor, a novice in a monastery, and a railway clerk. He began his literary career by writing short stories (published 1893). His account of a pilgrimage to the shrine of the Virgin at the monastery of Jasna Gora in Czestochowa (*Pielgrzymka do Jasnej Gory,* 1895) shows understanding of popular religious feeling. *Ziemia obiecana* (1899; English translation *The Promised Land,* 1927) describes Poles, Germans, and Jews competing ruthlessly for material "milk and honey" in the manufacturing town of Lodz. By contrast, *Chlopi,* four volumes (1904–09; English translation *The Peasants,* 1924–25), presents a panorama of Polish country life. It shows a village in every phase of the recurring cycle of the seasons, and thus, despite the realistic contemporary setting, creates an illusion of timelessness. Each of the numerous characters is endowed with unmistakable individuality. The villagers are the collective hero of this quasi-epic, often lyrical, but seldom idyllic, in tone. Reymont died in Warsaw on Dec. 5, 1925.

See J. Lorentowicz, *Ladislas Reymont, essai sur son oeuvre* (1924); W. Borowy, "Reymont," in *Slavonic Review,* vol. xvi (1937–38). (L. R. LR.)

REYNARD THE FOX, a medieval cycle of animal stories; its main heroes are Reynard the Fox and Isengrim the Wolf. Some of the stories (the wolf, or bear, fishing with his tail through a hole in the ice) are found all over the world; others (the sick lion cured by the wolf's skin) derive by oral transmission from Hellenistic sources. The cycle arose in the Lotharingian area, between Flanders and Germany, in the 10th and 11th centuries, when clerks began to forge Latin epics out of popular tales. The name "Ysengrimus" which appears as a satirical nickname at Laon in 1112 was used as the title of a poem in Latin elegiac couplets by Nivard of Ghent in 1152; some of the stories were soon recounted in French octosyllabic couplets. This early stage is attested by the High German poem *Vom Fuchs Reinhart,* by Heinrich (der Glîchezâre ?), a little masterpiece of 2,000 lines, freely adapted from a lost French original.

The status of the extant French "branches" of the *Roman de Renart* (about 30 in number, nearly 40,000 lines of verse) is controversial (*see* FRENCH LITERATURE). Even those branches (II–IV, I and X) which come closest to Heinrich's material are probably elaborations of a kernel poem utilized by him. The facetious portrayal of rustic life, the camel as a papal legate speaking broken French, the animals riding on horses and recounting elaborate dreams, suggest the atmosphere of St. Louis' reign, and point forward to the still more sophisticated "Nun's Priest's Tale" of Chaucer (*q.v.*). The main literary tradition descends from these branches and the Flemish adaptations of them by Aernout and Willem (*c.* 1250). These were the sources of the Dutch and Low German prose manuscripts and chapbooks, used in their turn by Caxton and subsequent imitators down to Goethe's *Reineke Fuchs* (1794). Because of the popularity of these tales the nickname

renard has replaced the old word *goupil* ("fox") throughout France.

REYNAUD, PAUL (1878–1966), French statesman, a conservative and patriotic republican, was the next to last premier of the Third Republic and an architect of the Fifth. Born at Barcelonnette, Basses-Alpes, on Oct. 15, 1878, and educated in Paris, he became a lawyer. He served in World War I on the Western Front and on a mission to Russia. In the Chamber of Deputies after the war he represented Basses-Alpes (1919–24) and then a Parisian constituency (from 1928). Between 1930 and 1932 he held successively the posts of minister of finance, of the colonies, and of justice. Out of office for the next five years, he advocated resistance to Nazi Germany and in 1935 called in vain for preparation for tank warfare, as recommended by Charles de Gaulle. As minister of justice under Édouard Daladier (from April 1938), Reynaud protested against appeasement of Germany over Czechoslovakia, but was dissuaded from resigning office (though he could still break with his parliamentary group, the Alliance Démocratique, when its leader, Pierre Flandin, sent congratulations to Hitler after the Conference of Munich). Appointed minister of finance (Nov. 1, 1938), he devalued the franc and sponsored measures of austerity to restore national solvency and to pay for better defenses.

In World War II Reynaud became premier on March 21, 1940. He strongly favoured Allied intervention in Norway, made De Gaulle undersecretary of state for war (with the rank of general), and, when France was collapsing, argued for standing by the British alliance. On June 16 he resigned, so as not to be a party to an armistice with Germany. He was arrested on Sept. 6 by the Vichy regime and spent the rest of the war in captivity.

After the liberation, Reynaud returned to politics, his vigorous physique unimpaired. As deputy for the Nord *département* (1946–62), he was an active spokesman for West European unity. He held office in two governments (1948 and 1950) and twice (1952 and 1953) tried to form cabinets of his own. Welcoming De Gaulle's accession to power, he presided in 1958 over the Consultative Committee on the drafting of the constitution of the Fifth Republic. In 1962, however, he forcefully denounced the Gaullist inauguration of an overtly presidential regime. He died in the American Hospital of Paris (Neuilly) on Sept. 21, 1966.

Reynaud's major publications are *La France a sauvé l'Europe* (1947, revised as *Au coeur de la mêlée, 1930–45*, 1951; Eng. trans., *In the Thick of the Fight, 1930–45*, 1955); and *Mémoires*, 2 vol. (1960–63).

REYNOLDS, SIR JOSHUA (1723–1792), English painter, perhaps the dominant figure in the history of British art, was born at Plympton, Devon, on July 16, 1723. He was educated at the Plympton grammar school and was well read in classical literature. Influenced by the essays of Jonathan Richardson, Reynolds aspired to become a painter, and in 1740 he was apprenticed for four years to Thomas Hudson in London. In 1743, however, he returned to Devon and began painting at Plymouth dock portraits that reveal his inexperience and that are very much in the tradition then prevailing. Returning to London for two years in 1744, he began to acquire his independent style and his knowledge of the old masters. An outstanding picture of this period is "Capt. the Hon. John Hamilton" (owned by the duke of Abercorn), which shows Reynolds' bolder style combined with a considered use of impasto.

Back in Devon in 1746 he painted his large group of the "Eliot Family," which clearly demonstrates his knowledge of the vast picture by Van Dyck at Wilton house, Wiltshire. In 1749 he sailed with his friend Augustus Keppel to Minorca, where he stayed for five months and endured the accident that permanently scarred his lip, the scar being a feature prominent in all his self-portraits. From Minorca he made his way to Rome, where he remained for over two years. There he was able to give full reign to his scholarship and to store his mind with the great masterpieces of classical and modern painting and sculpture. The impressions that he retained from this visit were to inspire his paintings and his *Discourses* for the rest of his life, for he felt that it was by allying painting with scholarship that he could best achieve his ambition of raising the status of his profession. He returned to England via Florence, Parma, Bologna and Venice, where he absorbed and noted the colour and composition of works by Titian, Tintoretto and Veronese. He was immediately seduced by Venetian colouring and, although all his life he preached the need for all young artists to study the classical forms of Michelangelo and Raphael, his own works are redolent of the light and shade of Venetian colouring.

In 1753 Reynolds settled in London, where he was to live for the rest of his life, first in St. Martin's lane and finally, after 1760, in Leicester square. From the first his success was assured, and by 1755 he was employing studio help, notably Giuseppe Marchi. The first great work from this period is "Commodore Keppel" (in the National Maritime museum, Greenwich, London). The pose is not original, being a reversal of that of the "Apollo Belvedere" statue in the Vatican, but the subject is shown striding along the seashore in a new and vital way. It could be said that with this portrait all of English portrait painting took on a new life and vigour and the tradition of Sir Godfrey Kneller was entirely destroyed. A painter could not always hope to have such a heroic sitter, but Reynolds was equally successful with the more domestic portraits of men and women. In these first years in London his knowledge of Venetian painting is very apparent; *e.g.*, the portraits of "Lord Cathcart" (owned by Lord Cathcart) and "Lord Ludlow" (at Woburn abbey, Bedfordshire). Of his domestic portraits the most enchanting is that of "Georgiana, Countess Spencer, and Her Daughter" (owned by Lord Spencer), painted in 1760, which is one of the greatest English portraits, full of tenderness and careful observation. In the 1760s he was more and more under the influence of the painters of the Bolognese school, and the pose and clothes of his sitters take on a more rigid, classical pattern, losing in consequence much of the sympathy and understanding he could have given them. It was from these portraits that he hoped to equate portrait painting with the "grand style," and they are indeed an illustration to much that he has to say in his *Discourses*. It has been suggested that the painting of "Garrick Between Tragedy and Comedy" (on loan from Lord Rothschild to King's college, Cambridge) is a parody of his own predicament, Comedy being painted in the softer and more domestic manner of Correggio and Tragedy in the classical manner of Guido Reni.

Reynolds was to realize his ambitions for his profession in a new and public way. Hitherto there had been no public exhibitions of contemporary artists in London, but in 1760 the Society of Artists was founded and the first of many successful exhibitions held. After some internal squabbles the patronage of King George III was sought and in 1768 the Royal Academy was founded. Although Reynolds' painting had found no favour at court, he was the obvious candidate for the presidency and the king confirmed his election and knighted him. Reynolds guided the policy of the academy with skill, and the pattern he set has been followed with little variation ever since. His yearly *Discourses* are some of the wisest words an older painter has offered to those beginning their careers, and they also clearly mirror many of his own thoughts

and aspirations, as well as his own problems of line versus colour and public and private portraiture.

From 1769 nearly all of Reynolds' most important works appeared in the academy, and this undoubtedly influenced the rather more public manner of his portraits. In certain exhibitions he included historical pieces, such as "Ugolino" (at Knole house, Kent), which were perhaps his least successful contribution to painting. Many of his child studies are tender and even amusing, though now and again the sentiment tends to be excessive; two of the most enchanting are "Master Crewe as Henry VIII" (owned by Lord O'Neil) and "Lady Caroline Scott as Winter" (owned by the duke of Buccleuch). His most ambitious portrait commission was the "Family of the Duke of Marlborough" (at Blenheim palace, Oxfordshire), which was shown at the academy of 1778. Although not wholly successful it is a monumental group entirely suitable to the house that holds it: a conversation piece enlarged to the scale of a history piece. It may have been the arrival of Thomas Gainsborough in London in 1774 that caused Reynolds to revert to a more informal mood.

In 1781 Reynolds visited Flanders and Holland, where he studied the work of Rubens, and this seems to have affected his own style as from that time the texture of his picture surface becomes far richer. This is particularly true of his portrait of the "Duchess of Devonshire and Her Daughter" (at Chatsworth house, Derbyshire). It was this last phase of dramatic and baroque style that influenced John Hoppner and Thomas Lawrence, but they paid perhaps more attention to the painting of silks and satins and rather less to the characterization. Reynolds was never a mere society painter or flatterer and he never forgot what James Northcote called, when writing of Allan Ramsay, the "mental part" of a portrait. It has been suggested that his deafness allowed Reynolds a clearer insight into the character of his sitters, the lack of one faculty sharpening the use of his eyes. His vast learning allowed him to vary his poses and style so often that the well-known remark of Gainsborough, "Damn him, how various he is!" is entirely understandable. In 1782 Reynolds had a paralytic stroke and about the same time he was saddened by bickerings within the Royal Academy. Seven years later his eyesight began to fail and he delivered his last *Discourse* at the academy in 1790. On Feb. 23, 1792, he died.

BY COURTESY OF THE TRUSTEES OF THE WALLACE COLLECTION

"NELLY O'BRIEN" BY SIR JOSHUA REYNOLDS, 1763

Reynolds preferred the company of men of letters to that of his fellow artists. Although his 14th *Discourse* is a tender and moving appreciation of Gainsborough, who stood for so much that he himself disliked in painting, it was in the company of Dr. Johnson and of Edmund Burke and Oliver Goldsmith that Reynolds was happiest. When Goldsmith died, Reynolds could not bring himself to paint for a whole day, and the moving essay he wrote on his friend showed that he could write a portrait as well as he could paint one. Reynolds and his friends were members of "The Club," which he established in 1764. He never married and his house was kept for him by his sister Frances.

Reynolds' state portraits of the king and queen were never considered a success and he seldom painted for them, but the prince of Wales patronized him extensively and there were few distinguished families or individuals who did not sit to him. Nonetheless some of his finest portraits are those of his intimate friends and of fashionable women of a questionable way of life. Unfortunately Reynolds' technique was not always entirely sound, and many of his paintings have suffered as a result. After his visit to Italy he tried to produce the effects of Tintoretto and Titian by using transparent glazes over a monochrome underpainting, but the carmine he used for his flesh tones was not permanent and even in his lifetime began to fade, causing the overpale faces of many surviving portraits. An example of this can be seen in the "Roffey Family Group" (in Birmingham art gallery, Eng.). This paleness has been increased by injudicious cleaning in certain paintings. The most interesting picture to show how Reynolds worked is the unfinished double portrait of "Burke and Lord Rockingham" (in Fitzwilliam museum, Cambridge). In the 1760s Reynolds began to use bitumen more extensively, which was detrimental to the paint surface. Of his later style the "Duchess of Devonshire and Her Daughter" is in almost matchless condition. Though a keen collector of old master drawings, he was never a draftsman and indeed few of his drawings have any merit, but there is an interesting early "Self-Portrait" drawing (owned by Lord Harcourt) and a design for "Comedy" (in the Ashmolean museum, Oxford). His ledger books from 1755 to 1789, which, with a few gaps, are preserved, make it possible to date most of his sittings with reasonable accuracy.

His work is represented in most public and private collections and he is splendidly shown in the royal collection. The National gallery, London, has, among other paintings, "Capt. Tarleton," "Lord Heathfield," "The Countess of Albemarle" and "Three Graces Adorning a Term of Hymen." Among his portraits in the National Portrait gallery, London, are those of "Johnson," "Boswell" and his own early "Self-Portrait" shading his eyes. The Wallace collection, London, has "Nelly O'Brien," "Mrs. Carnac" and "Miss Bowles." Private collections particularly rich in his work include those of the duke of Bedford, duke of Devonshire, duke of Buccleuch, earl of Harewood, George Howard, earl of Ilchester, John Wyndham and Lord Spencer. An interesting portrait of Reynolds, not by his hand but by Angelica Kauffmann, belongs to Lord Morley.

His work is not richly represented in the United States, although his great portrait of "Mrs. Siddons as the Tragic Muse" is in the Huntington library, San Marino, Calif.; and Washington and New York also have important examples.

REYNOLDS, OSBORNE (1842–1912), English engineer and physicist, best known for his work in the fields of hydraulics and hydrodynamics, was born at Belfast on Aug. 23, 1842. Gaining early workshop experience and graduating at Queens' College, Cambridge, in 1867, he became in 1868 the first professor of engineering in the Owens College, Manchester. He was elected a fellow of the Royal Society in 1877 and a Royal medalist in 1888. He retired in 1905 and died at Watchet, Somerset, on Feb. 21, 1912.

Reynolds' studies of condensation and the transfer of heat between solids and fluids brought radical revision in boiler and condenser design, while his work on turbine pumps laid the foundation of their rapid development. A fundamentalist among engineers, he formulated the theory of lubrication (1886), and in his classical paper on the law of resistance in parallel channels (1883) investigated the transition from smooth, or laminar, to turbulent flow, later (1889) developing the mathematical framework which became standard in turbulence work. His name is perpetuated in the "Reynolds stress," or drag exerted between adjacent layers of fluid due to turbulent motion, and in the "Reynolds number" (*see* AERODYNAMICS), which provides a criterion for dynamic similarity and hence for correct modeling in many fluid flow experiments. He developed and exploited corresponding criteria for wave and tidal motions in rivers and estuaries, and made pioneering contributions to the concept of group velocity. Among his other work was the explanation of the radiometer and an early absolute determination of the mechanical equivalent of heat. Reynolds' *Scientific Papers* were published in three volumes (1900–03).

See A. H. Gibson, *Osborne Reynolds and His Work in Hydraulics and Hydrodynamics* (1946). (C. H. B. P.)

REZAIYEH (formerly URMIA or URUMIA), the capital of the *ostan* (province) of Western Azerbaijan, Iran, lies on a large plain west of Lake Urmia, 75 mi. (120 km.) WSW of Tabriz. The population in 1956 was 67,605, mainly Turkish, with Kurdish, Assyrian (Nestorian), and Armenian minorities. The plain of Urmia has plenty of water for irrigation and is very fertile; cultivation, especially of fruits and tobacco, is of a high standard.

Ancient remains are scattered over the plain. The kingdom of Urartu (*q.v.*) has left some marks. During the Muslim period the region was frequently dominated by Kurdish princes. For long periods the city belonged to the Ottoman Empire. About 1900, Christians (Nestorians and Orthodox) formed 45% of the total population. In July 1918, however, there was a large-scale exodus of Christians after the retreat of the Russians. Most of the remaining Christians were massacred in the same year and the remnant of 600 transferred to Tabriz. Later, some survivors were repatriated by the Iranian government and agriculture was fully restored. Rezaiyeh is connected by main road with Tabriz via Khoi northward and with Kermanshah via Mahabad and Sanandaj southward. There is an airfield in the vicinity. (H. Bo.)

REZANOV, NIKOLAI PETROVICH (1764–1807), Russian trader, diplomat, and administrator who was a founder and an outstanding executive of the great Russian-American Company which played a major part in the history of Alaska (*q.v.*) and of the North Pacific. He was born in St. Petersburg on April 8 (new style; March 28, old style), 1764.

Having met G. I. Shelekhov, head of the Shelekhov-Golikov Fur Company, in 1788, Rezanov became interested in that merchant's project of obtaining a monopoly of the fur trade of the Russian settlements along the northwestern coast of America. He entered into partnership with Shelekhov and, on the latter's death (1795), made himself the leading spirit of the company. Wanting privileges analogous to those granted by Great Britain to the East India Company, he had just persuaded the empress Catherine II to sign a charter for him when she died (1796). He then had to begin new negotiations with the emperor Paul, whom he finally induced (1798–99) to grant to the Russian-American Company dominion for 20 years over the American coast northward from latitude 55° and over the Aleutian and the Kuril Islands. This "trust," which crowded out the smaller enterprises, was at first a source of great revenue to Rezanov and to the other 400 shareholders (including members of the imperial family).

Rezanov did much to instigate the voyage of Adam Ivan Krusenstern on the first Russian circumnavigation of the globe (1803–06). He sailed with this expedition from Kronshtadt across the Atlantic and round Cape Horn to Kamchatka, whence in 1804 he went to Japan on an unsuccessful mission as the emperor Alexander I's ambassador. Returning to Kamchatka in 1805, he there received orders to remain in the North Pacific area as imperial inspector and plenipotentiary of the company, and to correct the abuses that were ruining the great enterprise. He traveled slowly to Sitka (Novo-Arkhangelsk, or New Archangel, centre of the company's colonial administration) by way of the islands.

At the end of a winter in Sitka, Rezanov sailed for the Spanish settlements in California to trade his wares for foodstuffs (of which the Russian colonies were seriously in need) and to arrange a treaty for the provisioning of the company's colonies twice a year from New Spain. Storms prevented his taking possession of the mouth of the Columbia River for Russia during his voyage, but he reached San Francisco early in April 1806. Though he was received with courtesy, he was told that the laws of Spain forbade the colonies to trade with foreign powers, and that the governor of all the Californias was incorruptible. Rezanov would have failed again had it not been for a love affair with the daughter of the *comandante* of San Francisco, Don José Argüello, and for his personal skill in winning the clergy over to his cause. As it was, when he sailed for Sitka six weeks later, his ship's hold was full of breadstuffs and dried meats, he had the perplexed governor's promise to forward a copy of the treaty to Spain at once, and he was affianced to the most beautiful girl in California. From Sitka he returned again to Kamchatka, whence he dispatched ships to wrest Sakhalin from the Japanese. He then started overland for St. Petersburg to obtain Alexander I's signature to the treaty. He died of fever and exhaustion in Krasnoyarsk, Siberia, on March 13 (N.S.; 1, O.S.), 1807.

Rezanov was deeply and humanely concerned for his employees and for the wretched natives who were little more than the slaves of the company. His correspondence with the company shows clearly that he wished to annex to Russia the western coast of North America, and to encourage immediate emigration from Russia on a large scale. His Californian treaty, however, was never ratified; his reforms were allowed to lapse; the fortunes of the colonies deteriorated, and his Spanish fiancée became a nun. One of the ablest and most ambitious men of his time, he was forgotten in the cemetery of a poor Siberian town.

REZA SHAH PAHLAVI (1878–1944), shah of Iran from 1925 to 1941, was born at Alasht, in the Savad Kuh district of the northern province of Mazanderan, on March 16, 1878. His father, who died soon after his birth, was an army officer. Entering the army as a private soldier at an early age, he rapidly obtained commissioned rank and showed such exceptional aptitude and ability that he rose at length to the command of the Persian Cossack brigade.

Persia, because of its involuntary involvement in World War I and the ineptitude of Ahmad Shah and his ministers, had been reduced to a sad plight by the beginning of 1921. In February of that year the patriotic leader and reformer Sayyid Zia ad-Din Tabatabai, in conjunction with Reza Khan and his Cossack brigade, carried out a *coup d'état* in Teheran and took over the government, Sayyid Zia becoming prime minister and Reza Khan minister of war and commander in chief. In 1923 Reza Khan became prime minister and virtual ruler of the country. At this stage of his career Reza Khan modeled himself closely on his Turkish contemporary Mustafa Kemal. There was for a time a movement in Persia in favour of abolishing the monarchy and substituting a republic, with Reza Khan as president; this idea, however, met with much opposition, particularly from the *'ulama'* (learned men or "clergy"), who were alarmed by acts of the Turkish government

which they regarded as anti-Islamic. It was therefore decided to retain the monarchy but to depose Ahmad Shah (who had been absent in Europe for some time) and to place Reza Khan on the vacant throne. These steps were accordingly taken, and Reza Khan became shah on Dec. 16, 1925.

Reza Shah proceeded to carry out many reforms on Western lines, largely modeled on those of Mustafa Kemal. He ruthlessly suppressed brigandage, curbed the power of the tribes, and made the authority of the central government effective throughout the country. Though some of Reza Shah's reforms were ill-conceived and in certain cases harshly enforced, there can be no doubt that, on the whole, he contributed many benefits to his country, especially in the earlier part of his reign. His greatest achievement was the construction of the Trans-Iranian Railway, which was completed in 1938 without recourse to foreign loans. The shah likewise paid much attention to the improvement and development of the road system.

Being strongly desirous of modernizing the industries of his country, and not wishing to be beholden to either Great Britain or the U.S.S.R. for help, he sought and obtained much machinery and many technicians from Germany. When World War II broke out, the presence of about 2,000 German technicians in Persia (Iran after 1935) aroused fears in Great Britain lest these men might destroy the refinery of the Anglo-Iranian Oil Company at Abadan and put its pipeline system and oil fields out of action. After Germany's attack on the U.S.S.R. in 1941, the necessity arose for the Western allies to send military supplies across Iran to the hard-pressed Russians. When Great Britain and the U.S.S.R. asked for permission for these supplies to be sent, Reza Shah refused. The two powers then repeated their request and also demanded the expulsion of the German technicians, who, they feared, might sabotage the Trans-Iranian Railway. The shah, however, again refused, whereupon British and Soviet troops entered Iran. Reza Shah abdicated in favour of his eldest son, Mohammed Reza Pahlavi (*q.v.*), on Sept. 16, 1941. The former shah was then exiled first to Mauritius and later to South Africa. He died in Johannesburg on July 26, 1944. *See* also PERSIAN HISTORY: *Pahlavi Dynasty.*

See J. M. Upton, *The History of Modern Iran: an Interpretation* (1960); Mohammad Reza Pahlevi, *Mission For My Country* (1961). (L. Lo).

RHAMNACEAE, the buckthorn family, a group of thorny shrubs, woody vines, and trees found in the warmer parts of both hemispheres. It includes 45 genera and about 550 species of dicotyledonous plants. Large genera are *Rhamnus* with about 230 species, *Zizyphus* with 100 species, and *Phylicia* with 90 species. Jujube (*q.v.*), or the Chinese date, native to Asia, is the fruit of *Zizyphus jujube* (*Z. vulgaris*), and the Indian jujube is the fruit of *Z. mauritiana.* The bark of various species of *Rhamnus* is utilized in the practice of medicine, cascara sagrada (*q.v.*) being that of the western American *R. purshiana. Ceanothus,* a genus highly developed in the western United States, is known as the California lilac. *See* also BUCKTHORN. (E. D. ML.)

RHÄTICUS (RHETICUS), a surname derived from Rhaetia (Austria), the district of his birth, by GEORG JOACHIM VON LAUCHEN (1514–1576), astronomer and mathematician who, as an associate of Nicolaus Copernicus (*q.v.*), was among the first to adopt and to spread his heliocentric theory. Rhäticus was born at Feldkirch on Feb. 16, 1514. In 1537 he was appointed to a chair of mathematics and astronomy at Wittenberg. He was much attracted by news of Copernicus' heliocentric theory and in 1539 he resigned his professorship and went to Frauenburg, where he studied for two years with Copernicus. Rhäticus published the first exposition of the new heliocentric views in his *De libris revolutionum . . . Nic. Copernici . . . narratio prima . . .* (1541) and for about ten years thereafter produced ephemerides based on the Copernican system. He persuaded Copernicus to complete the great *De revolutionibus orbium coelestium* and to permit him to take the manuscript to Nürnberg for publication. Because of the religious objections of Luther and others, Rhäticus left Nürnberg before *De revolutionibus* was actually published in 1543, and moved to Leipzig.

From his time at Wittenberg until his death at Kassa, Hung., on Dec. 5, 1576, Rhäticus worked on his great treatise *Opus Palatinum de triangulis,* which was published posthumously in 1596 by Valentine Otto, mathematician to the electoral prince palatine. The work contains tables of sines, cosines, tangents, etc., in intervals of ten seconds of arc and calculated to ten decimal places. Rhäticus proposed to compute similar tables to 15 decimal places, but did not live to complete the task. The table of sines on this scale was published in 1613 by B. Pitiscus (1561–1613) under the title *Thesaurus mathematicus,* Pitiscus himself completing certain of the calculations. (CN. A. R.)

RHAZES (ABU-BAKR MOHAMMED IBN ZAKARIYYA AR-RAZI) (*c.* 865–923 or 932), undoubtedly the greatest physician of the Islamic world, also a philosopher of remarkable independence of mind and a well-known alchemist, was a Persian Muslim, born in the city of Rayy (Ray) about 865. The tradition that he was an alchemist before he became thoroughly acquainted with medicine may be reliable. He became chief physician in a new hospital at Rayy and subsequently held a similar position in Baghdad for some time. As so many "intellectuals" in his day, he lived at different small courts enjoying the protection of minor rulers. He claimed to fulfill in his own time the function of a Socrates in philosophy and that of a Hippocrates in medicine. He died in his native city in 923 or 932.

The two most important medical works of Rhazes are the *Kitab al-Mansuri,* which he composed for Mansur ibn Ishak, the ruler of Rayy, and which became well known in the west in Gerard of Cremona's 12th-century Latin tránslation; and *Al-Hawi,* the "Comprehensive Book," in which he surveys Greek, Syrian, and early Arabic medicine in their entirety, as well as some Indian medical knowledge, adding his own considered judgment and his own medical experience throughout. Among his numerous minor medical treatises, *A Treatise On the Small Pox and Measles* is famous, having been translated into Latin and various modern languages and into Byzantine Greek.

The philosophical writings of Rhazes (*see* ARABIC PHILOSOPHY) were completely neglected for centuries: not until the 20th century did their importance come to be appreciated again. He claims to be a Platonist, and his views are everywhere at variance with the philosophy of such thinkers as al-Farabi, Avicenna, and Averroes. He was probably acquainted with Arabic translations of Democritus and followed a similar line in his own atomic theory of matter. His *Autobiography* is rather a spirited defense of the philosophical way of life as he understood it than an account of actual events (Eng. trans. by A. J. Arberry in the *Asiatic Review,* 1949). *On Spiritual Medicine* (Eng. trans. by A. J. Arberry, *The Spiritual Physick of Rhazes,* London, 1950) is a popular ethical treatise. The main alchemical work of Rhazes is the *Secret of Secrets* (German trans. by J. Ruska, 1937).

RHEA, in Greek mythology an age-old goddess, probably pre-Hellenic in origin, as her connection with Crete suggests. A daughter of Uranus and Gaea (Heaven and Earth), she married her brother Cronus (*q.v.*). His parents informed Cronus of a prophecy that one of his children was fated to overthrow him. Accordingly he swallowed his children Hestia, Demeter, Hera, Hades, and Poseidon soon after they were born. Rhea, however, concealed the birth of Zeus in a cave on Mt. Dictys in Crete, and the Curetes (*q.v.*) drowned the infant's cries by performing their war dance in armour. Cronus was given a stone wrapped in swaddling clothes, and swallowed it in the belief that it was Zeus. Subsequently Cronus was vanquished by Zeus and forced to disgorge the swallowed children.

Rhea was worshiped sporadically throughout the Greek world, often in association with Cronus or Zeus, her cult being well at-

tested at Athens, in Arcadia, at Olympia, and especially in Crete. She was associated with fruitfulness and had affinities with Earth, with the Mother Goddess, and with Cybele (Rhea-Zeus corresponding to Cybele-Attis; *see* GREAT MOTHER OF THE GODS). No doubt her cult could be as primitive and barbaric as her myth; but it could also be spiritualized into the worship of a divine mother, whose tender care for humanity won a ready response from her children, an archetypal religious concept of extreme antiquity in the Mediterranean area.

See H. J. Rose, *A Handbook of Greek Mythology* (1958).
(D. E. W. W.)

RHEA, the American cousin of the African ostrich (*q.v.*), a giant flightless ratite bird confined to South America. Three species are recognized: *Rhea americana,* ranging from Paraguay to Patagonia; *R. darwini,* confined to Patagonia; and *R. macrorhyncha,* of northeast Brazil. Considerably smaller than the ostrich, about four feet tall, the rheas are further distinguished by the possession of three toes, the absence of fine plumes, and the general brownish colour of the feathers, which, in *R. darwini,* are tipped with white. The feathers have a considerable market value. The rhea is polygamous, and the cock bird performs the duties of incubation. Rheas frequently associate with deer or guanacos to form "mixed herds" similar to those formed by the ostrich with zebras and antelopes.

RHEDEN, a commune in the province of Gelderland, Neth., comprises the villages of Velp, Rheden, De Steeg, Ellekom, Dieren, Spankeren, and Laag Soeren, which lie along the highway from Arnhem to Zutphen, between the IJssel River and the Veluwe hills. Pop. (1960) 38,358 (mun.). Velp, Rheden, Ellekom and Spankeren have 11th- and 12th-century churches. Other old buildings are the 16th-century castles of Biljoen (Velp) and Middachten (De Steeg) and the 12th-century Gelderse Tower. A striking modern building is the high school in Velp (1959). The commune is served by railways to Apeldoorn, Arnhem, and Zutphen. Manufactures include steel and concrete constructional components, enamelware, and clothing. The tourist industry is important, as much of the commune is in the Veluwezoom National Park.

RHEE, SYNGMAN (1875–1965), Korean statesman, first president of the Korean Republic, was born on April 26, 1875, in Whanghae province, Korea. He completed a traditional classical education and then entered a Methodist school, where he learned English and enough Western thought to become a confirmed Nationalist and ultimately a Christian. He joined with other Korean leaders in 1896 to form the Independence Club and served briefly as a member of the privy council. When reactionary elements destroyed the club in 1897, Rhee was arrested and imprisoned until 1904. On his release he went immediately to the United States, where he attended George Washington University (A.B. 1907), Harvard (M.A. 1908), and Princeton (Ph.D. 1910). He was the first Korean to earn a doctoral degree in an American university. While a student he made frequent but unsuccessful appeals to the United States to save his country from Japan. When he returned home in 1910 he found it impossible to hide his hostility toward Japanese rule, and after short terms as a YMCA worker and high school principal he returned to the U.S. in 1912.

For the next 30 years Rhee served as a spokesman for Korean independence, publicizing Korea's plight and trying in vain to win international support for his cause. In 1919 he was elected president of the Korean Republic in exile, holding that post for 20 years. He returned to Korea in 1945 after spending the war years in trying to secure Allied promises of Korean independence. Elected president of the Republic of Korea in 1948, he was reelected in 1952, 1956, and 1960.

As president of the ROK, Rhee's great objective was the freedom and unification of his country. He used his broad powers to remove domestic opposition to his program, and even defied the United Nations when he felt that body threatened those ends (for Rhee's participation in the Korean War *see* KOREAN WAR). He purged the national assembly and outlawed the opposition Progressive Party, whose leader was executed for treason. Rhee controlled the appointment of mayors, village headmen, and chiefs of police, but in 1956 failed to prevent the election of an opposition vice-president. Government claims that the March 1960 elections gave Rhee over 90% of the popular vote (55% in 1956) provoked student-led demonstrations resulting in heavy casualties and demands for his resignation, supported by the unanimous vote of the national assembly. Rhee resigned April 27, and left for exile in Hawaii. A caretaker government pledged new elections and the repudiation of the most widely criticized of Rhee's domestic and foreign policies. Rhee died July 19, 1965, in Honolulu. *See* also KOREA: *History.* (F. G. WN.)

RHEGIUM: *see* REGGIO DI CALABRIA.

RHEINBERGER, JOSEPH GABRIEL VON (1839–1901), German composer and teacher whose organ sonatas are among the finest 19th-century works for that instrument, was born at Vaduz, Liechtenstein, on March 17, 1839. As a child he studied the organ in his native town and became organist at the parish church there when only seven years old. He later studied at Feldkirch and Munich, and in 1867 became professor of organ and composition at the Munich Conservatory. Among his pupils in composition were E. Humperdinck, E. Wolf-Ferrari, W. Furtwängler, and the U.S. composers G. W. Chadwick and H. W. Parker. Besides 20 organ sonatas, Rheinberger wrote 4 operas and much church music and chamber music. He received a title of nobility in 1894. He died at Munich on Nov. 25, 1901.

See H. Grace, *The Organ Works of Rheinberger* (1925).

RHEINE, a town of West Germany in the *Land* (state) of North Rhine-Westphalia (Nordrhein-Westfalen), Federal Republic of Germany, is situated on the Ems 31 mi. (50 km.) W of Osnabrück by road. Pop. (1961) 44,322. St. Dionysius' Church (1484), the main square, Bentlage Castle, the Gottesgabe Bath with its pump room, and the zoo are of interest. Rheine is a junction of eight railway lines, the chief being the Ruhr-North Sea and the Berlin-Hanover-Hook of Holland routes. Nearby is the secondary airport of Rheine-Eschendorf. Industries include cotton spinning, weaving, and the manufacture of stockings, machinery, and lime. The town suffered in the Thirty Years' War and was severely damaged in World War II, but it has been rebuilt.

RHEINHAUSEN, a town of West Germany in the *Land* (state) of North Rhine-Westphalia (Nordrhein-Westfalen), Federal Republic of Germany, lies on the left bank of the Rhine a short distance upstream from Duisburg. Pop. (1961) 68,126. The site was chosen by the Krupps for a large iron and steel plant, which started production in 1898. Rheinhausen has docks to handle imported iron ore, fuel, and limestone. The town grew up to house workers at the Krupp plant. It was formed in 1923 through the incorporation of Hochemmerich and Friemersheim and was chartered in 1934. Neither the town nor the plant suffered serious damage during World War II, and the works, which have remained in the possession of the Krupp family, have been fully restored. (N. J. G. P.)

RHEINLAND PFALZ: *see* RHINELAND-PALATINATE.

RHENANUS, BEATUS (BEATUS BILDE) (1485–1546), German humanist and historian noted for his editions of Latin texts, was born in Schlettstadt (Alsace) in 1485. An intimate friend of Erasmus, he was from 1511 to 1526 one of the scholars working for Johann Froben's press at Basel. Using recently discovered Rhineland manuscripts whenever possible, he edited Tertullian (*editio princeps,* 1521) and the historians Curtius Rufus (1518), Velleius Paterculus (*editio princeps,* 1520), Procopius, Jordanes, and Agathias (1531), Tacitus (1533), and, in collaboration with Sigismund Gelenius, Livy (1535). His *Res Germanicae* (1531), a pioneer study of the early history of the Germans, was notable for the care with which it dated and handled its sources and for its discussion of social, cultural, and economic developments. But his life of Erasmus (1540) was, disappointingly, a mere panegyric. He died at Strasbourg on Aug. 28, 1546.

See A. Horawitz in *Sitzungsberichte der philos.-hist. Classe der Kaiserlichen Akademie der Wissenschaften zu Wien,* vol. 70–74 (1872–74); G. C. Knod, *Aus der Bibliothek des Beatus Rhenanus* (1889).
(R. R. Bo.)

RHENIUM, a very rare metallic element discovered by Ida and Walter Noddack in 1925. Its chemical symbol is Re; its atomic number 75; and its atomic weight 186.2. Until 1965 the annual world production of rhenium was conveniently estimated in kilograms (or pounds). The metal and its alloys have found limited application as fountain-pen points, high-temperature thermocouples, catalysts, electrical contact points, instrument-bearing points, and in electric components.

Rhenium is widely distributed in a variety of minerals but usually in concentrations below 0.1 part per 1,000,000. It occurs in concentrations as high as 10 to 20 parts per 1,000,000 in molybdenum sulfide ores, and to a lesser extent in sulfidic copper ores. It is probably present as its stable disulfide (ReS_2). The recovery of rhenium follows from the concentration of its volatile heptoxide in the flue dust during the smelting of molybdenite ore, or from its concentration with the platinum metals in the "anode sludge" during electrolytic copper refining. The extracted element is recrystallized as the sparingly soluble potassium perrhenate ($KReO_4$). This material is transposed to the ammonium salt and reduced in hydrogen to give black metal powder. The powder may be compressed and sintered in hydrogen at an elevated temperature to give sintered bars (density, 19). Cold working and annealing permit the fabrication of wire or foil.

The silvery massive metal has a density of approximately 21.0 g. per cc., melts at about 3,180° C, and is extremely hard; its wear resistance is good and it is not easily corroded. The powder slowly oxidizes in air above 150° C and rapidly at higher temperatures to form volatile Re_2O_7. This yellow, stable, and relatively nontoxic oxide is the anhydride of perrhenic acid ($HReO_4$), which results from dissolution of the metal in hydrogen peroxide or nitric acid. The metal is not soluble in hydrochloric acid, and dissolves only with difficulty in other acids. The perrhenates, the heptoxide, and perrhenic acid have been extensively studied; unlike the corresponding manganese compounds, the (VII) state of rhenium is its commonest and most stable form. Perrhenate, unlike permanganate, is only a weak oxidant, comparable in strength with ferric ion.

There is some evidence for the existence of rhenium in each of the oxidation states from (VII) through (−I). The solution chemistry of rhenium is quite complex because of the large number of possible, acid-base sensitive, disproportionation reactions. The best characterized oxides are Re_2O_7; the insoluble red trioxide (ReO_3); and the black dioxide (ReO_2). The existence of an unstable black (possibly impure) sesquioxide (Re_2O_3) is probable, and both a monoxide and a suboxide have been reported. A number of tungsten, arsenic, silicon, and other rhenium alloys are known, and the heated metal reacts more or less readily with many nonmetals such as sulfur, phosphorus, or the halogens. As does tungsten, rhenium forms numerous anhydrous halides or oxyhalides with fluorine, chlorine, or bromine, which are hydrolyzed by water. The hexafluoride (ReF_6), pentachloride ($ReCl_5$), tribromide ($ReBr_3$), and two simple iodides (ReI_3 and ReI) have been reported. The trichloride ($ReCl_3$) is a trimeric red solid which behaves as a nonelectrolyte in solution; on heating, it emits a green vapour from which metal may be deposited by thermal decomposition. Complex rhenium (IV) halides of the type K_2ReX_6 have been reported for all four of the common halogens.

There are two naturally occurring isotopes: with mass numbers 185, which is stable, and 187, which is radioactive and the more abundant; radioactive isotopes with mass numbers 182, 183, 184, and 188 have been prepared. The arrangement of electrons in the unfilled orbits (O and P) is: $5s^2$, $5p^6$, $5d^5$, $6s^2$.

(C. L. R.)

RHEOLOGY (from the Greek *rheein,* "to flow") is the science of the deformation and flow of matter. The subject traditionally excludes hydrodynamics and the classical theory of elasticity, which are not normally concerned with the properties of specific materials. Rheology is a branch of physics but, because of its concern with the composition and structure of flowing and deformed materials and with the rheological behaviour of components of living organisms, it has applications in chemistry, engineering, biology, and medicine.

Early History.—Empirical studies of flow and deformation began in very early times. In a conical water clock from an Egyptian tomb of the 16th century B.C., the sides slope at an angle which suggests a correction deliberately made to allow for changes in the viscosity of the water corresponding with variations of nighttime temperature. Early Indian philosophers attempted to explain the rheological properties of materials in terms of what would now be called their atomic and molecular constitutions. Among Greek philosophers, Heraclitus claimed that everything is in a state of flux; his dictum was *panta rhei* ("everything flows").

Quantitative Studies.—The first quantitative experiments probably were those of Robert Hooke, who in 1660 worked with coiled and suspended weights on the ends of long metal wires, measuring the extensions of the wires in terms of distances of the weights from the ground. From these experiments he derived his law *ut tensio sic vis:* "as the extension, so is the force." E. Mariotte in France independently propounded the law in 1680. Hooke's law describes the simplest type of deformation. The atoms of the metal are strained out of their positions of equilibrium in which attractive and repulsive forces are balanced, the energy being stored potentially until the load is released, when the original form is restored.

Newton suggested in the *Principia* (1687) that "the resistance which arises from the lack of slipperiness of the parts of a liquid, other things being equal, is proportional to the velocity with which the parts of the liquid are separated from one another." In this simplest type of steady flow, all the energy is dissipated as heat and the removal of the driving force does not lead to any recovery.

Static friction, requiring that a limiting force be applied before flow or sliding can take place, was studied first by Leonardo and then by G. Amontons (1663–1705), C. A. Coulomb (1736–1806), and others (*see* FRICTION). Here again, energy is dissipated as heat. This and other aspects of rheology make technical use of the terms "stress" and "strain," which are almost synonymous in ordinary English. "Stress" refers to the whole system of forces (per unit area) acting on the surface of a body and "strain" to the changes of shape and volume associated with these forces. (For precise definitions, *see* ELASTICITY.)

In the latter half of the 19th century, studies were made, mainly in Germany, on the stretching of filaments, rubber strands, and wires under constant load (creep). L. Boltzmann proposed a principle of superposition to define conditions under which the amount of creep would be independent of the conditions of stressing, whether by a single load or by intermittent loads. The experiments led to theoretical treatments involving the statistical distribution of elements in creep and in stress relaxation under constant deformation.

J. C. Maxwell proposed (1868) a treatment for certain systems having imperfect elasticity; *i.e.,* those in which the stress gradually relaxes under constant strain at a rate which, in the simplest cases, is proportional to itself. Such systems, now called elastico-viscous, may be described in terms of a viscosity (ratio of stress to rate of flow), or of an elastic modulus (ratio of stress to initial strain), or of the ratio of these quantities, known as the relaxation time. The corresponding system, called visco-elastic, in which an elastic element is damped by a viscous unit in parallel, has a ratio of viscosity to elastic modulus called the retardation time. Priority in the study of this system is generally ascribed to Lord Kelvin. In time it became apparent that many real materials are neither perfectly elastic nor viscous, nor do they obey the simple combined equations which follow from the treatments of Maxwell and Kelvin. As early as 1889, F. N. Shvedov in Russia demonstrated the need for a static frictional term to account for the flow of certain complex materials; and in 1904–06 F. T. Trouton in England, in comparing conditions in tensile and shear experiments on pitch, implicitly postulated the same requirement. (Shear is the sliding over each other of parallel planes.)

Modern Rheology.—The founding of modern rheology is generally ascribed to E. C. Bingham of Easton, Pa. His early work

on paints and clays established the existence of a type of plasticity such that when an increasing shearing stress is applied to a suspension or paste, there is no appreciable flow until a well-defined critical stress ("yield-value") is reached, after which the rate of flow is proportional to the excess of stress over yield-value.

Bingham appreciated the need for cooperation among industrialists and biologists working with complex systems of flow and deformation and, in 1929, he and a group of friends defined the term rheology and started a society for its study (*see* below). Very soon, those who worked with bitumens, concrete, tar, soils, fibres, starch, cheese, flour doughs, and various synthetic high polymers found it convenient to describe behaviour in terms of models consisting of Hookean springs, Newtonian viscous elements ("dashpots"), and static frictional "sliders" linked in series and in parallel. It was soon realized, however, that many of the models were equivalent to one another, and that they could all be grouped into a small number of "canonical types." The organization and naming of the principal types was largely the work of M. Reiner.

Early attempts to construct models and to associate their elements directly with molecular mechanisms were not, on the whole, successful. Rheologists gradually accepted the view that models are only helps to envisage the meaning of the equations they represent. Moreover, in the late 1920s many systems were found which did not conform easily to this type of treatment. Wolfgang Ostwald and his school in Germany, and A. de Waele in England, then proposed equations according to which rates of flow are proportional to powers of the applied stress. The decision as to which type of treatment more adequately fitted the experimental data was generally settled on purely statistical grounds. It gradually became possible, especially in the field of high polymers, to relate rheological data to molecular constitution as determined by independent means. For a time there was a tendency to regard as "empirical," and in some sense inferior, any rheological treatment which did not purport to do this.

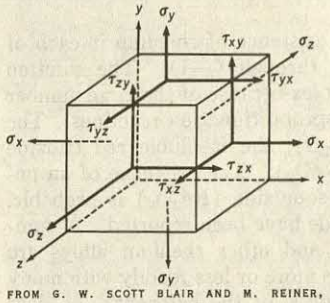
Early in the second half of the 20th century, however, the phenomenological approach was considerably extended and ceased to be regarded with distrust, partly because so many very complex modes of behaviour were discovered which were better classified phenomenologically than in terms of their molecular correlates. Another advantage of the phenomenological approach is that it often draws together systems that behave alike but whose molecular or atomic mechanisms differ greatly. Thus many interesting comparisons have been made between creep and relaxation of metals and of noncrystalline materials having different ultimate structures.

As more and more complex systems were investigated, the spring-dashpot-slider models became, very often, mere linear units within nonlinear distributions; the distribution functions (relaxation and creep functions) yielding quantities which describe the behaviour of the materials. This amounted to a return to the concepts of E. Wiechert, F. Kohlrausch, and others, 50 years earlier.

Many systems flow and deform in ways which depend not only on the applied stress but on the previous stress-and-strain history. The extreme case is that of a perfectly solid jelly with a characteristic rigidity modulus (ratio of intensity of shear stress to shear strain). This, on shearing, breaks down into a simple liquid of measurable viscosity, the jelly being re-formed on subsequent resting. This characteristic of liquefying on disturbance and solidifying at rest, reversibly and without change of temperature, was named thixotropy (Greek *thixis*, "touch") by H. Freundlich and his school; and, for a time, all less complete changes of that kind, involving merely a reversible fall in consistency on shearing, were called "false-body" changes. But, although some rheologists, notably J. Pryce-Jones, insisted on the quite distinct nature of these two phenomena, the term thixotropy was eventually used to cover both. Freundlich himself, in his later papers, used the term to include materials which do not exist as perfect solids and liquids. There are many examples: some clays, paints, inks, honey, etc. Some materials show "negative thixotropy"; *i.e.*, they increase their consistency reversibly on shearing and standing; and many more offer an increasing resistance to shear but do not recover, or recover only slightly, on resting. At one time all such behaviour was classed as "dilatancy" but it was later generally accepted that this term should only be used where a real dilatation, or moving of component particles into a more open form of packing (as originally studied by Osborne Reynolds for wet sand), can be demonstrated. The corresponding irreversible softening processes have been called "rheodestruction" (etymologically an unfortunate term; "rheomalaxis" would be better).

Many systems show a lower apparent viscosity (ratio of shear stress to shear rate) at higher shear rates either with or without any marked yield-values. Such behaviour is distinguishable from thixotropy only in terms of the magnitude of the time of resetting. If some structure is destroyed by rapid shearing (*i.e.*, if it possesses "shear thinning") but recovers so fast that there is always experimentally a unique value for the apparent viscosity for each value of shear-rate, few rheologists would describe this behaviour as thixotropic. The attitude of most is philosophically not unreasonable: glass and pitch are liquids, even at room temperature, if measurements are made over long periods of time, but for all practical purposes they are regarded as solids.

The Tensorial Approach.—The state of stress and the strain of an elastic body are described in terms of the whole combination of forces and of changes in volume and form to which it is subjected. If a unit cube be considered, the forces and deformations on each face may be resolved into three components at right angles to one another, which, bearing in mind Newton's law of action and reaction, would seem to lead to a composite of nine vector components. Such a composite is known as a second-rank tensor (*see* TENSOR ANALYSIS). For reasons of symmetry, the stress and strain tensors each reduce to six independent components, and the fourth-rank elasticity tensor, which relates them to one another, reduces from $6 \times 6 = 36$ to 21 components (*see* fig.).



FROM G. W. SCOTT BLAIR AND M. REINER, "AGRICULTURAL RHEOLOGY," 1957

TRACTIONS ACTING ON A CUBE

Normal components (those at right angles to the faces) are marked σ; the shear components (those across the faces), τ

Since tensors can be treated mathematically as wholes, their use has greatly reduced the complexity of elasticity theory. Until World War II, however, most rheologists were satisfied with vectorial methods (*see* VECTOR ANALYSIS). Experiments usually involved tensions, compressions, or shears in a well-defined plane; measurements of displacements seldom had to be made in directions other than those in which the forces were applied. During the war, however, much work was done on systems which, when sheared in a concentric cylinder viscometer, for example, climb up the inner cylinder against the force of gravity. Such phenomena, generally called after K. Weissenberg, one of their principal investigators, show the presence of cross-stresses, and for their adequate study a tensorial treatment is advisable. The most striking Weissenberg phenomenon is shown by a sticky commercial product for catching rodents. Rubber solutions, many low polymers (intermediates in plastics manufacture), and sometimes sweetened condensed milk, also show the phenomenon.

The application of tensor theory to highly complex rheological systems forms an important part of rheological theory. Its most difficult applications are to relatively large deformations (often a concern of rheologists), to which the classical theory of elasticity is inapplicable; and to anisotropic materials. The latter are materials, such as wood, that show different properties according to the axis along which they are tested; many of them also change their rheological characteristics as they are strained (the strain hardening and softening shown by many plastics, mastics, and metals). A. S. Lodge has shown that the use of tensors can be avoided, but only at the cost of introducing other, more complex concepts; *e.g.*, contravariance.

High Elasticity.—The atoms of a material cannot be drawn far apart without leading to rupture of the specimen. When a coiled spring is stretched, the large extension is due to the accumulation of rotations—the turning around of the individual atoms—and not to their separation one from another. In some highly extensible elastic materials the molecules may perhaps behave like coiled springs; but it is certain that in most cases, of which rubber is typical, the elasticity is caused by quite a different mechanism. Rubber molecules consist of very long chains of carbon and hydrogen atoms, free to rotate in such a way that many different configurations are possible. When not subjected to stress, rubber has many more coiled configurations than extended ones. When a stretched rubber strand is released, molecular movements rapidly change the configurations to more probable and therefore more contracted forms. If the probability of an event is p_1 and of another event p_2, the probability of both events occurring will be $p_1 p_2$; that is, probabilities are multiplicative. For many purposes, additive properties are preferred; therefore much use is made of the logarithms of probabilities, expressed as "entropies," which are additive (*see* THERMODYNAMICS). Rubber contracts because the contracted state has a higher entropy than the stretched state, not because of any storage of potential energy by the molecules.

The shift of emphasis from energy to entropy, *i.e.*, to probabilities, in the rheology of complex systems is important (*see* HEAT: *The Nature of Heat in Matter*). E. Schrödinger (1887–1961) pointed out that the characteristic feature of life is to delay the inevitable rise of entropy which ultimately brings death. Living systems are not "closed" in the thermodynamic sense; for open systems, a new science of "irreversible thermodynamics" is being developed (L. Onsager, 1931; I. Prigogine, 1947; A. Katchalsky and O. Kedem, 1961; S. R. de Groot, 1962). This science will be needed for rheological theory when the flow properties of living matter come to be more widely studied.

Biorheology.—In the 1830s, J. L. M. Poiseuille established the laws of flow through capillary tubes of simple fluids such as water. As a medical man he was interested in the flow properties of blood, on which E. C. Bingham also later worked. The flow of blood, even in rigid artificial capillaries, is extremely complex. The corpuscles do not flow in trajectories parallel to the capillary walls; therefore Poiseuille's Law, which states that the rate of flow at a given pressure is proportional to the fourth power of the tube radius, does not hold. Such anomalies are also known for paints, clays, etc., and are called sigma phenomena. In the case of blood, it has been shown that in a given capillary the square root of the rate of flow is linear with the square root of the applied pressure (N. Casson's equation). In such a case, what is being measured is not an invariant physical property in the classical sense, but rather a characteristic change in behaviour more like the entities observed when rheological changes are studied subjectively by experts handling industrial materials. G. W. Scott Blair named such entities "quasi-properties" and showed that they play an important part in subjective quality judgments. Their mathematical treatment starts with power-equations like those of Ostwald and De Waele (*see* above), and leads to the use of fractional differential coefficients and gamma functions. Similar treatments were successfully applied by A. Graham to data for creep of complex metal alloys.

The importance of rheology to medicine has been realized in many fields besides that of hematology. The properties of uterine cervical mucus reflect the levels of sex hormones; the lubricative characteristics of synovial fluids may well be related to rheumatic conditions; the consistency of bronchial mucus affects the breathing difficulties of chronic bronchitics; etc.

RHETORIC is the name traditionally given to the use of language as an art based on a body of organized knowledge. The study of rhetoric exerted an important formative influence on European culture from ancient times to the 17th century A.D., after which it became less important. Both the nature of its influence and the reason for its decline become apparent from a study of the real character of the so-called art at various stages of its history. The techniques of rhetoric and the knowledge on which they were based were always organized to serve only some specific and limited purpose. Thus, when the purpose changed and new techniques, based on new theories, emerged, the new system was as incomplete as the old had been. The textbooks of rhetoric that men studied never covered more than a small part of the field of linguistic expression; and it was the realization of this that finally led to widespread abandonment of the effort to create an art of discourse.

Rhetoric as the Art of Oratory: Ancient Greece.—In its original form, rhetoric was the systematic study of oratory (*see* GREEK LITERATURE: *Early and Attic Prose: Rhetoric and Oratory*). It was, as Aristotle later pointed out, the art of persuasion. The first man to teach oratory was the Sicilian Corax (*q.v.*) during the spate of litigation which followed the establishment of democracy in Agrigentum and Syracuse in the 460s B.C. Another Sicilian, Gorgias (*q.v.*) of Leontini, introduced the new art—along with the idea that it could be taught—to Athens in 427 B.C., and rhetorical training, taught by the sophists (*q.v.*), rapidly became the favoured form of higher education.

This initial flowering of rhetoric in the 5th and 4th centuries B.C. was marked by important controversies, one of which concerned the use of stylistic devices. Gorgias had employed colourful epithets, antitheses, rhythm and rhyming terminations; the prevalence of antitheses can be clearly seen in Thucydides, both in the speeches and in the historical narrative, and the interest in argument in many of the plays of Euripides. The next generation saw a reaction, and the plain style of Lysias (*q.v.*) found many supporters. But the criteria by which each party sought to establish the superiority of its choice—clarity, impressiveness, decorum, beauty, purity of language—depended, except for the last, largely on subjective assessments, and so the problem of mannerism was posed but not solved. The outstanding teacher of the day, Isocrates (*q.v.*), and the outstanding orator, Demosthenes (*q.v.*), championed a compromise style between the plain and the mannered. But their example was not decisive, and at the close of the 4th century the long battle between the Atticists and the Asian mannerists was still to come.

Another dispute concerned the relationship between rhetoric and morality. It was recognized that scientific proof was not usually possible in oratory. Speeches were concerned with probabilities. They were often addressed to an uneducated or a potentially inattentive audience, and Gorgias had maintained that an orator therefore could argue the just and the unjust cause with equal force. Regarding rhetoric as an amoral instrument, he was attacked by critics who claimed that oratorical skill had an essentially moral character, since truth and justice provided the best opportunities for persuasion. This view, which Aristotle later endorsed, has much to be said in its favour at the theoretical level, but the fact that an orator's skill could often counterbalance the superior persuasiveness of a just cause remained uncontroverted, and Gorgias continued to find adherents as late as the Renaissance.

A third group of controversies concerned education. The popularity of the rhetorical schools put them in control of the intellectual development of Greece, and rhetoricians who were prepared to accept the consequent responsibility criticized those of their utilitarian colleagues who kept their eyes fixed on the needs of the law courts, and at the same time disagreed among them-

selves as to what should be added to the rhetorical course. Isocrates recommended political thought.

Plato's *Gorgias* and *Phaedrus,* and the *Antidosis* of Isocrates, deal with these controversies (for Plato's views *see* PLATO: *Gorgias*) but the best ancient Greek account of the development of the art is the *Rhetoric* of Aristotle. Aristotle limits his comments on all points to the requirements of oratory for politics, for the law courts, and for a show speech (either on a ceremonial occasion such as a public funeral or as a tour de force for rhetorical public entertainment). This, taken in conjunction with the fact that he composed a separate *Poetics,* suggests that rhetoric at this stage made no claim to be a complete "arts of discourse."

Aristotle's *Rhetoric* begins with the orator's construction of his case. First, he must assemble all the possible arguments, by examining all the "places" (*topoi,* hence "topics") where arguments can be found. Aristotle's spatial metaphor confuses rather than clarifies his meaning, but an example will show what is intended. Suppose that a political speaker is recommending some measure. He must appear to advise what is good. Happiness is universally regarded as good. So are justice, moderation, magnanimity, magnificence. These then are the speaker's "topics." If he examines each in turn, he will see which applies to the case he is handling.

When the arguments have been collected, the orator must decide which to use, and here great stress is laid on understanding the psychology of the audience. Orators must know what provokes anger, admiration, shame, and how different categories of hearers—the young, the old, the well-born—are likely to react. Syllogistic argument is rarely possible in a speech and would in any case appear too cumbersome. Rhetoric must rely on "enthymemes," incomplete syllogisms often based on probable premises ("If you, who are a bad man, admit you would not have taken a bribe, is it likely that I, a good man, would have done so?" and "Dorieus has won a race at Olympia, therefore he has won a crown" [omitting the middle term "the prize at Olympia is a crown"] are both enthymemes) and on "examples," one or more instances which lead to an inductive demonstration (*e.g.,* "Pisistratus asked for a bodyguard and so became dictator; so did Theagenes; therefore Dionysius in asking for a bodyguard is aiming at a dictatorship"). Knowledge of how an audience reacts is important because what is not strictly proof must pass as such. This is the least satisfactory section of the treatise. In stating that truth and justice provide the best arguments, Aristotle would seem to have committed himself to the opinion that the rhetorical substitutes for the syllogism had a certain validity, but he makes no systematic effort to analyze their relation to scientific proof. The work then closes with a discussion of style and the general pattern a speech should follow. Aristotle emphasizes the need for clarity, but admits that metaphors and figures of speech may be used in moderation. Considered as a whole, his survey can be seen to have many gaps which later generations were to fill (see *Traditional Rhetorical Method,* below), but its combination of practical experience with a philosophic breadth of view gave it a lasting importance.

Aristotle's generation saw the passing of the free cities with their active political life; and for the next two centuries the development of rhetoric under the Hellenistic empires was decided by the needs of the courts and the activity of the schools. It was an age of useful but unspectacular advance under the shadow of the noisy controversy between the Atticists and the Asian mannerists. The discussion of general themes, developed in the philosophy schools, proved a handy teaching device and was accepted as a regular branch of oratory. The imitation of well-known orators became a popular exercise. Hermagoras of Temnos (*c.* 150 B.C.) revolutionized the technique of constructing a case when he pointed out that there was always a key point of conflict—which might concern law, fact, or principle—and was the focus round which arguments ought to be grouped.

Rhetoric as the Art of Oratory: Rome.—The discoveries of the Hellenistic age are known through their influence on Latin oratory (*see* LATIN LITERATURE: *Rhetoric and Education*). The important achievement of Roman rhetoric was the transmission of the Greek tradition to medieval Europe. By the 2nd century B.C. republican Rome was attracting the most adventurous of the Greek teachers. But Greek rhetorical theory was not only restated in such textbooks as the anonymous *Rhetorica ad Herennium* (86–82 B.C.) or Cicero's *De inventione.* It was also applied; and speeches were produced which equaled the best work of the Athenian orators. At the same time, the career and genius of Cicero lent the study of rhetoric a dignity it had previously lacked. In his accusation of Catiline, Cicero portrayed eloquence as wielding real power in great affairs. After his time, the aims of the rhetorical education were linked in men's minds with the urbanity and versatility he had glorified.

With the advent of the empire, political and judicial oratory gradually ceased to be important in the evolution of rhetoric, for Roman autocracy, like its Hellenistic predecessors, extinguished political debate and restricted the scope of the courts. But writers of all kinds had long been using rhetorical devices, and the interest in rhetoric was not sustained by cultivated society's interest in literature. The Greek author Dionysius of Halicarnassus (fl. *c.* 20 B.C.) commented on the orators from the point of view of a literary critic. The 1st century A.D. was still a transitional period in which oratory was brought closer to literature. Quintilian's *Institutio oratoria* (*c.* A.D. 95), in spite of certain contemporary emphases, still looked to the past, giving the most complete account that exists of the art of oratory. It is therefore convenient to take from him the account of rhetorical method that was followed in classical antiquity and continued to be used in the schools.

Traditional Rhetorical Method.—The speaker is concerned with three matters: the art of rhetoric, the speech itself, and the situation that calls it forth. The first of these has five parts: collecting the material (called invention), arranging it (disposition), putting it into words (style; Latin *elocutio*), memorizing it, and finally delivering it. The second matter, the speech itself, should be divided into five: an introduction (to gain the goodwill of the audience), a statement of the point at issue, arguments to prove it, refutation of contrary arguments (this by some authorities is included under the preceding division), and a conclusion (either a recapitulation or an appeal to the audience's emotions). The third matter, which is the situation, covers the kinds of speech: whether the discussion is general (*e.g.,* "should a man marry?") or particular (*e.g.,* "should Crassus marry?") and whether it is a show speech (called demonstrative), political (called deliberative), or legal.

To return to the five parts of the art of rhetoric, the one dealing with style (the putting of the material into words) received the most space in rhetorical handbooks and is indeed regarded by the modern reader as the chief concern of rhetoric. This is justified insofar as, of the threefold aim of rhetoric, to instruct, to move, and to delight, the thing that contributes almost exclusively to delight is style.

Quintilian and most other ancient authorities teach that the chief virtues of style are four: correctness, clarity, elegance, and appropriateness. Of these, elegance receives most space as it is the easiest to teach, including as it does all the varieties of the figures of thought and of words (or syntax). (*See* FIGURES OF SPEECH.) Among the former are rhetorical questions, impersonation (whereby the speaker invents the actual words of the persons described or even of nonhuman entities such as one's country), and vivid description (whereby an event is not merely stated to have occurred but described in full imaginative detail). Figures of words (or syntax) include antithesis, parallelism of phrases, and repetition of words. Ancient rhetoric was also much concerned with the rhythms of speech, the order of words, and the length and cohesion of sentences.

Imitation of the Past.—When Quintilian wrote, a new kind of rhetoric was beginning to appear. The Roman emperors, in order to win support for the culture their state represented, had begun to subsidize the schools, in which rhetoric provided the syllabus of secondary education. Rhetoricians thus became the high priests of an official cult of the past. The following three centuries produced a mass of historical, critical, and anecdotic writing; and they also saw a determined effort to perpetuate the

language and style of the great classics. Imitation, which had hitherto played a subordinate role in rhetorical training, now became its focus, and the popular textbooks of the period, the *Progymnasmata* of Hermogenes (b. *c.* 150) of Tarsus and of Aphthonius (fl. *c.* 400), a pupil of Libanius at Antioch, make it clear that the exercises particularly studied—narrative, description, the expansion of a moral saying, prosopopoeia, and so on—were those that are found not only in oratory but in many other literary genres as well. Rhetorical study now covered a field coextensive with Greek and Latin literature; but, looked at from another point of view, its scope was narrower than before because, within this larger field, only certain writers were thought to deserve imitation.

Declamations.—The imitation of historians and poets as well as of orators played an important part in rhetorical training, and the vogue for academic declamations showed that oratory itself was admired primarily as a literary genre. Declamations were not normally concerned with contemporary life. A deliberative speech (*suasoria*) would choose a situation from the historical or legendary past: for instance, it might urge the Spartans to hold the pass of Thermopylae against the enemy, or take the part of Agamemnon and argue that he will not sacrifice his daughter Iphigenia at Aulis. Similarly, a legal speech (*controversia*) would deal with a situation that referred to some fictitious "law," such as that the man who kills a tyrant shall be rewarded; the declamation might argue that a man should receive the reward because he was the chief agent in causing the tyrant's death, even though he had not actually killed him with his own hands.

The preparation of declamations as a school exercise gave the pupil practice in getting to the heart of a problem, to the actual issue (Latin *status*) at stake, and had long been used in rhetoric. The method was to ask three questions: Did it happen (*an sit*)? What was it (*quid sit*)? Was it good or bad (*quale sit*)? Thus, in the case of tyrannicide cited above, the pupil would have to discover if the event (a killing) had taken place, how it should be defined (murder, tyrannicide, etc.), and finally, whether it was a praiseworthy or a blameworthy act. Of course in an imaginary case the answer to the first question requires not investigation of fact but plausible conjecture.

Early Middle Ages.—Christian literature adopted the imaginative approach of the imperial schools. In the Byzantine Empire, schools used the *Progymnasmata* and encouraged imitation (*see* GREEK LITERATURE: *Byzantine: Rhetoric*). In the west Augustine, who distrusted pagan models, in his *De doctrina Christiana* advised imitating the style of the Bible, though his own writings contain the stylistic devices which came naturally to him after his education in rhetoric. Cassiodorus (6th century) and Isidore of Seville (7th century) both included the traditional rhetorical scheme in their encyclopaedic treatises, counting it among the seven liberal arts as forming one of the trivium together with grammar and dialectic. Bede (d. 735) followed Augustine by showing in his short work *De schematibus ac tropis* how the Bible is not inferior to secular classical literature as a storehouse of figures of speech to imitate. Alcuin (d. 805) continued the traditional rhetorical teaching, but without excessive stress on style, in his dialogue on rhetoric and the virtues.

The disputes of the 11th century provoked a revival of judicial rhetoric which petered out when it was realized that dialectic and law provided better weapons for controversy, and a century later imitation flourished briefly at the school of Chartres. But not until 1150 was education far enough advanced for a unified rhetorical tradition to appear.

Mannerist Rhetoric in the Later Middle Ages.—The 12th century tried to build a new culture based on the theoretical knowledge at its command. In rhetoric, this knowledge was drawn principally from the *Rhetorica ad Herennium* and Cicero's *De inventione*. But the statements in these works concerning the handling of the subject matter were too closely linked with judicial oratory to be useful in an age whose main interest was in epistolary composition, and so attention centred on the sections discussing style. It was assumed that in every genre, in both prose and poetry, two sorts of writing were possible: the one plain, the other "artistic," employing figures of thought and speech. The view that figures were a source of stylistic distinction was a commonplace of classical rhetoric, but their possible functional relation to meaning had not been adequately examined. It is not surprising therefore that the 12th century accepted them as ornamental in character and came to believe that the more figures were used, the better the style. There followed a cult of mannerism, with insistence on particular rhythmic endings, and on etymologies —often fantastic—which gave a richer colour to individual words.

The Renaissance: The Revival of Imitative Rhetoric.—The obscurity of manneristic writing provoked a reaction. Petrarch reinstated the cult of the classics and popularized their imitation. Already, as early as the 11th century, Byzantium had seen a recrudescence of the Atticism which had flourished under the late Roman Empire, and its scholars had developed the instructional techniques and compiled the grammars and lexicons required for the exact reproduction of an earlier stage of Greek. The arrival of Byzantine scholars in Italy in the 15th century meant therefore that the systematization of imitative technique spread to the west. Humanist rhetoric was born, with its dictionaries, its handbooks of Latin usage and *exempla* (adages, anecdotes, and other illustrative material), and its memorizing procedures. Ultimately, it accomplished more than its Greco-Roman and Byzantine predecessors; for its imitative purpose was linked with wider ambitions. The humanists were the first to see the literature of a people in its totality as a cultural achievement. They were not content merely to write classical Latin. Desiring to equal the cultural triumphs of antiquity, they attempted every classical genre, thus giving imitation a range it had not had before. And this was also the age when the national literatures of Europe were attaining their maturity, so that imitation was no longer limited to Latin. It was practised in the vernaculars, and with striking success.

The Renaissance: Ramism.—By 1550, the humanist tradition, embodied in the rhetorical works of Erasmus (*q.v.*), had a firm grip on education, but Latin, on which that education rested, was going out of use, and the vernaculars had absorbed all they could absorb through imitation. A new approach to rhetoric was required. As early as the end of the 15th century the Dutch humanist Rodolphus Agricola recommended that writers should develop their subjects with reference to genus, species, causes, effects, similarities, opposites, and suggested 30 such headings, analogous to the "topics" of classical rhetoric. In the 16th century Petrus Ramus (Pierre La Ramée) popularized Agricola's ideas and had an enormous influence. Ramism detached invention and disposition from rhetoric (reckoning them as part of dialectic), leaving it only with style and delivery (memory having fallen into the background). Rhetoric was thus severely limited in scope by losing all concern for content (*see* RAMUS, PETRUS).

The Decline of Rhetoric.—Ramism carried the seeds of its own destruction. The dichotomy it established between thought and the words that formulated thought provoked a search for a plain style which would represent facts without adventitious verbal ornament. Rhetoric fell into discredit. Still an important school subject in the 18th century, it followed rather than led contemporary taste as is evident from the lectures of Hugh Blair, the first professor of rhetoric and belles lettres in Edinburgh University, which mirror the period's preoccupation with sensibility and the sublime. But Adam Müller's impressive *Reden über die Beredsamkeit* (1816) and Archbishop Richard Whately's *Principles of Rhetoric* (5th edition revised; 1836) were already, in the main, works of literary history. Convinced of the supreme value of experiment, the 19th century was led eventually to condemn all traditional techniques of style and all organized rhetorical study. Jacob Burckhardt described antiquity's interest in rhetoric as a "monstrous aberration." These extreme views remained popular until the 1930s, when logical positivism drew attention to the importance of studying how language is used. I. A. Richards' *Philosophy of Rhetoric* (1941) emphasized the need for a new art of discourse and substantial attempts were later made, particularly in the United States, to develop such an art in a form suitable for teaching in schools and universities.

RHEUMATIC FEVER is a generalized disease commonest in children between the ages of 5 and 15 but occurring with considerable frequency in young adults. The manifestations, severity, duration and aftereffects are highly variable. In a small percentage of patients death may occur because of inflammation of the heart in the acute attack, but in a much larger number the acute attack subsides with a variable amount of cardiac damage. Recurrences are frequent in the absence of appropriate measures for the prevention of streptococcal infection.

Causative Factors.—The exact cause of rheumatic fever was still unknown in the 1960s, although a close relationship to previous streptococcus infection had been well established. This is based on the high incidence of known streptococcus infection preceding attacks of acute rheumatic fever, the presence of streptococcal antibodies (particularly antistreptolysin) in the blood of patients with the disease, and the prevention of recurrent attacks of rheumatic fever by the continued use of drugs that prevent streptococcus infection. It is generally believed that the disease results from the reaction of the body to the streptococcus rather than the direct effect of streptococcal infection.

Many authorities believe that this illness represents a hypersensitivity reaction, although direct evidence for this view is lacking.

Clinical Characteristics.—The clinical recognition of rheumatic fever is made difficult by the wide variety of symptoms. The most important evidences are those that result from inflammation of the heart, and of these the commonest are certain types of murmurs and increased heartbeat rate. It is frequently difficult to determine whether a given murmur results from active rheumatic fever or a previous attack. With more serious heart involvement there may be rapid enlargement of the heart, heart failure resulting in difficulty in breathing, evidence of inflammation of the membranes overlying the heart (pericarditis) and irregularities of the heartbeat. Additional evidence of cardiac involvement is sometimes obtained on electrocardiographic tracings. The extent and duration of cardiac inflammation is extremely variable in all age groups, but in general tends to be severer in young children than in young adults. Severe cardiac involvement may result in death in a relatively short time.

Involvement of the joints is a common manifestation. This may vary from mild aches and pains to severe swelling, redness, tenderness and limitation of motion. Characteristically several joints are involved, with migration from day to day. The joint symptoms are commoner in older patients than in young children. Joint manifestations are commonest in the early stages and never result in permanent impairment of function.

Nodules may occur beneath the skin, but rarely before the third or fourth week of disease. The presence of nodules is usually associated with involvement of the heart. A variety of skin rashes may be present in acute rheumatic fever, the most characteristic of which is erythema marginatum, which is considered highly specific for the disease by most authorities.

Chorea (*q.v.*) represents a nervous system manifestation of rheumatic fever. It is characterized by purposeless movements of the arms and legs and inability to perform coordinated movements of muscle groups. Emotional disturbances may also be present. The severity and duration of these symptoms are highly variable.

Fever occurs early in the disease in a relatively large percentage of patients, but it is not necessarily present. A wide variety of other signs and symptoms may also occur, among them nosebleeds, weakness, abdominal pain and weight loss. Examination of the blood usually shows an increase in the rate of sedimentation of red blood cells, and frequently shows anemia and an increased number of white blood cells.

In typical cases a combination of the above symptoms makes diagnosis relatively certain. Many patients have the disease in subtler form, so that the first recognition of the previous rheumatic episode comes from the presence of structural abnormalities of the heart characteristically produced by rheumatic fever.

The length of an individual attack of acute rheumatic fever is variable and is sometimes difficult to ascertain. In certain persons symptoms may be transient, while in others the disease remains obviously active for periods of more than a year.

The degree of cardiac damage sustained during an individual attack is not related simply to the severity of the acute attack, but may be more closely related to the total duration of active disease. The interference with normal heart function, usually referred to as rheumatic heart disease, results in the main from distortion of the valve structure. Although such distortion may lead to extreme cardiac disability, patients with rheumatic heart disease may carry on relatively normal lives. The greatest threat to life is reactivation of the rheumatic process. A large percentage of people have no interference with cardiac function following recovery from acute rheumatic fever.

Pathology.—Although clinical evidences of rheumatic fever may occur in the heart, joints, skin and central nervous systems, the most characteristic pathological findings are seen in the heart. On gross examination the heart is usually dilated, and the surface may be covered by a stringy material that adheres to the membrane covering the heart (pericardium). The heart muscle is paler and softer than normal. Microscopic examination shows evidence of a peculiar type of inflammation in the connective tissue. The most characteristic microscopic lesion is the Aschoff nodule, which consists of an accumulation of large pale cells together with smaller cells surrounding degenerating connective tissue fibres. Aschoff nodules are most characteristically found in the connective tissue of various parts of the heart, but similar lesions have been identified in the connective tissue of other organs.

In later stages of the disease scar formation occurs. Such scarring results in deformity of the valves of the heart, bringing about interference with normal function. The mitral valve is most frequently involved, although the aortic valve is also commonly distorted. The tricuspid valve is rarely affected, while the pulmonary valve is almost never involved.

Treatment.—Until 1949 the usual treatment of rheumatic fever consisted of the use of salicylate drugs. There remained some difference of opinion as to whether these drugs have any specific effect on the rheumatic process. Adrenocorticotropic hormone (ACTH), cortisone and certain synthetic hormones related to cortisone have striking effects on rheumatic fever, but it is not clear whether use of these drugs prevents subsequent development of heart disease and has an advantage over salicylate treatment. Of cardinal importance in treatment is the complete eradication of any streptococcal infection, usually accomplished by large doses of penicillin.

Patients with active rheumatic fever are usually kept at bed rest for the duration of the active disease. In patients with severe cardiac failure, digitalis, mercurial diuretics, restriction of salt intake and oxygen are valuable. Adequate nutrition and good nursing care are important. The administration of prophylactic drugs (usually penicillin or sulfadiazine) has resulted in a considerable reduction in the rate of recurrences by preventing further streptococcal infection.

Surgical treatment is successfully used to relieve the narrowing of the openings of the valves of the heart. By 1958 some progress also had been made in correcting by surgical means the defect in closure of valves that occurs in rheumatic heart disease. *See also* HEART AND LUNG, SURGERY OF.

Public Health Aspects.—Rheumatic fever frequently occurs in more than one member of a family, apparently due to a hereditary susceptibility to the disease. It has been found in many parts of the world in representatives of all races. In the United

States (as measured by mortality statistics) it is commoner in the northern half of the country, the highest rates occurring in the middle Atlantic and mountain states. The observed rates cannot be correlated simply with latitude, average temperature, altitude or rainfall. The disease is not confined to any socioeconomic group, but studies indicate high mortality in low-income groups. It is difficult to estimate the true incidence because of difficulties in diagnosis and poor reporting, but there is evidence that rheumatic fever is the leading cause of death among children in the U.S.

Because of the frequently long duration of rheumatic fever, few families are able to meet the financial burden; the disease thus became an important public problem. In some large cities special hospitals are maintained for the care of children with rheumatic fever and rheumatic heart disease.

One of the earliest community attempts to meet the problem was the London County council's Rheumatism scheme, which provided for both hospital care and a follow-up program for all children with rheumatic fever. The financial difficulties in the care of rheumatic fever in Great Britain were overcome by the National Health Insurance scheme.

In the United States special programs for the care of children with rheumatic fever were developed after 1939 under the Social Security act. These programs were operated on a state basis with funds provided jointly by the states and the children's bureau of the federal department of health, education and welfare. The nature of the services and of their administration varied somewhat from state to state. The American Council on Rheumatic Fever, organized in 1944 under the American Heart association, promoted public and private programs for care, research and education. Under the National Heart act of 1948 the National Heart institute of the United States public health service began to conduct research on heart disease, including rheumatic fever. Through a program of grants-in-aid the Heart institute also supported research, training, demonstration programs and community programs for the control of rheumatic fever. Local communities also developed control programs.

RHEUMATOID ARTHRITIS: *see* Arthritis.

RHEYDT, a town of West Germany in the *Land* (state) of North Rhine-Westphalia, Federal Republic of Germany, lies 14 mi. (22 km.) SSW of Krefeld by road. Pop. (1961) 94,004. The reconstruction of the town, heavily damaged in World War II, was rapid. The civic hall (with theatre, 1930), savings bank (1955), Schmölder Park, stadium, Bellermühle swimming pool, zoological gardens and Zoppenbroich Stud are notable. Rheydt Castle (with museum) is a Renaissance building by Pasqualini (1560–70) with charming arcades in the inner court. Each September a festival with a flower procession is held. Railways connect Rheydt with Krefeld, Düsseldorf, Cologne, Aachen and the Netherlands. Principal industries are spinning and weaving and the manufacture of cotton, woolen, silk and man-made fabrics, clothing, heavy machine tools, electrical goods (motors, generators, transformers, cables), and printing materials. Rheydt received formal civic rights in 1856. In 1929–33 it was united with Mönchengladbach to form Gladbach-Rheydt but afterward incorporated Odenkirchen and Giesenkirchen-Schelsen to form a separate town.

RHIANUS (fl. *c.* 225 B.C.), Greek poet, was a Cretan and, according to the Suda lexicon, a slave who became a scholar. His only surviving works are 10 or 11 epigrams of some merit preserved in the *Greek Anthology.* He produced a recension of Homer, in which he seems to have shown good judgment, but was best known as an epic poet. His *Messeniaca* dealt with a 7th-century war between Messene and Sparta and the exploits of the Messenian hero Aristomenes, but of four other epics little more than the titles is known. All 5 extended to several books, and the *Thessalica* to 16. Evidently therefore he disregarded the call of Callimachus and Theocritus for a smaller scale in epic poetry.

See fragments and epigrams ed. by J. U. Powell, *Collectanea Alexandrina* (1925). *See* also W. Aly in Pauly-Wissowa, *Real-Encyclopädie der classischen Altertumswissenschaft,* 2nd series, vol. 1, col. 781–790 (1914).

RHINE (Ger. Rhein; French Rhin; Dutch Rijn; from Celtic *Renos,* Lat. *Rhenus*), a major European river. With a length of about 820 mi. (1,320 km.) and a catchment area exceeding 85,000 sq.mi. (220,150 sq.km.), it is culturally, historically, and economically the most important river in Europe.

Physically the Rhine can be divided into five distinct sections: the Alpine Rhine, High Rhine, Upper Rhine, Middle Rhine, and Lower Rhine. The Alpine Rhine has two principal headwaters: (1) the Vorderrhein, which issues from Lake Toma (7,691 ft. [2,344 m.]) near the Oberalp Pass and, following a northeasterly course, receives the Medelserrhein, the Glenner, and the Rabiusa; and (2) the Hinterrhein, which originates at 7,611 ft. (2,320 m.) in the Rheinwaldhorn glaciers west of the San Bernardino Pass and, after flowing northeastward through the Rheinwald, turns north to receive the Averserrhein and, below Thusis, the Albula. It unites with the Vorderrhein at Reichenau, Switz. After continuing for a short distance northeastward the Rhine turns north at Chur, where it receives the Plessur. Farther downstream it is joined by the Landquart and Ill on the right, and by the Tamina on the left. Forming sections of the Swiss-Liechtenstein and Swiss-Austrian border along an artificially straightened course, it flows through a delta in two separate branches into the Lake of Constance (*q.v.*). The lake receives as affluents the Bregenzer Ache, the Argen, and Schussen and, through the Aach, it receives water lost through underground drainage from the Danube where that river crosses the limestone of the Swabian Alb.

At Constance the river leaves the main lake and flows into the Untersee. Leaving this at Stein, the High Rhine follows as far as Basel a winding westerly course which for most of its length forms the Swiss-German border. Rapids, especially the Rheinfall (about 69 ft. [21 m.]) below Schaffhausen, render this section, like the Alpine Rhine, unsuitable for through navigation. The construction of a dam in 1891 made the lowest part of the High Rhine navigable below Rheinfelden, which became a port terminal in 1934. Seven further dams with hydroelectric stations have been built. The High Rhine receives as tributaries from the south the Thur, Töss, Aare (with Limmat and Reuss), and Birs; its only large tributary from the north is the Wutach.

At Basel, where the river turns sharply northward and enters the rift valley, the Upper Rhine begins and extends to the entrance to the Rhine gorge above Bingen. The broad valley is bounded westward by the Vosges and Hardt mountains and eastward by the Black Forest, Kraichgau, and Odenwald. Above Mannheim the Rhine is confined to a largely artificial bed.

The Upper Rhine flows past the ancient cities of Strasbourg, Speyer, Worms (of the *Nibelungenlied* fame), and Mainz, and the comparatively new ones of Kehl, Karlsruhe, Mannheim, Ludwigshafen, and Wiesbaden. Forming the Franco-German boundary from Basel almost to Karlsruhe, the Rhine receives as major tributaries in this stretch the Ill from the west and Kinzig from the east. Farther north the Upper Rhine is joined from the east by its most important tributaries, the Neckar and the Main.

The Middle Rhine, which extends from Bingen to below Bonn, is the most beautiful part, especially the southern stretch where the river is confined to a gorge separating the Hunsrück Mountains in the west from the Taunus Mountains in the east. At the entrance to the gorge the Rhine receives the Nahe from the west. Above Sankt Goarshausen on the right bank, the Lorelei cliff rises sheer to 433 ft. (132 m.). It was immortalized in Heinrich Heine's lyric, set to music by P. F. Silcher, commemorating a legend invented by Clemens Brentano. Above Coblenz, where the valley widens, it is joined from the east by the Lahn and at Coblenz by the Moselle (Mosel) from the west. Joining farther north, the Rivers Ahr from the west and the Sieg from the east are not navigable. The volcanic crags of the Siebengebirge and Drachenfels, opposite Bonn, are the last uplands to approach the river.

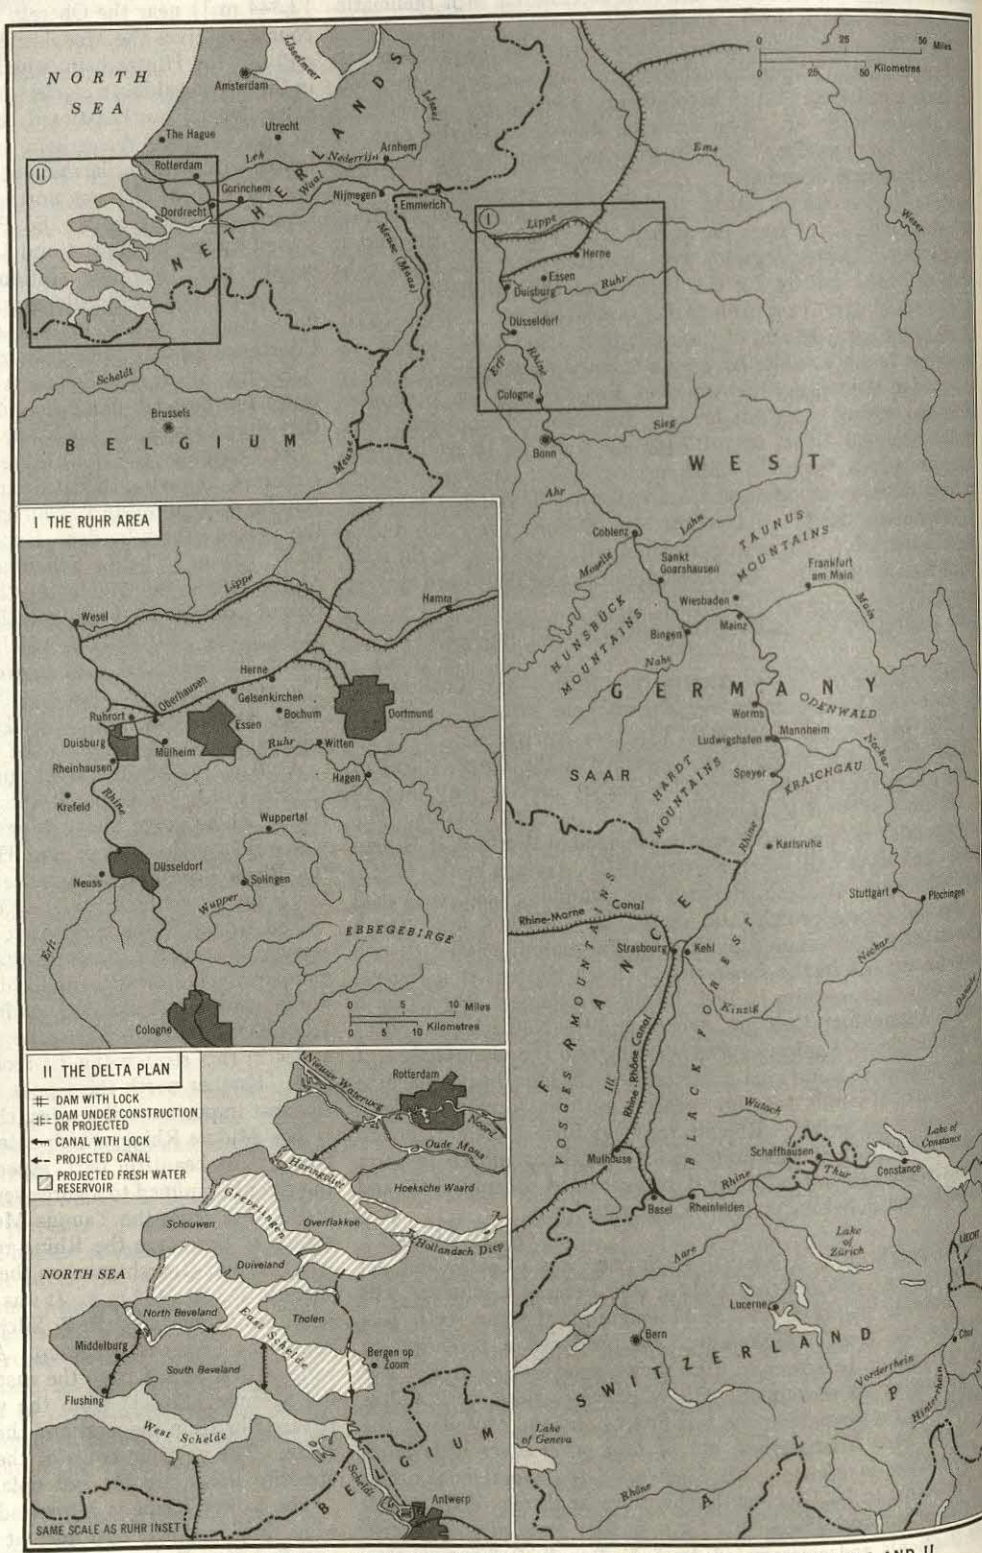
The Lower Rhine is a lowland river about 1,000 yd. (914 m.) wide, flowing slowly past ancient Cologne, fashionable Düsseldorf, and Duisburg-Ruhrort, a city of heavy industry and the leading

Rhine port. Its main tributaries thereabouts are the Erft from the west and the Ruhr and Lippe from the east. Below Emmerich the Rhine leaves Germany and after a further brief stretch in Dutch territory divides into the numerous distributaries of its delta, which mingle with those of the Meuse (Maas) and Scheldt (Schelde). The first division is into a southern branch, the Waal, and a northern, the Pannerdensche Kanaal. The Waal, which carries about two-thirds of the total flow, after skirting Nijmegen becomes known as the Merwede near Gorinchem. Below Gorinchem it sends off a branch southwestward, the Niewe Merwede, through which 55% of the combined Meuse-Rhine water reaches the sea in the Haringvliet. The Merwede itself divides at Dordrecht into the Noord (leading toward Rotterdam) and the Oude Maas, which reaches the sea through the Nieuwe Waterweg. The Pannerdensche Kanaal divides south of Arnhem into the IJssel, which takes about one-ninth of all the Rhine water into the IJsselmeer (*q.v.*), and into another branch first called Rijn, then Nederrijn and, from south of Utrecht onward, Lek. Utrecht itself lies on a distributary, the Kromme Rijn, which splits into the Vecht, leading northward, and the Oude Rijn, which reaches the sea near Leiden. In the mid-1960s weirs were constructed on the Nederrijn to increase the freshwater supply to the IJsselmeer, prevent the saltwater boundary from encroaching farther inland, and generate electricity. After being joined by the Noord, the Lek becomes the Nieuwe Maas, which below Rotterdam joins the Oude Maas, linked with the sea by an artificial channel, the Nieuwe Waterweg.

Evolution.—The ancestor of the present Rhine originated in the later Tertiary as one of the three great rivers draining the northern Alpine foredeep. This *Urrhein*, however, still lacked the High Rhine and Alpine Rhine, then part of the Danube system; it acquired them by river capture during the Quaternary.

Hydrography.—The Alpine Rhine with its steep gradient, high runoff coefficient (80% of the precipitation in its catchment area), high winter minimum, and high summer maximum, is a characteristic Alpine stream. Although variations of the regime are evened out by the Lake of Constance, which is fed by upland streams as well as by the Rhine, they are increased again by the confluence with the Aare, which on an average carries more water than the Rhine (19,800 as against 15,500 cu.ft. per sec. [561 as against 439 cu.m. per sec.]). Below this confluence, however, the tributaries from the uplands, with their spring or winter maximums, increasingly moderate the unbalance. Thus at Cologne the average deviations from mean flow are slight, and the pronounced summer maximum of the higher sections gives place to winter and summer maximums, yielding a regime favourable to navigation. Moreover, the river freezes only in exceptional winters.

The Rhine as a Waterway.—As a commercial artery, the Rhine is unrivaled among the world's rivers, historically as well as in the amount of traffic carried. The Romans maintained a Rhine fleet, and the importance of the river increased enormously with the rise of medieval trade, which relied on water transport wherever possible because of the poor roads. The rock barrier of the



THE RHINE AND ITS TRIBUTARIES. THE RUHR AREA AND DELTA PLAN ARE SHOWN IN INSETS I AND II

gorge at Bingen divided navigation into two sections: predominantly upstream traffic by seagoing vessels to Cologne, and predominantly downstream movement of transalpine commodities from Basel to Mainz and Frankfurt am Main. After about 1500 navigation declined, because of reorientation of trade toward the Atlantic and political disintegration of the Rhineland. The rise of modern navigation began in the 19th century and its present magnitude is attributable largely to three factors: removal of political restrictions on navigation; physical improvements and canalization; and increasing industrialization of the riparian countries.

The principle of free navigation on the Rhine was agreed upon by the Congress of Vienna in 1815, and was put into effect by the Mainz Convention of 1831, which also established the Central Commission of the Rhine. This first treaty was simplified and revised in the Mannheim Convention of 1868 which, with the extension in 1918 of all privileges to ships of all countries and not merely the riverain states, remains (broadly speaking) in force.

As regards physical improvements, two sections presented serious handicaps: the rock barrier at Bingen and the southern Upper Rhine. At Bingen two navigation channels were blasted out in 1830–32; canalization of the Upper Rhine by confining it within an artificial bed and straightening its course was undertaken 1817–74. In neither case were the resulting improvements entirely satisfactory; for the passage at Bingen ships always take a pilot. Navigation on the Upper Rhine, despite the shortening of its course by 51 mi. (82 km.) and further improvements made after 1907, suffers from seasonal variations of flow and the swift current.

Canalization.—Plans exist for extending navigation through the Alpine Rhine into Switzerland by canalizing the Aare system, and a Swiss-German Convention of 1929 envisaged canalization of the High Rhine between Rheinfelden and the Lake of Constance. To improve navigation and to procure hydroelectric power, France at the Treaty of Versailles obtained the right to divert Rhine water below Basel into a canal that was to rejoin the Rhine at Strasbourg. Construction of the first section of this Grand Canal d'Alsace, designed to take vessels of 1,500 tons, was completed with the building of a dam at Kembs in 1932, and greatly improved navigation. Construction was resumed after World War II, but in the treaty of 1956 France, in return for German agreement to the canalization of the Moselle, consented to terminate the canal at Neu Breisach. The remaining four of a total of eight dams are to utilize Rhine water by the construction of canal loops only.

Below Basel the Huningue branch of the Rhine-Rhône Canal leads to Mulhouse, where it meets the main arm of that waterway, which joins the Rhine at Strasbourg. The Rhine-Rhône Canal (1810–33) is navigable by 300-ton craft and carries only moderate traffic. More important, although no larger, is the Rhine-Marne Canal (1838–53), which also joins the Rhine at Strasbourg.

The Neckar is canalized through Stuttgart as far as Plochingen and the Main as far as Bamberg, both waterways being navigable by 1,350-ton craft. A treaty signed in 1956 between the Federal Republic of Germany, France, and Luxembourg provided for canalization of the Moselle from Coblenz to Thionville (170 mi. [274 km.]) for ships of 1,500 tons; this was completed in 1964. The Lahn is canalized for 200-ton craft for 42 mi. (68 km.).

In the Ruhr region, the Ruhr itself (except for the last 7 mi.) and the Lippe are not used as waterways. Their place is taken by: (1) the Rhine-Herne Canal, completed in 1916 between Duisburg and Herne, navigable by craft of 1,350 tons, linking the Rhine through the Dortmund-Ems Canal with the German coast and through the Mittelland Canal with the waterways of central and eastern Germany and eastern Europe; and (2) the less important Wesel-Datteln-Hamm Canal (1930), parallel to the lower course of the Lippe and navigable by craft of 1,350 tons. Nearer the mouth, the Merwede Canal (enlarged 1952) past Amsterdam provides another route to the sea for ships of up to 4,300 tons.

Traffic.—The decisive factor that made the Rhine a major waterway was the rise of modern industry. This necessitated the bulk movement of coal, ore, building materials, and oil, and provided transport able to compete successfully with rail and road. The first steamship to appear on the Rhine was one which in 1817 made the voyage from London to Coblenz. Basel was first reached by steamship in 1832. From 1840 onward most transport was by tugs towing barges; development since 1945 involved mainly self-propelled units, but the introduction of push tugs portended another change. By the mid-1960s the total Rhine fleet of about 7,600,000 tons consisted of roughly 16,000 craft, of which three-quarters were on passage at any given moment. Over one-half of this fleet was Dutch, nearly one-third West German, and the remainder French, Swiss, and Belgian. Regular passenger services run between Mainz and Cologne and (in summer) between Basel and Rotterdam.

Although passenger transport is substantial, the Rhine is chiefly important for its freight traffic. This rose from about 1,500,000 tons at mid-19th century to 189,300,000 tons in 1962. More than twice as much cargo moves upstream as downstream and traffic density increases rapidly downstream, the figure for the Dutch section being about 12 times that for the southern Upper Rhine. Of the commodities transported, coal, which on the German section amounts to nearly a quarter of the total, takes first place, followed by ore, building materials, and petroleum products. Other freight includes grain, lignite, and fertilizers. Although it is only 1% of the total German Rhine traffic, there exists a genuine Rhine sea traffic which, with modern motor ships, can reach Rheinfelden. A direct Basel-London cargo service was opened in 1936. Basel is also the port of registry for the Swiss merchant fleet of about 25 ships.

The Rhine in History.—The effects of rivers on the regions through which they flow tend to alternate between trends toward unifying the regions culturally and politically and making a political boundary of the river. Of this phenomenon the Rhine is a classic example. During prehistoric times the same culture groups existed on both banks; similarly, in early historic times Teutonic tribes settled on either side of its lower and Celts alongside its upper course. Bridged and crossed by Caesar in 55 and 53 B.C., the Rhine became for the first time, along its course from the Lake of Constance to its mouth at Lugdunum Batavorum (Leiden), a political boundary—that of Roman Gaul. This did not endure for long, because before the death of Augustus the provinces of Germania Superior and Germania Inferior were carved out of Gaul, and south of Bonna (Bonn) the boundary of the Roman Empire was marked by the *limes* (Roman fortified frontier) well east of the Rhine; but it was fateful because it resulted in later claims by France, esteeming itself the successor to Gaul, to the Rhine as its natural boundary. When the Roman Empire disintegrated, the Rhine was crossed along its entire length by Teutonic tribes (A.D. 406), and the river formed the central backbone of the kingdom of the Franks and the Carolingian empire. When in 843 that empire was divided, stretches of the Rhine formed the eastern boundary of the central part, Lotharingia, until 870 when the Rhine again became the central axis of a political unit, the later Holy Roman Empire. Subsequent events shifted this axis eastward and caused political disintegration along the Rhine. The Thirty Years' War ended with the final loss to Germany of the Rhine headwaters and delta area, and a gradual advance of France toward the Rhine, which it reached under Louis XIV through his acquisition of Alsace.

The French Revolutionary Wars saw further French advances, and the Treaty of Lunéville (1801) made the Rhine, along most of its course, France's eastern boundary. But France advanced beyond the Rhine and included northwest Germany within its borders, and the Confederation of the Rhine extended French control as far as the Elbe and Neisse. The resultant upsurge of German nationalism was expressed by E. M. Arndt (*q.v.*) who, in 1813, wrote: "The Rhine is Germany's river, not its boundary." Nevertheless, the Congress of Vienna left France in possession of Alsace and thus with a Rhine frontier. Ambitions of Napoleon III to acquire further Rhenish territory strongly aroused German feelings. In 1840 Max Schneckenburger wrote his patriotic poem *Die Wacht am Rhein,* which was set to music by Karl Wilhelm in 1854 and became the rousing tune of the Prussian armies in the Franco-German War of 1870–71. One result of this war was that France lost Alsace and thus its Rhine frontier. For the subsequent history of the region *see* RHINELAND. The fortified defensive

system of the Maginot Line (built 1927–36) adjoined the French bank of the Upper Rhine from the Swiss frontier to near Lauterbourg. The opposing *Westwall,* or Siegfried Line (1936–39), adjoined the German bank from the Swiss frontier to near Karlsruhe.

Events after World War II suggested that the struggle for possession of the Rhine had been superseded by a trend toward economic and even political union of the riparian states.

(K. A. S.)

RHINELAND, the historically controversial area of Western Europe lying along the Rhine (*q.v.*), east of the modern frontier between Germany on the one hand and France, Luxembourg, Belgium, and the Netherlands on the other. Apart from the strip of country from Karlsruhe southward to the Swiss frontier (west of which the Franco-German frontier is formed by the Rhine), the Rhineland extends from the northern borders of the French *départements* of Moselle and Bas-Rhin over the Saarland and the German *Land* Rhineland-Palatinate into northwestern Baden-Württemberg, western Hesse, and southwestern North Rhine-Westphalia (*qq.v.*).

Ancient History.—Julius Caesar in the 1st century B.C. thought of the Rhine as the natural frontier between the Celtic peoples of Gaul (*q.v.*) and the Germanic peoples (*q.v.*) to the east; but even in his time Germans were crossing it westward. From the 1st century A.D., under the Roman Empire, the country immediately west of the Rhine was divided between two provinces: Germania Superior, from the Alps to the vicinity of Antunnacum (Andernach), with Argentoratum (Strasbourg), Mogontiacum (Mainz), and Confluentes (Coblenz); and Germania Inferior, from Bonna (Bonn) to the Rhine estuary, with Colonia Agrippina (Cologne). Northward and westward of the former province and southward and westward of the latter, the hinterland was in the province Belgica, which included the upper and middle Moselle valley, with Augusta Treverorum (Trier). East of the Rhine, opposite Germania Superior, were the Agri Decumates (*q.v.*), a zone of defense for Gaul. From the 3rd century the Franks (*q.v.*) began gradually to occupy the Rhineland, overcoming other Germanic tribes (Chatti and Alamanni); and by the first decade of the 6th century Salian Frankish predominance was established under Clovis, founder of the Merovingian dynasty's rule over Gaul (*see* FRANCE: *History;* GERMANY: *History;* MEROVINGIANS). Under the partitions effected by the successors of Clovis the Rhineland was included in Austrasia (*q.v.*).

The early Carolingians (*q.v.*), whose power originated in Austrasia, made the Rhineland a base for their military and missionary penetration of Germany; and Aachen (*q.v.*) became the second city of the Frankish Empire of Charlemagne. In 843, however, the Treaty of Verdun divided the Frankish dominions between Charlemagne's grandsons: the emperor Lothair I received the Middle Kingdom (from the North Sea to Italy), Charles II the Bald the West Frankish Kingdom (France), and Louis the German the East Frankish (Germany, mainly east of the Rhine). When the Middle Kingdom was in turn divided (855), its Rhineland areas were included in Lotharingia, the kingdom of Lothair I's son Lothair.

The article LORRAINE describes the boundaries of Lotharingia; its partition between Charles the Bald and Louis the German under the Treaty of Mersen (870); the subsequent acquisition of the formerly West Frankish part by the Germans; and the formation of the duchies of Upper and Lower Lorraine (959). East of the two Lorraines, areas of the Rhineland belonged in the 10th century to the duchies of the "stem-lands," Saxony, Franconia, and Swabia (*qq.v.*). In the course of the following centuries, however, while Upper Lorraine was diminished, the other duchies were dissolved, and the Rhineland became the seat of numerous territorial principalities. These included: in the north, the electoral archbishopric of Cologne, with the secular territories of Cleves, Berg, and Jülich (*qq.v.*); in the central area, the electoral archbishoprics of Trier and Mainz, and the bishoprics of Worms and of Speyer, with the electoral Palatinate, the countship of Nassau, and some dependencies of Hesse (*qq.v.*); and, in the south, the bishopric of Strasbourg, with the cities and various lordships of Alsace and the margraviate of Baden, with Breisgau (*qq.v.*).

Modern Times.—Exploiting the troubles of the Reformation in Germany, France encroached on Lorraine in the 16th century; Brandenburg acquired Cleves and Mark in 1614, forming the nucleus of the future power of Prussia (*q.v.*) in the Rhineland; and the Thirty Years' War (*q.v.*) and Peace of Westphalia gave France a foothold in Alsace. Louis XIV's wars consolidated the French position on the Alsatian Rhine (*see* DUTCH WARS; GRAND ALLIANCE, WAR OF THE; SPANISH SUCCESSION, WAR OF THE), but the farther-reaching claims that Louis made through his policy of "reunions" and his attempt to annex the Palatinate were frustrated. Ducal Lorraine was not definitively incorporated in France till 1766.

The French Revolutionary and the Napoleonic Wars (*qq.v.*) transformed the situation. The whole left bank of the Rhine from the frontier of the Batavian Republic to that of the Helvetic was ceded to France by the Treaty of Lunéville in 1801; and a radical reorganization of the right bank was effected by the *Reichsdeputationshauptschluss* of 1803 before further changes followed the establishment of the Confederation of the Rhine (1806). In 1810 the French frontier was extended from the Rhine at Wesel northeastward to the Baltic Sea at Lübeck. (*See* GERMANY: *History.*)

After Napoleon's downfall the Congress of Vienna (1814–15) limited France's frontier on the Rhine to the Alsatian zone again, opposite Grand-Ducal Baden. North of Alsace a new Palatinate was constituted for Bavaria. Northwest of the Palatinate were some little exclaves of other German states, namely Saxe-Coburg's Lichtenberg, Oldenburg's Birkenfeld, and Hesse-Homburg's Meisenheim; but north of these the whole left bank as far as Cleves, together with Jülich and Aachen in the west and Trier and Saarlouis in the south, became Prussian. This Prussian territory was united with Prussia's adjacent possessions on the right bank to form the Rhine Province (Rheinprovinz) in 1824. To the southeast of the Rhine Province lay Nassau (on the right bank) and part of Grand-Ducal Hesse (Darmstadt on the right bank, Mainz and Worms, north of the Palatinate, on the left). Prussia purchased Lichtenberg in 1834 and annexed Nassau and Meisenheim after the Seven Weeks' War of 1866. Alsace-Lorraine (*q.v.*), ceded by France after the Franco-German War of 1870–71, was organized as a condominium of the states of the new German Empire. The Rhineland became the most prosperous area of Germany, the Prussian north in particular being highly industrialized.

The 20th Century.—After World War I the Treaty of Versailles (*q.v.*) not only restored Alsace-Lorraine to France but also went some way toward satisfying France's desire for a farther barrier against the danger of German invasion. Great Britain and the United States objected on ethnic grounds to the French demand for the permanent detachment of the left bank of the Rhine from Germany; but the treaty stipulated that Allied troops should occupy it, with large right-bank bridgeheads opposite Cologne, Coblenz, and Mainz (including Wiesbaden), and at Kehl. Belgian troops were to occupy a zone from Aachen northward, British troops a zone round Cologne, U.S. troops a zone round Coblenz, and French troops a zone round Mainz. Occupation might last 15 years from Jan. 10, 1920; but if Germany fulfilled the other obligations of the treaty, in particular with regard to reparations (*q.v.*), a northern zone might be evacuated after 5 years only and a central zone after 10, before the final evacuation of the south. The German left bank, however, and a right-bank strip 50 km. deep were to be permanently demilitarized. An Inter-Allied Control Commission (set up by a separate arrangement in 1919) was to provide for the security of the occupying forces but was not to interfere with the German civil administration. It should, however, erect a customs barrier to protect the area's economy.

Great Britain and the U.S. inclined to lenience, the French and the Belgians to severity. Appealing to the largely Catholic population's anti-Prussian feeling and to fear of Communism, the French also sponsored separatist movements. Hans Dorten's attempt

to create a Rhineland state within the German Republic (1920) came to nothing, partly because the Germans resented his dealings with Gen. Charles Mangin, head of the French occupying forces, partly because the British and the Americans did not support it. In spring 1920, however, when the German government sent troops into the demilitarized Ruhr district to suppress a Communist insurrection, the French temporarily seized Frankfurt am Main, Homburg, and Darmstadt on the right bank (April–May); and in March 1921 the French, the British, and the Belgians occupied Duisburg, Ruhrort, and Düsseldorf, the so-called Sanctions districts in the Ruhr area, on the ground of German default on reparations. The U.S., however, which had not ratified the Versailles Treaty, made a separate peace with Germany in August 1921 and began withdrawing troops from the Rhineland in 1922.

The Franco-Belgian occupation of the rest of the Ruhr (*q.v.*) in January 1923 on the one hand precipitated the completion of the U.S. withdrawal (whereupon the Coblenz zone was taken over by the French), and on the other revived the separatist movements. A "Rhineland Republic," proclaimed at Aachen on October 21, lasted till November 2; and a separatist coup in the Palatinate led to fighting before the British induced the French to disavow it. In 1924 France agreed to the evacuation of the Ruhr and to the Dawes Plan on reparations (*q.v.*); but the evacuation, scheduled for January 1925, was postponed till August.

Thanks largely to the diplomacy of the German statesman Gustav Stresemann (*q.v.*), the Pact of Locarno (*q.v.*), which covered not only the Rhineland but also Eastern Europe, was signed in London on Dec. 1, 1925. With France's consent, the northern two-thirds of the Belgian and British zones were evacuated by Jan. 31, 1926. The Inter-Allied Control Commission was replaced by a commission of the League of Nations.

In response to diplomatic pressure from Germany (which had moreover to pay the occupation costs), France agreed to a reduction of troops in the Rhineland to 60,000, but still insisted on occupation pending the due payment of reparations. An interview between Stresemann and the French statesman Aristide Briand at Thoiry in September 1926 came to nothing, and Stresemann's raising the question of "war guilt" caused France to fear a German repudiation of the Versailles Treaty. By 1929, when the Young Committee met to revise the Dawes Plan, it was understood that if financial agreement could be reached, complete evacuation of the Rhineland should ensue. Great Britain and Belgium announced that they would withdraw their troops before the end of the year, and France had to be content with referring difficulties to arbitration and with postponing total evacuation only till Germany's acceptance of the Young Plan. On June 30, 1930, five years before the date fixed in 1919, the last occupying troops left the Rhineland.

The Franco-Soviet five-year treaty of mutual guarantee (May 2, 1935) was declared by Nazi Germany to be a violation of the Locarno agreement. While the French Senate was still debating ratification of the treaty, Hitler on March 7, 1936, repudiated the Rhineland clauses of Versailles and Locarno and announced that German troops had entered the demilitarized zone. Unaware that Hitler had instructed his troops to retreat if the French invaded, the French general staff refused to act unless partial mobilization were ordered, which the French cabinet refused. Only a few specialized units were sent up to the Maginot Line along the French frontier, while the other Locarno Powers and the League of Nations were invited to take cognizance of the situation.

Of the Locarno Powers, Great Britain did nothing because the British public regarded the Rhineland as German territory; Belgium was too weak to act; Italy secretly approved Germany's move; only Poland and Czechoslovakia were ready to stand by France. Protracted negotiations failed to undo the German remilitarization of the Rhineland, and the passive attitude of the Western Powers foreshadowed their acquiescence to Hitler's annexation of Austria and to his demands on Czechoslovakia in 1938. Had the Western Powers reacted strongly, World War II might have been averted.

RHINELAND-PALATINATE (RHEINLAND-PFALZ), a *Land* (state) of the Federal Republic of Germany constituted in 1946 from the southern part of the Prussian Rhine province, the Bavarian Palatinate, and part of Rhine-Hesse and of Hesse-Nassau. It is bounded north by North Rhine-Westphalia (Nordrhein-Westfalen), east by Hesse and Baden-Württemberg, west by Belgium and Luxembourg, and south by Saarland and France. Area 7,657 sq.mi. (19,832 sq.km.). Pop. (1961) 3,417,116.

The northern portion covers the southwest section of the Rhine Plateau. This includes the Eifel (*q.v.*) and farther south the Hunsrück, which slopes northward to the Moselle (Mosel) Valley. The deeply entrenched meanders of the Moselle, extending from Trier downstream to the Rhine confluence at Coblenz, are covered with vineyards on the south-facing slopes, with woods on the steep north-facing slopes and patches of arable land on the valley floor. A closely settled lowland between Mayen and Coblenz contains volcanic materials which are used for building. East of the Rhine gorge on the lower Westerwald Plateau lies Montabaur, the centre of an old-established ceramics industry. South of the Hunsrück is lower terrain with woods, arable land, and many small villages. The Haardt, or Pfälzer Wald, is a wooded sandstone plateau whose low hills overlooking the Rhine support important vineyards and orchards. This southern portion of the *Land*, known as the Palatinate, has a number of industrial towns such as Pirmasens. Ludwigshafen dominates the Palatinate, and its chemical industry along the left bank of the Rhine employs more than 30,000 workers, many from the large villages in the Rhine plain.

The *Land* is divided into the administrative divisions of Coblenz, Trier, Montabaur, Rheinhessen, and Pfalz (Palatinate). The principal towns are Ludwigshafen, Mainz (the capital), Kaiserslautern, Trier, Coblenz, Worms, and Pirmasens (*qq.v.*). About 58% of the people are Roman Catholics and 41% are Protestants. According to the constitution, primary schools in Rhineland-Palatinate are confessional (or have confessional religious instruction), as are the five teachers' training colleges. Establishments for higher education include the Johannes Gutenberg University at Mainz and a technical college for administration in Speyer.

Forestry and farming are the staple occupations. Much of the farming is arable, grain crops in particular (wheat, rye, and oats) being grown, as well as potatoes and sugar beets. The warmth of the river valleys allows tobacco to be grown; but far more important are the vineyards along the Rhine and its westbank tributaries, the Moselle, Nahe, and smaller rivers. Rhineland-Palatinate contains more than two-thirds of the whole area devoted to vines in the Federal Republic and has by far the greatest wine production per acre. Although the *Land* is primarily agricultural, industry is of importance in the economy. Ludwigshafen is an important river port and its major industries include metalworking and papermaking as well as the production of chemicals. Other industries include footwear (Pirmasens) and sewing machines and bicycles (Kaiserslautern). Tourists also bring in much revenue. For history, *see* HESSE; PALATINATE; RHINELAND.

RHINITIS: *see* NOSE, DISEASES OF.

RHINOCEROS, a large, hoofed mammal characterized by one or two horns on the face. Rhinoceroses, along with tapirs and horses, belong to the order Perissodactyla, all members of which have an odd number of toes. The family Rhinocerotidae contains five extant, and many extinct, species. Those now existing have been greatly reduced in number since the mid-19th century, and are in danger of extermination.

The animal is large, massively built, with a long, barrel-shaped body and comparatively short legs. The skin is extremely thick and tough, and the coarse hair is sparse, almost lacking in some species. The horn has a fibrous structure and is an outgrowth of the skin; it has no core of bone, though the skull is thicker at the base of the horn. The horns are used as weapons, though there can be few occasions when their use is actually required in defense —except against man—for no other animal predator is powerful enough to overcome a healthy adult rhinoceros. The rhinoceros'

eyesight appears not to be acute, but its senses of hearing and smell are highly developed.

All species of rhinoceros are vegetarians; some browse on leaves and buds of shrubs or small trees, others graze on grasses and other herbage. The Asiatic species stay near water or mud holes in which to wallow; some species prefer prairie, while others stay mostly in bushland or forest. Rhinoceroses are usually solitary, but a calf may accompany its mother for a long time, even after the birth of a younger sibling. A single calf is born after a lengthy gestation (16 months in the Indian rhinoceros), and the horns are at first represented by mere thickenings of the skin. The longevity of the Indian rhinoceros is almost 50 years.

CAMERA PRESS—PIX FROM PUBLIX

AFRICAN BLACK RHINOCEROS (DICEROS BICORNIS)

In spite of their size, rhinoceroses are generally placid, inoffensive creatures. The black rhinoceros, however, has a reputation for unprovoked attack because it may panic and charge blindly at a strange object such as a man when disturbed. The flesh of rhinoceroses is relished by some African tribes. The skin was used for making sjamboks, the whips used in the days of the ox wagons. Horns of all species are greatly prized in the Far East, where the powdered product is believed to be a powerful aphrodisiac.

In former geologic periods rhinoceroses inhabited both the Eastern and Western Hemispheres but are now restricted to tropical Africa and Asia. The Indian (*Rhinoceros unicornis*) and the Javan (*R. sondaicus*) species resemble each other in having the skin thrown into deep folds on the shoulders and thighs and round the neck and in possessing only one horn. The Indian is much the larger, standing over 6 ft. at the shoulder and reaching a length of more than 14 ft. The skin of the sides and upper limbs is studded with large rounded knobs. This species was once widely spread throughout India but is now greatly restricted to certain areas in Nepal and Assam. The Javan species, considerably smaller, has less voluminous skin folds, a much shorter horn (generally absent in the female), and the skin not decorated with knobs but divided into scalelike polygonal divisions. The ears have a hairy fringe and the tail is hairy below and at the tip. This species, once widely distributed in southeast Asia, is now greatly restricted.

The Sumatran rhinoceros (*Dicerorhinus sumatrensis*) is the only Asiatic species with two horns. It is rather larger than the Javan rhinoceros. There are folds of skin on the forequarters only, and the rough skin is covered very sparsely with short black hair. Its range coincides with that of the Javan rhinoceros, and, although its numbers are reduced, it has not been brought so near extermination as the Javan species.

Both species of African rhinoceros have two horns and no skin folds. The widespread black rhinoceros (*Diceros bicornis*), with a hooked prehensile upper lip, is a browser; the larger white rhinoceros (*Ceratotherium simus*), with a blunter upper lip, is a grazer. The latter species is, among land mammals, second only to the elephant in size; it is restricted to reserves in Zululand, Uganda, and the Congo. *See* PERISSODACTYL; *see* also references under "Rhinoceros" in the Index. (L. H. M.)

RHINTHON (fl. *c.* 300 B.C.), Greek comic dramatist, is described in the Suda lexicon as an inhabitant of Tarentum (southern Italy), a contemporary of Ptolemy I, and founder of *hilarotragoedia* ("cheerful tragedy"; *i.e.*, burlesque?), otherwise called *phlyakographia*, of which he wrote 38 pieces, all now lost save for a few fragments. The poetess Nossis of Locri in southern Italy speaks of him as a Syracusan, famed for his "tragic *phlyakes*." Stephanus Byzantinus says that he gave a comic twist to tragic themes. Athenaeus mentions *phlyakes* as the name given by some, including the Italians, to the performers of a widespread type of mime or farce. Some of the nine extant titles of Rhinthon's plays suggest that he parodied Euripides. Aelius Donatus includes *Rhinthonica* in a list of types of Latin drama. To judge by the meagre remains, the literary *phlyakes* were on a higher level than the clownish performances illustrated on many 4th-century B.C. southern Italian vases.

RHODE ISLAND, a North Atlantic state of the United States, belonging to the New England group, is bounded north and east by Massachusetts, south by the Atlantic ocean and west by Connecticut. Rhode Island, official name "the State of Rhode Island and Providence Plantations" (see *History*, below), is the smallest state in the union, having an extreme length, north and south, of 44 mi., an extreme width, east and west, of 35 mi. and a total area of 1,214 sq.mi., of which 156 sq.mi. are inland water area. The capital is at Providence (*q.v.*). Rhode Island was one of the original 13 states. Its state song is "Rhode Island," the official state tree is the red maple and the official state bird is the Rhode Island Red. The origin of the name has been variously traced to a corruption of the Dutch words for "red island," a name supposedly given to the island in Narragansett bay by the Dutch navigator Adriaen Block, and to the Florentine Giovanni da Verrazano, who is said to have called it after the Island of Rhodes. The island referred to is Aquidneck on which Newport stands.

PHYSICAL GEOGRAPHY

Physical Features.—Rhode Island lies between approximately 41° 9′ and 42° 3′ N. and 71° 8′ and 71° 53′ W. The region of which it is a part was at one time worn down to a gently rolling plain near sea level, but has since been uplifted and somewhat dissected by stream action. As a result the topography is characterized by low rounded hills but is nowhere mountainous. Since the uplift and stream dissection a slight depression has allowed the sea to invade the lower portions of the river valleys, forming bays such as Narragansett bay, Providence "river" and Sakonnet "river." Glaciation has disturbed the river systems.

The mean elevation for the entire state is 200 ft., the lowest portions occurring along the ocean and the shore of Narragansett bay. The upper bay region is composed of gently rolling lands, but about two-thirds of the state consists of higher ground which begins abruptly just west of Providence and rises toward the northwest where Jerimoth hill, 812 ft., is the highest point within the state. The coast line, including the shores of the bays and islands, is extensive; its western portion is only slightly indented, but its eastern portion is deeply indented by Narragansett bay, a body of water varying in width from 3 to 12 mi. and extending inland for about 28 mi. Within Narragansett bay are numerous islands characteristic of an area that has suffered comparatively recent depression, the largest being Rhode Island (or Aquidneck), Conanicut Island and Prudence Island. Of these the most important is Rhode Island, 15 mi. long and 3 mi. wide. About 10 mi. offshore and south of the central part of the state is Block Island.

The rivers are short and of no great volume, but they flow swiftly and are useful in supplying water for industry. The Providence river is really an arm of Narragansett bay, into which flow the waters of the Pawtuxet and Blackstone rivers. The latter stream has a fall of about 50 ft. at Pawtucket, and the Pawtuxet also has a number of falls along its course. Mount Hope bay is a northeastern arm of Narragansett bay and is also the estuary of the Taunton river. The Sakonnet river is a long bay separating Aquidneck or Rhode Island from the mainland on the east. The Pawcatuck river forms part of the boundary between Rhode Island and Connecticut.

Climate.—Rhode Island has a more moderate climate than that of the northern sections of New England. There are no great ex-

tremes of either heat or cold. Narragansett Pier has a mean annual temperature of 50° F. (10° C.), a mean summer temperature (for June, July and August) of 68° and a mean winter temperature (for December, January and February) of 30°. The mean annual temperature at Providence is 50.5°; the mean for the summer, 70.1°; and for the winter, 30.2°; while the highest and lowest temperatures ever recorded are respectively 102° and −17°. The mean annual precipitation is about 38.68 in.

Soil.—As in most of New England, the soil in Rhode Island is for the most part sterile. Its quality improves, generally, from west to east. Almost half of the state is covered by an acidic sandy loam derived from the weathering of the underground rocks. Because of its rocky subsoil it drains very thoroughly, and in times of drought may become too dry even for pasturage. Very little of it has been cultivated and for the most part it supports a growth of stunted woodland. The best soil is found farther east on the rolling hills of the Narragansett basin: a firm, brown glacial type. Near Warwick and across the bay in East Providence a sandy loam, while loose and porous, occurs for the most part at low enough elevations to ensure sufficient moisture, and it has proved well suited to market gardening. About 8% of the state is covered by either a thin, coarse, sandy soil supporting scrubby pine and grass or by swamp.

Vegetation.—The flora is surprisingly rich. About 60 species of trees are native to the state, among them ash, oak, birch, hickory, poplar, pine and maple. Where the long inlet of Narragansett bay moderates the climate more southerly species such as the tulip tree flourish, while northern types such as the paper birch and sugar maple are found in the northwest. The sand plains, rocks and tidal pools along the coast support a wide variety of seaweeds, ferns and mosses. The swamps have a particularly interesting flora, which includes the insectivorous sundew and pitcher plant and several kinds of orchids. Some of the most beautiful wildflowers occur in the wooded areas—among them violet, trillium, columbine, rhododendron and mountain laurel—and the meadows are often covered with daisies and wild carrots and, in the autumn, goldenrods and asters. Wild blackberries are abundant on the sandy soil in the western part of the state.

Animal Life.—A maritime state with a long and, for much of its length, protected coast line, Rhode Island boasts an extensive representation of marine invertebrates, among them the sea anemone, sea cucumber, jellyfish, several types of marine worms, crustaceans such as the barnacle, lobster and crab, and the squid, clam and oyster. The quahog, a highly-prized hard-shelled clam, is protected by law. Both the coastal waters and the inland ponds and streams contain a variety of fish. Cod, perch and alewives are common and sea bass, bluefish and swordfish are often caught off Block Island. Inland species include perch, bass, pickerel and trout. There are many types of turtles, salamanders and frogs and nearly 20 species of snakes. Rhode Island lies at the edge of the migration route for a number of types of shore birds. In the uncultivated western portions of the state the blue jay, ruffed grouse, barred and screech owls live the year around, while the catbird, flicker and robin are common during the summer. The osprey is frequently seen in the vicinity of Touisset, and pheasants are abundant, especially in Newport county. A number of small mammals inhabit the woodlands, including foxes, rabbits, woodchucks and skunks.

State Parks and Historic Sites.—Approximately 17 state parks and beaches and 28 roadside groves are maintained by the division of parks and recreation of the state department of natural resources. Recreation facilities, both public and private, are liberally provided in the state, and Newport and Narragansett Pier in particular have long been noted as summer resorts.

Rhode Island's long and colourful history has left its cities and towns dotted with monuments, buildings, ancient graveyards and other points of interest which vividly recall the past. The home of Gen. Nathanael Greene of American Revolution fame is located in Coventry and the birthplace of the painter Gilbert Stuart in North Kingstown. Bishop George Berkeley, the philosopher, lived at Whitehall in Middletown during his stay in the colony. The village of Wickford contains a number of well-preserved 18th-century houses, among them the Stephen Cooper house (1728) and the John Updike house (1745). Other historic sites include the grave of Elizabeth Alden, daughter of John Alden and Priscilla Mullins, in Little Compton and Acote's hill in Gloucester which figured in Dorr's rebellion. *See* also NEWPORT; PROVIDENCE: *Historic Sites*.

HISTORY

Rhode Island was founded by refugees from Massachusetts who went there in search of religious and political freedom. The first settlements were made at Providence by Roger Williams (*q.v.*) in June 1636 and at Portsmouth on the island of Aquidneck (Rhode Island) by the Antinomians William Coddington (1601–78), John Clarke (1609–76) and Anne Hutchinson (*c.* 1600–1643) in March–April 1638. Becoming dissatisfied with conditions at Portsmouth, Coddington and Clarke moved a few miles farther south in April 1639 and established a settlement at Newport. In a similar manner Warwick was founded in Jan. 1643 by seceders from Providence under the leadership of Samuel Gorton. The union of Portsmouth and Newport, March 12, 1640, was followed by the consolidation of all four settlements, May 19, 1647, under a patent of March 14, 1644, issued by the parliamentary board of commissioners for plantations. The particularistic sentiment was still strong, however, and in 1651 the union split into two confederations: one including the mainland towns, Providence and Warwick; and the other the island towns, Portsmouth and Newport. A reunion was effected in 1654 by Roger Williams and a charter secured from Charles II on July 8, 1663.

In the patent of 1644 the entire colony was called Providence Plantations. On March 13, 1644, the Portsmouth-Newport general court changed the name of the island from Aquidneck to the Isle of Rhodes or Rhode Island. The official designation for the province as a whole in the charter of 1663, therefore, was Rhode Island and Providence Plantations. Block Island was admitted to the colony in 1664. The charter was suspended at the beginning of Sir Edmund Andros' regime in 1686, but was restored again after the "glorious Revolution" of 1688 in England. The closing years of the 17th century were characterized by a gradual transition from agricultural to commercial activities. Newport became a centre of piracy, privateering and smuggling as well as legitimate commerce.

The passage of the Sugar act, April 5, 1764, and the steps taken by the British government to enforce the Navigation acts seriously affected Rhode Island's trade. On June 9, 1772, the "Gaspee," a British vessel sent to enforce the acts of trade and navigation, ran aground in Narragansett bay and was burned to the water's edge by a party of men from Providence. In 1776 Gen. William Howe sent a detachment of his army under Gen. Henry Clinton to seize Newport as a base of operations for reducing New England, and the city was occupied by the British on Dec. 8. To capture

this British garrison, later increased to 6,000 men, a combined operation of about 10,000 men (mostly New England militia) under Maj. Gen. John Sullivan and a French fleet carrying 4,000 French regulars under Count d'Estaing, was planned in the summer of 1778. On Aug. 9 Sullivan crossed to the north end of the island of Rhode Island, but as the French were disembarking on Conanicut Island, Lord Howe arrived with the British fleet. D'Estaing hastily re-embarked his troops and sailed out to meet Howe. After two days of maneuvering the hostile fleets were dispersed by a severe storm. On the 20th D'Estaing returned to the port with his fleet badly crippled, only to announce that he should sail to Boston to refit. The American officers protested in vain, and on the 30th the Americans, learning of the approach of Lord Howe's fleet with 5,000 troops under Clinton, decided to abandon the island. The British evacuated Newport Oct. 25, 1779, and the French fleet was stationed there in 1780–81.

BY COURTESY OF BROWN UNIVERSITY, PROVIDENCE

FIRST BAPTIST MEETINGHOUSE, PROVIDENCE, COMPLETED IN 1775 TO HOUSE THE BAPTIST CHURCH OF AMERICA, FOUNDED BY ROGER WILLIAMS IN 1639

Rhode Island's association with the other colonies, particularly its New England neighbours, was characterized by individualistic tendencies. It had been one of the first colonies to advocate and to put into practice religious freedom. Throughout its early history, not only did it refuse to give up its independence by joining Massachusetts but, as noted, there was even some difficulty in keeping the colony itself united. Under the Articles of Confederation it was principally Rhode Island that defeated the proposal to authorize congress to levy an import duty of 5% to meet the debts of the central government. When the Constitutional Convention met in Philadelphia in 1787 the Rhode Island farmers and merchants, fearing that a more centralized system of government would interfere with their local privileges, refused to send delegates. Not until the federal government threatened to sever commercial relations between the United States and Rhode Island did the latter, in May 1790, ratify the new constitution, and then by only two votes.

At the end of the American Revolution, instead of providing itself with a new state constitution, Rhode Island continued to be governed under the charter of 1663. This charter and the franchise law of 1724 had established substantial equality of representation among the towns and also restricted the suffrage to freeholders and their eldest male heirs. Drastic changes were beginning to take place in the state's economy and population, however. Agriculture and commerce declined in relative importance as Rhode Island became one of the most completely industrialized among the states. The population, which had been increasing since 1800, began an accelerated expansion about 1840 and quadrupled between then and 1900. The bulk of this increase, which continued into the 20th century, was accounted for by successive waves of immigration, beginning with the Irish in the second quarter of the 19th century. The French Canadians arrived shortly after the Irish; the Italians around 1900; and numerous other national groups in the next two decades. In addition, the population shifted from approximately 20% urban and 80% rural in 1800 to nearly 90% urban in 1900.

Demands for a more equitable representation of the urban communities in the legislature and for an extension of the suffrage to nonproperty owners precipitated the first of a long series of struggles for constitutional reform, Dorr's rebellion of 1841–42. About 1840 Thomas W. Dorr (1805–54), a young Providence lawyer, began a systematic campaign for reform. A convention summoned without any authority from the legislature and elected on the principle of universal manhood suffrage met at Providence from Oct. 4 to Nov. 18, 1841, and drafted a document which came to be known as the People's constitution. A second convention met on the call of the legislature in Feb. 1842 and adopted the Freeman's constitution. On being submitted to popular vote (Dec. 27, 28 and 29, 1841) the former was ratified by a large majority; the latter was rejected (March 21, 22 and 23, 1842) by 676 votes. At an election held on April 18, 1842, Dorr was chosen governor. The supreme court of the state and U.S. Pres. John Tyler both refused to recognize the validity of the People's constitution, whereupon Dorr and a few of his more zealous adherents decided to organize a rebellion. They were easily repulsed in an attack upon the Providence town arsenal. Dorr, after a brief period of exile in Connecticut, was convicted of high treason, April 26, 1844, and sentenced to life imprisonment. He was released by act of the assembly in June 1845 and restored to the rights and privileges of citizenship in May 1851.

The Freeman's constitution, modified by another convention held at Newport and East Greenwich from Sept. 12 to Nov. 5, 1842, was finally adopted by popular vote, Nov. 21–23, 1842. Only a partial concession was made to the demand for reform. The suffrage was extended to nonfreeholders, but only to those of American birth, so that naturalized citizens could vote only if they held property. The charter legislature was replaced by one comprising a senate, to which each town was to send one representative, and a house of representatives of 72 members, apportioned by population. In the lower house, however, each town was to have at least one representative and no city or town more than one-sixth of the total, and the small towns were left in a dominant position.

After the American Civil War agitation for further reform was renewed. Under the leadership of Charles E. Gorman, himself naturalized, a prolonged campaign was waged to secure the same voting rights for naturalized as for native-born citizens. The constitution was finally amended in 1888 to eliminate all property restrictions but one: only property owners were allowed to vote for members of city councils. This limitation was finally removed in 1928.

It was not until 1909 that further change was made in the apportionment of legislative seats. In that year an amendment to the constitution increased the number of seats in the lower house to 100 and raised the allowable limit for any one city or town to one-quarter. The status of the senate was unchanged. Providence illustrates the inequities that remained in representation. With well over one-third of the state's population in 1910 and 1920, the city was entitled to only one-quarter of the house seats and to one seat in the senate. In 1928 a further change in legislative apportionment was made as a result of which Providence was able to return five senators and Pawtucket two, with the other cities and towns continuing to send one each.

Throughout most of its history Rhode Island has tended to cast its presidential vote for the more conservative party—the Federalists, then the Whigs and, following the American Civil War, the Republicans, until Alfred E. Smith carried the state in 1928. The Democrats continued to receive the state's electoral votes from 1932 through 1948. Rhode Island returned temporarily to the Republican fold in 1952 and 1956, but voted Democratic again in 1960 and 1964 by enormous margins. National Republican allegiance was matched in its congressional representation as well as on the state level from the post-Civil War period until 1932 when it became predominantly Democratic.

An important result of Rhode Island's adherence first to the Republican party and then to the Democratic during their periods of national ascendancy was the prominence thus given to Rhode Island's representation in the councils of the nation—a prominence at times far out of proportion to its size and population. These

long periods of one-party dominance made possible the building up of seniority in congress toward positions of national leadership. U.S. Sen. Nelson W. Aldrich (served 1881–1911), backed by a highly-disciplined Republican state organization under his lieutenant, the "blind boss" Gen. Charles R. Brayton, was one of the foremost architects of American tariff policy. Aldrich was so influential nationally that he came to be referred to as the "general manager of the United States." Democratic U.S. Sen. Theodore Francis Green, who was first elected in 1936 and served continuously until his retirement in 1960, rose to the chairmanship of the powerful senate foreign relations committee.

GOVERNMENT

The Freeman's constitution of 1842, frequently amended, remained the basic law of Rhode Island until the state's first unlimited constitutional convention in 122 years was called by referendum in 1964. At the same time, the voters elected 100 delegates to the convention. Leading proposals for changes in the constitution included reapportionment of the state legislature, elimination of a $300 limit on the legislators' annual pay, extension of the governor's term from two to four years, giving the governor an item veto for the state budget, bracketing of candidates for governor and lieutenant governor on the election ballot, appointive instead of elective status for secretary of state and treasurer, and appointment of the supreme court by the governor with senate approval instead of election by the legislature. Another proposal was for the provision of a state lottery. In the meantime, a special census was taken, as of Oct. 1, 1965, to form the basis of a temporary reapportionment.

Throughout much of the state's history the legislature possessed most of the governmental power. The governor did not even have the veto until 1909, and until 1935 he had little control over the administrative agencies of the state government or over appointments to these agencies. The members of the state supreme court were (and remained) removable by vote of the legislature. In 1935 Democratic Governor Green, acting with the first Democratic majority in both houses of the legislature in many years, brought about a complete reorganization of the state administration. Administrative control was centralized in the hands of the governor through the consolidation of approximately 80 independent boards and commissions into 11 departments whose heads were appointed by him. This reform, for the first time, made the governorship a full-time position and gave the governor, in effect, the major responsibility for state policy.

The executive officers of the state government are the governor, lieutenant governor, secretary of state, attorney general and general treasurer, each elected for two-year terms in even-numbered years. Each of the latter three is in charge of the department of state government corresponding to his title. Eleven additional departments are responsible to the governor: executive, administration, education, social welfare, labour, public works, natural resources, health, business regulation, employment security, and state library services. Two of the original departments set up in 1935, finance and civil service, were combined in 1951 into the department of administration. The object of this merger was to bring together in one agency all the services needed to operate the other agencies of government, while at the same time keeping the total structure under the close control of the governor.

The legislative branch consists of a two-house general assembly made up of a 50-member senate, presided over by the lieutenant governor, and a 100-member house of representatives. The judicial branch is headed by a supreme court consisting of a chief justice and four associate justices, all elected by the legislature; a superior court with appellate jurisdiction and original jurisdiction in certain cases, consisting of a presiding justice and ten associate justices appointed by the governor with the consent of the senate; a family court of five judges; and 12 district courts.

Government at the local level is carried on by the 8 cities—Providence, Pawtucket, Cranston, Warwick, Woonsocket, East Providence, Newport and Central Falls—and 31 towns into which the state is divided. The state is also divided into five counties,

ROBERT FINKELSTEIN

BUSINESS DISTRICT OF PROVIDENCE, SHOWING THE INDUSTRIAL TRUST BUILDING AT LEFT

but the Rhode Island county is not a governmental unit as such, and it is the cities and towns which provide the usual services that are the normal responsibility of local government.

Finance.—Property taxes represent the primary source of revenue for the cities and towns. The major sources of income to the state government, in addition to federal grants, are a state sales tax and taxes on motor fuel, cigarettes and corporations. The post-World War II period saw rapidly increasing state expenditures and, hence, corresponding demands for more revenue. State expenditures almost trebled in the post-mid-century decade.

POPULATION

The population of Rhode Island in 1790 was 68,825; in 1840, 108,830; in 1880, 276,531; in 1910, 542,610; in 1950, 791,896;

and in 1960, 859,488. According to a special census in 1965 it was 892,709. The population per square mile in 1960 was 812 as compared with 749 in 1950 and with 50.5 for the U.S. in 1960.

The two most important long-term trends in the state's population have been rapid urbanization and the great impact of immigration. The urban area of the state dropped from 91.6% in 1940 to 84.3% in 1950, partly because the census definition was changed to include the suburban fringe but excluded the outlying portions of several towns formerly classed as urban under a special rule. In 1960 the urban population was 742,897, or 86.4% of the total. The state contains a portion of the Providence-Pawtucket standard metropolitan statistical area. The area within Rhode Island had a population of 731,358 or 85.1% of the total population of the state in 1960.

As elsewhere in the United States, the post-World War II years in Rhode Island brought a movement to the suburbs. This meant a flow of population out of densely settled cities such as Providence and Central Falls to residential cities and towns nearer the fringe of the urbanized areas such as Cranston, Warwick and Barrington. For example, the population of Providence fell from 253,504 in 1940 to 248,674 in 1950 and 207,498 in 1960. Warwick, on the other hand, went from 28,757 in 1940 to 43,028 in 1950 and 68,504 in 1960.

The foreign-born white population in 1880 was 73,831, or 26.7% of the total. The number of foreign born in the population reached its peak in 1910 when 178,025, or 32.8% of the total, were listed in this category. Both the number and percentage decreased from then on. In 1960, out of a total population of 859,488 the state had 539,804 inhabitants 21 years of age and older. The total population in 1960 comprised 754,216 native white, 84,667 foreign-born white and 20,605 non-white, practically all Negro. Of the foreign-born white population 12,321 were born in England, Scotland or Wales, 5,216 in Ireland, 18,438 in Italy and 18,072 in Canada (largely French Canada). There are smaller totals for Portugal, Russia, Poland and other countries.

There were 96.4 males per 100 females in 1960; 10.4% of the population was 65 years of age and older; and 57.3% of the population 14 years of age and older was in the labour force. Of the total number of employed males, 1.6% were engaged in agriculture, 8.1% in construction, 38.4% in manufacturing and 20.4% in transportation and trade.

EDUCATION

The public-school system was established in 1800, abolished in 1803 and re-established in 1828. A state board of education (provided for in a 1951 act of the general assembly) exercises policy-making power over educational programs in the state and controls the state department of education. A commissioner of education is responsible for the administration of the department's functions under the jurisdiction of the board. Each city and town has a school committee elected by the people and independent of the town or city council.

School attendance is compulsory between the ages of 7 and 16. The total public-school enrollment is approximately 150,000; about 60,000 are enrolled in private schools.

VIEW OF BROWN UNIVERSITY CAMPUS: (LEFT) MANNING HALL, 1834; (RIGHT) UNIVERSITY HALL, 1770, THE ORIGINAL COLLEGE EDIFICE

The institutions of higher education supported by the state are the University of Rhode Island at Kingston and Rhode Island College at Providence, both administered by the board of trustees of state colleges. The University of Rhode Island, a land-grant institution, was chartered in 1892 as Rhode Island College of Agriculture and Mechanic Arts. The name was changed to Rhode Island State college in 1909 and the institution became a university in 1951. It includes colleges of arts and sciences, agriculture, business administration, engineering, home economics and pharmacy and a school of nursing. The division of university extension is located at Providence. The university maintains a computation laboratory and the Narragansett marine laboratory. There is a graduate school of arts and sciences, a graduate school of library sciences and one of oceanography.

The Rhode Island College of Education was established in 1920 as the successor of the Rhode Island Normal school which opened in 1854; the name was changed to Rhode Island college in 1960. The oldest institution of higher learning in the state is Brown university at Providence, chartered in 1764 as Rhode Island college (*see* also PROVIDENCE). Other colleges in the state are the Rhode Island School of Design (founded 1877; nonsectarian) and Providence college (1917; Roman Catholic), both at Providence, Salve Regina college (1947; Roman Catholic), for women, at Newport and Barrington college (1900; non-sectarian) at Barrington.

HEALTH AND WELFARE

As in most states, these functions are shared by the state and local governments in Rhode Island. Two state administrative departments are involved: the department of health and the department of social welfare. The functions of the former have been grouped under four general headings: (1) the recording of vital statistics, regulation of professions active in the health area, etc.; (2) personal health services, including chronic disease control, maternal and child care and programs for crippled children; (3) local health services, involving co-operation with the communities of the state on health problems; and (4) environmental health services, such as food and drug control and the state laboratories. The department of health was authorized to take over all local city and town health departments as of July 1, 1966.

The small size of Rhode Island has made possible a high degree of centralization of the institutions relating to welfare services. The department of social welfare's division of curative services operates an institute of mental health and general hospital at Howard which together form the Rhode Island medical centre, the Ladd school for mentally retarded children, the Zambarano memorial hospital and other related health and welfare services. The division of correctional services maintains the male and female correctional institutions, a training school for boys and one for girls. The division of community services administers programs for old-age assistance and aid to the disabled, to dependent children and the blind and general public assistance, which is handled co-operatively with local governments. The combined health and welfare services of the two departments discussed above account for one-quarter to one-third of the state's total annual expenditures.

THE ECONOMY

Agriculture.—Rhode Island ranks low in the list of agricultural states, chiefly because of its small area, density of population and the nature of its soil. As has been generally true throughout the United States, there has been a decline in farm acreage and number of farms in the state. Within 30 years from 1935 acreage declined from 380,000 to 125,000, and number of farms from 4,327 to fewer than 1,500. Nearly two-thirds of farm income represents the value of livestock and related products—dairy products, eggs, chickens and turkeys—while the remainder represents crop value. The most important crops are hay, corn, potatoes, five principal commercial vegetables, apples and peaches.

Industry.—Throughout its history Rhode Island has had to depend on sources of income other than agriculture. Before the growth of manufacturing this meant reliance chiefly on the activities of merchants and shipowners. In the period preceding the

American Revolution molasses was virtually the cornerstone of the colony's economy. Rhode Island ships carried cargoes of locally produced cheese, fish, lumber and similar products to ports in the West Indies and returned laden with molasses which was exchanged for English-manufactured goods or distilled into rum, a valuable item of commerce. Some idea of the significance of rum in the prerevolutionary economy of Rhode Island can be gained from the fact that in 1764 there were more than 30 distilleries in the colony. Some of the product of this early manufacturing enterprise was bartered for slaves in Africa. The acute concern felt in Rhode Island over regulation of colonial commerce by the British government and the state's later reluctance to join the newly established government under the constitution are closely related to this early growth of a commercial and mercantile economy.

The beginnings of manufacturing activity other than shipbuilding and the production of rum may be said to date from the formation of a company at Providence in 1786 to spin cotton. A factory containing a spinning jenny of 28 spindles (the first machine of its kind to be used in the United States) was put into operation the following year. This factory also included a carding machine, and the fly shuttle was first introduced at Providence in 1788. In 1790 a factory was established at Pawtucket equipped with Arkwright machines constructed by Samuel Slater, an immigrant from England. These machines were operated by water power and they marked the beginning of the factory system in Rhode Island. The first power loom used in the United States was set up at Peacedale in 1814. During the rest of the 19th century and into the early 20th century textile manufacturing grew to become the major employer of labour in the state. Another industry which came to occupy an important place in the state's economy was jewelry manufacture, begun in Providence in 1784 and greatly promoted ten years later by Nehemiah Dodge's invention of the process of gold filling. Rhode Island's water power was the only natural resource in the state which contributed to this growth of manufacturing enterprise.

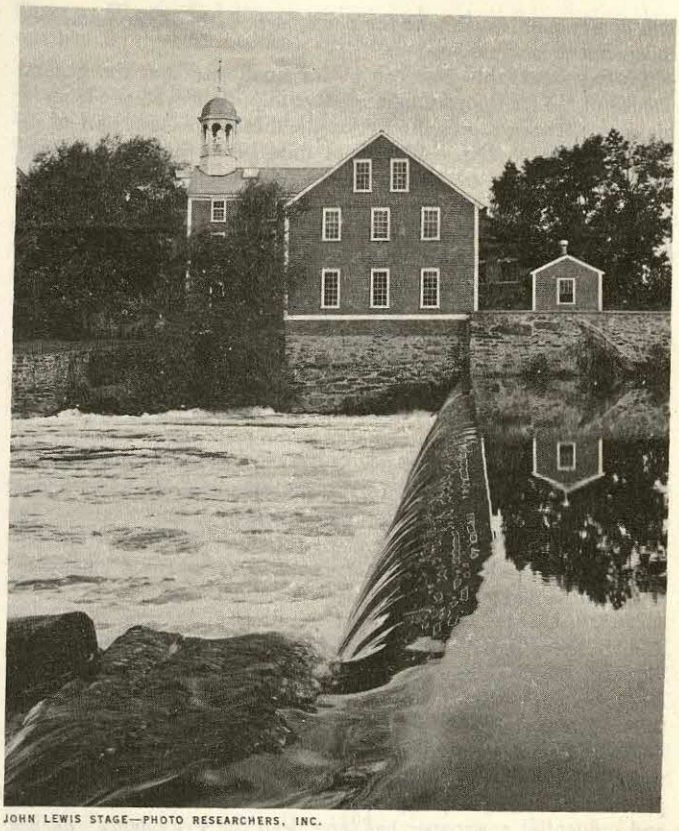
The most important industries are textiles (including cotton and woolen worsted), metals and machinery, jewelry, apparel, rubber and plastic products and optical instruments. Textiles, however, have declined in both absolute and relative importance. For example, just before World War II there were 907,000 cotton spindles in the state; 15 years later this number had fallen to 475,000.

Trends after mid-20th century showed that manufacturing employment had declined steadily while government, construction, trade, finance and services increased. In the face of this trend, the Rhode Island Development council was created by law in 1953 to encourage industrial expansion and a number of financial inducements to new industry were provided.

Mining.—The only minerals of value produced in significant quantities in the state are sand and gravel, stone and graphite. Sand and gravel accounted for almost three fourths of the value of mineral products. With the state's population density, this extractive industry raises difficult regulatory problems.

Fisheries.—Whaling was early an established industry in Rhode Island. As late as 1846 about 50 whaling vessels sailed annually from Rhode Island ports; but by the close of the century the industry had become practically extinct. In the second half of the 20th century Rhode Island ranked third among the New England states in number of persons engaged, investment and yield of its fisheries. Almost half of the total value of fishery products was accounted for by shellfish.

Trade and Finance.—As already indicated, prior to the growth of industry, Rhode Island's economy was heavily dependent on trade and commerce with neighbouring states and overseas. Until the American Revolution, Newport was the primary centre of this activity. The British occupation of the city during the war, however, spelled the end of Newport's supremacy and Providence, at the head of Narragansett bay, rapidly overtook the former and has remained the commercial centre of the state and adjacent areas. During the early 19th century patterns of commerce changed. Instead of being carried on for its own sake, shipping and commercial activity became adjuncts to the burgeoning factory economy of the state. Cargoes landed at Providence were now mainly



JOHN LEWIS STAGE—PHOTO RESEARCHERS, INC.

THE SECOND SLATER MILL (1793) ON THE BANKS OF THE BLACKSTONE RIVER IN PAWTUCKET

coal, cotton, lumber, cobblestones and other materials consumed directly or indirectly in manufacturing. Coal is an example: as steam supplanted water power in the mills, coal imports grew rapidly. About 200,000 tons were landed at Providence in 1856, and by 1878 the total approached 1,000,000 tons. In the 20th century petroleum products replaced coal as a major item of seaborne commerce.

Trade in the more localized sense grew along with the population and wealth of the state. By the beginning of the 19th century wholesale and retail enterprise had become differentiated in Providence, whereas in an earlier and simpler era no such distinction was made. Retail establishments became more elaborate and numerous. The Arcade in Providence, built in 1828 to house shops fronting on a common covered thoroughfare, typified this development, and is still in use by Providence merchants. In the 20th century, in Rhode Island as elsewhere, the small shop was replaced by the chain store, the department store and the suburban shopping centre, all of which owe their existence in large part to the development of more elaborate modes of organization and to new merchandising and packaging techniques.

The year 1791, which saw the chartering of the Providence bank, was a major landmark in the history of banking in the state. Until that date the state had no such institutions largely because the state government itself, through its issue of paper currency, performed many of the functions of a private banking system. Once the federal constitution, which prohibited the states from issuing paper money, had been ratified, banks became essential. About 12 or more additional banks had been chartered by 1810, and 43 filed reports in 1825. In 1856–57, 98 reported, the largest number in Rhode Island history. Bank services during the 19th century were provided by numerous small local banks and failures were not uncommon. The first savings banks in the state came into existence in 1819. Around the turn of the 20th century a trend toward consolidation of many of the small banks into fewer large institutions became pronounced. This trend had progressed to the point, by mid-20th century, that the state had less than ten savings banks and only a slightly larger number of commercial banks. The latter in particular developed an ever-expanding sys-

tem of branches which take the place, as it were, of the numerous independent local institutions.

Transportation.—Because of its small size and the general decline of rail transportation in relative importance, Rhode Island's highway network represents by far the most important part of its transportation system. While rail mileage in the state has declined from 211 in 1920 to about 150, total highway mileage exceeds 4,000. Approximately 20% of the over-all total comprises the state highway system, the remainder being under the jurisdiction of the cities and towns. State expenditures for highway construction and reconstruction, including federal grants, more than doubled between 1955–57 and continued to rise thereafter. Included in the highway-building program is a system of limited-access divided highways linking with similar road systems in neighbouring Connecticut and Massachusetts, plus expressways to route traffic through the congested Providence metropolitan area.

Most of the state's water-borne commerce passes through the port of Providence. By far the largest proportion of the tonnage handled there is accounted for by petroleum products. Foreign commerce amounted to more than one-sixth of the total, the remainder comprising coastwise and internal shipments. Numerous sheltered harbours around Narragansett bay are used chiefly by fishing boats and pleasure craft.

Communications.—The first printing press was set up in Rhode Island in 1727 by James Franklin, brother of Benjamin Franklin. He published the first newspaper in the colony, the *Rhode Island Gazette*, in 1732. Other newspapers were started in the 18th century, including the *Newport Mercury* by James Franklin, Jr., and the first foreign-language paper printed in the state, which appeared in 1780, issued by the French who were in Newport with Count Jean Baptiste Rochambeau. The most famous and influential newspaper has long been the *Providence Journal*, which was started as a semiweekly in 1820 and appeared daily from 1829. The owners of the *Journal* began publishing the *Evening Bulletin* in 1863 in response to the demand for news of the American Civil War, and started the *Sunday Journal* in 1885. Of the newspapers published in the state, the *Journal* and *Bulletin*, have a state-wide readership. There are a half dozen other dailies in various local communities, and about a dozen weeklies.

Among the radio stations in operation, the oldest began broadcasting in June 1922, two others were established in the 1920s and the remaining dozen or so date from after World War II. This total includes both AM and FM outlets, with some stations combining both. The state's first television channel began transmitting programs from Providence in 1949.

(E. E. Co.)

RHODES, CECIL JOHN (1853–1902), British-born South African statesman, financier, founder of the Rhodes Scholarships at Oxford, and one of the great empire builders of the late 19th century. The territories of Rhodesia took their name from Rhodes, and it was mainly through his efforts that the area now covered by Bechuanaland, Southern Rhodesia, Zambia, and Malawi came under British dominion.

RADIO TIMES HULTON PICTURE LIBRARY

CECIL RHODES

Rhodes was born at Bishop's Stortford, Hertfordshire, on July 5, 1853, the fifth son of the vicar there, Rev. F. W. Rhodes, and was educated at the parish school. In 1869, threatened with tuberculosis, he went to Natal to join his brother Herbert, who was attempting to grow cotton in the Umkomanzi Valley. Cecil landed at Durban in September 1870. Their first crop failed, but they made a profit on the second. In 1871 Cecil was left in charge while Herbert went to prospect at the newly discovered diamond fields in Griqualand West. Cecil joined Herbert at the diggings that year, and they abandoned cotton farming in 1872.

On arriving at Kimberley, Cecil managed Herbert's three claims alone, while his brother settled affairs in Natal. He became seriously ill, and when Herbert returned they took a long journey to the Transvaal interior. This helped to restore Cecil's health and made a lasting impression on him, giving him his first experience of the interior and helping to mold the future pattern of his life. After their return, Herbert Rhodes left Kimberley (1873).

Oxford.—Cecil Rhodes stayed on to gain a rapid success in the diamond mines, but in spite of his growing influence he spent much of the next few years as an undergraduate at Oxford. He matriculated in 1873, and went to Oriel College. In 1874, however, a severe illness affected his heart and lungs. Given six months to live, he went back to Kimberley. He recovered and returned to Oxford in 1876. He took his B.A. degree in 1881.

Although not a hard-working student, what Rhodes read he thought over deeply. He became convinced that the Anglo-Saxon race was the highest point of evolution in fulfillment of a divine plan and that his aim must be to help secure its predominance. Hence his preoccupation with British expansion, particularly in Africa, and with making money for the power he felt was necessary if his big ideas were to be carried out.

He wrote his first will in 1877, making the colonial secretary a trustee, and leaving his fortune (yet unmade) to form a society to extend the British Empire throughout the world, to recover the U.S., to inaugurate colonial representation in the imperial Parliament at Westminster, and to found a power great enough to make wars impossible. These ideas, modified in his five later wills (the last made in 1899), remained the driving force of his life.

Kimberley and Diamonds.—Even during his Oxford career, Rhodes had been building his fortune at the diamond mines. He had formed a partnership with C. D. Rudd in 1873, and they had secured a lucrative contract to pump out the flooded Kimberley, Dutoitspan, and De Beers mines in 1874. Assisted by Alfred Beit (*q.v.*), a brilliant financier, they began accumulating claims, particularly in De Beers Old Rush, by purchase or amalgamation with other claim holders. In 1880 Rhodes, by then the biggest claim-holder in De Beers Old Rush, floated the De Beers Mining Company. By 1887 the company was sole owner of the De Beers mines.

and his only significant rival for control of the diamond industry was Barney Barnato (*see* BARNATO, BARNETT), the main owner in the Kimberley Mine. Rhodes, given a £1,000,000 guarantee by Rothschilds, was victorious in the ensuing race to increase production and buy up shares. Finally Barnato acknowledged defeat in 1888 and sold his Kimberley mine for £5,338,650 to Rhodes, who formed the new De Beers Consolidated Mines, Ltd. Rhodes also acquired the Dutoitspan and Bultfontein mines in 1888 and the newly discovered Wesselton mine in 1891, thus securing control of all South African diamond production—90% of the world total. He had also invested in the newly discovered gold mines of the Transvaal after 1886 and had formed the powerful Gold Fields of South Africa Company in 1887. On his insistence the terms of incorporation of both the De Beers and Consolidated Gold Fields companies were framed to allow them to finance northward expansion.

Politics and Northward Expansion.—Meanwhile, Rhodes was advancing his political career. He entered the Cape Parliament in 1881 as member for Barkly West, a rural, predominantly Dutch constituency, which he kept throughout his career. He soon gained influence in Parliament, and from the first he was concerned with the north, already dreaming of British expansion to the great lakes. He urged vainly that the imperial government, not the weak Cape government, should be responsible for Basutoland, where war had broken out in 1880. While on a Basutoland commission he met Gen. Charles G. Gordon, who tried unsuccessfully to persuade Rhodes to leave South Africa and work with him.

His next concern was Bechuanaland, of vital importance to his aims because it commanded the route to the Zambezi River via the trading road from the Cape to the interior, known as the "Missionaries' road." The establishment of two small republics, Stellaland and Goshen, settled from the Transvaal, threatened to block this route, which had been placed outside the Transvaal boundary by the Pretoria Convention (1881). Rhodes succeeded in having a boundary commission to Bechuanaland set up in 1882, and he himself became a member. In Stellaland in 1882 he obtained an offer from a local chief to cede his territory to the Cape Colony, and also a petition from Stellalanders for Cape annexation. But he could not persuade the Cape government to take action, despite rumours that the republics might be incorporated with the Transvaal. However, both the imperial and Cape governments saw the force of Rhodes's arguments when Germany established a protectorate over Namaqualand-Damaraland (1883–84), making possible an east-west link between the Germans and the Transvaal which could block British expansion from the Cape. The London Convention (February 1884) finally excluded Stellaland and Goshen from the Transvaal, and the Cape government promised to help finance a protectorate over Bechuanaland. The imperial government sent a deputy commissioner to the area, the Rev. John Mackenzie, who tactlessly offended the Boers in Stellaland and Goshen and ignored their interests. Rhodes demanded that the Cape government, not the "imperial factor," should annex southern Bechuanaland and was sent to replace Mackenzie in July 1884. He successfully conciliated the Stellalanders, mainly by guaranteeing their land titles. But he was unable to prevent the Transvaal president, Paul Kruger, from declaring a protectorate over Goshen, enlarged by systematic raiding. Rhodes could do nothing and returned to the Cape demanding imperial intervention. Both the Cape and the imperial governments protested, Sir Charles Warren was dispatched with an expeditionary force to restore order, and Kruger withdrew. At the conference at Fourteen Streams in February 1885 Rhodes met Kruger for the first time but failed to establish a friendly contact, because the president distrusted Rhodes's aims. Kruger remained the greatest obstacle to Rhodes's dream of federation of South African states within the British Empire.

Rhodes soon quarreled with Warren and resigned his post of deputy commissioner in March 1885. But the high commissioner, Sir Hercules Robinson, sympathized with his aims, and in September 1885 southern Bechuanaland became a crown colony, and the north, up to the 22nd parallel, was declared a protectorate. It was not until 1895 that British Bechuanaland was annexed to the Cape, as Rhodes had always wished, and part of the protectorate was handed over to Rhodes's British South Africa Company.

In 1887 it seemed that Rhodes's plan for northward expansion might again be jeopardized by the Transvaal, which was negotiating with Lobengula, chief of the Matabele, who controlled Mashonaland and Matabeleland. To secure British influence there, Rhodes persuaded the high commissioner to make a treaty of friendship with Lobengula, who agreed to make treaties with other powers only with British consent (February 1888). But since neither the Cape nor the imperial government was prepared to take over the territory, Rhodes determined to do so himself. His agents obtained the Rudd concession from Lobengula, which gave Rhodes a prospecting monopoly in Mashonaland, rumoured to be rich in gold. This was the basis of the British South Africa Company's charter, granted in 1889, after Rhodes had amalgamated with rival concessionaires and had gained widespread support in England.

The company secured control of the area of present-day Southern Rhodesia by 1893, but Rhodes's dream extended beyond the Zambezi. In 1891 he made an agreement with the imperial government whereby a British protectorate was established over Nyasaland (the company contributing £10,000 annually for its upkeep, and Rhodes privately giving a further £10,000), while the rest of central Africa north of the Zambezi to Lake Tanganyika was administered by the company. A foreign office official and friend of Rhodes, Sir Harry Johnston, was both imperial commissioner and the company's administrator in Nyasaland until 1895, when the company assumed direct administration of the area of Northern Rhodesia. Despite Rhodes's efforts to secure Nyasaland also for the company—his strong pressure on Johnston amounted almost to blackmail—the British treasury took full responsibility for Nyasaland after 1894.

Prime Minister.—Rhodes became prime minister of the Cape in 1890. His main support came from J. H. Hofmeyr (*q.v.*) and the Afrikander Bond, which had been won over to Rhodes's schemes of northward expansion under the British flag partly by the Transvaal's refusal to allow a rail link with Johannesburg until 1892, and its high duties on Cape products, partly by Rhodes's express policy of conciliating Afrikaner opinion. Rhodes's frank aim was to unite English and Dutch interests. His premiership was important in the development of local politics and education, the advancement of agriculture, and the steps taken in native policy. The Franchise and Ballot Act of 1892 restricted the vote to men who could write and earn a labourer's wage, removing the abuses of the tribal African "blanket" vote. In native policy Rhodes wanted to introduce measures of local self-government and education and to replace tribal land tenure by individual tenure. His policy was applied in the controversial Glen-Grey Act of 1894. He took a personal interest in agriculture, encouraging scientific methods of farming, and developing the railways to link the rural districts to most of the large towns. Rhodes also increased the Cape Colony's territory by his annexation of Pondoland in 1894.

Until 1895 Rhodes waited patiently for economic pressure and encirclement to force the Transvaal into a South African federation, led from the Cape, but President Kruger was intransigent. In January 1895 he trebled the rates on the Transvaal section of the Cape-Johannesburg Railway, and when Cape traders attempted to transport goods by ox wagon instead, he closed the Vaal drifts (fords). This clear infringement of the London Convention stimulated protests from Rhodes and the high commissioner, and Kruger climbed down (October 1895). Kruger had also infuriated Rhodes by a speech of January 1895, when he had made very friendly references to Germany. Rhodes was at the height of his power. He was unopposed in the Cape and controlled the De Beers and Consolidated Gold Fields companies, with their huge resources, and the British South Africa Company. Frustrated by Kruger, he decided to take a short cut to federation via revolution.

Early in 1895 he became the directing spirit in a conspiracy to overthrow the Transvaal government by an *Uitlander* rising in Johannesburg supported by a force of the British South Africa Company led by his friend L. S. Jameson (*q.v.*). Rhodes arranged

that his friend Sir Hercules Robinson should again be sent to South Africa as high commissioner early in 1895. He secured a strip of the Bechuanaland protectorate, ostensibly as a railway, but actually as a base for Jameson's incursion into the Transvaal. On Dec. 29, 1895, Jameson made his famous raid, despite frantic messages urging postponement and assurances that the Johannesburg rising would not take place.

The fiasco of the raid was disastrous for Rhodes. Openly implicated in the scheme, he resigned the premiership in January 1896. He lost the support of the Bond, which was horrified that Rhodes had conspired against a friendly neighbour while prime minister. He was censured by the committees of inquiry into the raid held by the Cape Parliament (1896) and the British House of Commons (1897).

The Matabele rising of March 1896 kept Rhodes from brooding on his downfall. He had temporarily lost his seat on the board of the British South Africa Company, but he went to Rhodesia as a private individual and negotiated the peace terms with the Matabele (August–October 1896). He supervised the extension of railways in Rhodesia and arranged for a rail link from Salisbury to Lake Tanganyika to further his scheme for a Cape to Cairo railway. He also concluded arrangements for a Trans-African telegraph to pass through German East Africa to Egypt. He died at Muizenberg, Cape Colony, on March 26, 1902, and was buried in the Matopo Hills, near Bulawayo, Southern Rhodesia.

Rhodes was not a great orator, but he was able to express his large ideas in popular phrases, and many of his expressions—"British dominion from the Cape to Cairo," "painting the map red," "the imperial factor," "philanthropy plus 5%"—gained common usage. He combined an almost visionary zeal for British expansion with a frank belief that money was power and that one could always deal rather than quarrel with an opponent. He gained the fervent loyalty and friendship of some of his most outstanding contemporaries, but toward the end of his career he became autocratic, imperious, and surrounded by sycophants.

Rhodes Scholarships.—In his will Rhodes provided for the maintenance at Oxford University of men from specified areas overseas. The value of each scholarship eventually rose to £900 a year, for two years in the first instance, and for a third year should the trustees so decide in individual cases.

In his will Rhodes mentioned the objects he had in view in founding the scholarships:

> 1. Colonial. I consider that the education of young colonists at one of the universities in the United Kingdom is of great advantage to them for giving breadth to their views, for their instruction in life and manners, and for instilling into their minds the advantage to the colonies as well as to the United Kingdom of the retention of the unity of the empire.
>
> 2. United States. I also desire to encourage and foster an appreciation of the advantages which I implicitly believe will result from the union of the English-speaking people throughout the world. . . .

He defines as follows the principles on which he wished his scholars to be selected:

> My desire being that the students who shall be elected to the scholarships shall not be merely bookworms, I direct that in the election of a student to a scholarship regard shall be had to (1) his literary and scholastic attainments; (2) his fondness for and success in manly outdoor sports. . . ; (3) his qualities of manhood, truth, courage, devotion to duty, sympathy for and protection of the weak, kindliness, unselfishness and fellowship; and (4) his exhibition during school days of moral force of character and of instincts to lead and to take an interest in his schoolmates, for those latter attributes will be likely in after life to guide him to esteem the performance of public duties as his highest aim.

Subject to ratification by the eight trustees, the nomination of scholars is in the hands of local committees, which are appointed by the trustees, and on which former Rhodes scholars sit, but never preside. Candidates must be citizens of the country which they are to represent, with at least five years' domicile, and unmarried; and they must have passed their 19th and not have passed their 25th birthday by Oct. 1 of the year for which they are elected. Candidates are judged on their records and after a personal interview with the election committee. Save in certain exceptional cases, candidates are obliged to have attended a recognized degree-granting college or university for two years at least. At Oxford the scholars are distributed, as Rhodes desired, among all the colleges of the university, as far as possible in accordance with their own wishes; but acceptance of any scholar is determined by the colleges themselves. RHODES (Gr. RODOS), the name of the most easterly island of the Aegean Sea, separated by about 10 mi. at its northernmost tip from the Turkish coast, and the name of the island's capital. The area of the island is 540 sq.mi. (1,398 sq.km.). Pop. (1961) 63,951; population of the capital 27,393. Rhodes city is the capital since 1955 of the Greek *nomos* (department) of the Dodecanese.

The island is traversed from north to south by a mountain range reaching 3,986 ft. (1,215 m.) at the highest peak, Attavyros. It commands a view of the elevated coast of Asia Minor toward the north, and of the archipelago, studded with its numerous islands, in the northwest; in the southwest Mt. Ida in Crete is sometimes visible on clear days. The rest of the island is occupied in great part by ranges of moderately high hills, on which are extensive woods of ancient pines, greatly thinned during the Turkish era.

In addition to a fine climate Rhodes has a fertile soil and produces a variety of the finest fruits and vegetables. Around the villages are extensive cultivated fields and orchards containing fig, pomegranate, and orange trees. On the sloping hills, carob trees and others grow abundantly; the vine also holds its place and produces a wine which was highly valued by the ancients, though it seems to have degenerated greatly in modern times; a strong red wine is still exported. The valleys afford rich pastures, and the plains produce a wide variety of grain.

Under Turkish rule Rhodes was a distributing centre for European manufactures to the neighbouring islands and mainland, receiving cattle, foodstuffs, and other produce in return. Under Italian rule its commercial position became uncertain and was further disturbed by World War II. But a serious attempt was later made to restore its prosperity, especially by encouraging the tourist trade.

History of the Island.—Minoan remains at Ialysos are evidence of early Cretan influence but with the collapse of Crete (c. 1400 B.C.) the island became a powerful, independent kingdom with its own distinctive Late Bronze Age culture. According to Homer the cities of Lindos (Lindus), Ialysos, and Camiros were occupied by Heraclidae (*q.v.*), and in historic times Rhodes was occupied by a Dorian population, coming mainly from Argos, after the Dorian invasion of Greece. Lindos, Ialysos, and Camiros belonged to the League of Six Cities (Hexapolis), by which Dorian colonists in Asia Minor protected themselves against the non-Greeks of the neighbouring mainland.

The early history of these towns records brisk commercial expansion and active colonization, illustrated by the rich tombs of Camiros. Rhodian colonies extended not only eastward along the southern coast of Asia Minor, but also to the westernmost parts of the Greek world. Examples are Phaselis in Lycia, Soli in Cilicia, Salapia on the east Italian coast, Gela in Sicily, the Lipari Islands and Rhode in northeast Spain. In home waters the Rhodians dominated Karpathos and other islands.

The history of Rhodes during the Persian Wars is obscure, but later in the 5th century B.C. the three cities were enrolled in the Delian League and were democracies. In 412/411 the island revolted from Athens and became the headquarters of the Peloponnesian fleet. In 408/407 the inhabitants settled in the newly founded city of Rhodes, laid out on an exceptionally fine site according to a scientific plan, allegedly by the architect Hippodamus of Miletus. This town soon rose to considerable importance as

attracted much commerce in the Aegean and Asia Minor that had hitherto been in Athenian hands.

In the 4th century B.C. political development was arrested by constant struggles between oligarchs and democrats, who in turn brought the city under the control of Sparta (412–395, 391–378), of Athens (395–391, 378–357), and of the Carian dynasty of Mausolus (357–340). About 340 it was conquered for the Persian king by his Rhodian admiral, Mentor. In 332 it submitted to Alexander the Great, but on his death the people expelled the Macedonian garrison and henceforth not only maintained their independence but acquired great political influence.

The expansion of trade in the Hellenistic age brought especial profit to Rhodes, whose standard of coinage and code of maritime law became widely accepted in the Mediterranean. Under modified democracy, in which the six *prytaneis* formed a powerful executive, the city long enjoyed a good administration. In foreign politics it prudently avoided the ambitious schemes of Hellenistic monarchs, but gained prestige by energetic interference against all who threatened the balance of power or the security of the seas. In 305–304 it was besieged by Demetrius, who tried to bring it into alliance with his father Antigonus Monophthalmus, and earned his nickname "Poliorcetes" ("besieger") for the ingenuity of his unsuccessful siege devices. The Rhodians commemorated their successful resistance by erecting during the 290s and 280s the famous Colossus, a bronze statue of Helios (the Sun) over 100 ft. high, which probably stood near the harbour (not astride the harbour entrance). About 225 it fell down in a severe earthquake, the damages of which all Hellenistic states contributed to repair because they could not afford to see the island ruined. In the interest of trade the Rhodians undertook campaigns in the years after 220 against Byzantium, the king of Pontus, the Cretan pirates, and Philip V of Macedonia. They supported the Romans when they made war on Philip and Antiochus III of Syria on behalf of the minor Greek states and were rewarded with grants of territory in Lycia (189 B.C.). For a time the Rhodians dominated the southern Aegean but during the Third Macedonian War a false step gave Rome the excuse to deprive them of possessions in Lycia and divert their trade to Delos (167–166). However, during the two Mithradatic Wars they remained loyal to Rome and in 88 Rhodes successfully stood a siege. The Rhodian Navy did further good service for Pompey in his campaigns against the pirates and against Julius Caesar. During the triumvirate of Antony, Octavian, and Lepidus (43), the conspirator Gaius Cassius besieged and ruthlessly plundered the people for refusing to support him and, though Rhodes continued a free town for another century, its commercial prosperity was crippled, and an extensive earthquake *c.* A.D. 155 ruined it. It did, however, become the capital of the later Roman province of the islands.

In the days of its greatest power Rhodes became famous as a centre of painting and sculpture; it had a school of eclectic oratory whose chief representative was Apollonius Molon, the teacher of Cicero; it was the birthplace of the Stoic philosopher Panaetius, and the home of the poet Apollonius Rhodius and the historian Poseidonius.

The sites of Lindos, Ialysos, and Camiros, which in the most ancient times were the principal towns of the island, are clearly marked, and the first of the three is still occupied by a small town with a medieval castle, both of them dating from the time of the Knights, though the castle occupies the site of the ancient acropolis, extensively excavated by the Danes and now crudely restored. The remains of the Temple of Athena Lindia are noteworthy (rebuilt 4th century B.C.). There are few ruins of any importance on the site of either Ialysos or Camiros, but excavations at both places produced valuable and interesting results.

The history of Rhodes under the Byzantine rule is uneventful except for some temporary occupations by the Arabs (A.D. 653–658, during which the fallen Colossus was broken up and sold for scrap, and 717–718) and the gradual encroachment of Venetian traders after 1082. In the 13th century the island stood as a rule under the control of Italian adventurers, who were, however, at times compelled to acknowledge the overlordship of the emperors of Nicaea, and who failed to protect it against the depredations of Turkish corsairs.

In 1309 it was conquered by the Knights Hospitallers of St. John of Jerusalem at the instigation of the pope and the Genoese and converted into a great fortress for the protection of the southern seas against the Turks (*see* SAINT JOHN OF JERUSALEM, ORDER OF THE HOSPITAL OF). Under their mild and just rule both the native Greeks and the Italian residents were able to carry on a brisk trade. But the piratical acts of these traders, in which the Knights themselves sometimes joined, and the strategic position of the island between Constantinople and the Levant necessitated its reduction by the Ottoman sultans. A siege in 1480 by Mohammed II was repulsed with severe losses; after a second investment, during which Sultan Suleiman I is said to have lost 90,000 men out of a force of 200,000, the Knights evacuated Rhodes under an honourable capitulation (1522). The population henceforth dwindled in consequence of pestilence and emigration, and although the island recovered somewhat in the 18th century under a comparatively lenient rule, it was brought to a very low ebb as a result of the severity of its governor during the Greek revolt from the Turks.

The island was taken by the Italians from the Turks in 1912 (*see* ITALO-TURKISH WAR) and the city became capital of the administration of the Dodecanese (*q.v.*). Under the Allies' peace treaty with Italy in 1947, the island, together with the other Dodecanese islands, was awarded to Greece. The capital was under military government until 1955.

Rhodes City.—The capital, the only large town in the island, stands at its northern tip. Beside the small northern Mandrakhi port, used by small craft, lies the modern town extending westward, with the government building, the new market, national theatre, and Church of the Evangelismos (Annunciation) built in 1925 on the plan of the former Church of St. John. Beside the southern, or commercial, port rises the old walled city, its ramparts, towers, and gates being much as they were in the 15th century. The walls and defenses were built by the Knights. The

THE ISLAND OF RHODES, SHOWING ITS LOCATION IN THE AEGEAN SEA

northern area of the old city contains the Collachium, within which are the former hospital of the Knights, now a museum, and the Palace of the Grand Masters, thoroughly restored in the 20th century during the Italian period. Linking these is the Street of the Knights, in which are restored Auberges des Langues; *i.e.*, the lodges of the groups into which the Knights were divided. The 13th-century Church of the Panaghia (Virgin), and several mosques from the Turkish period, are also in the old city. About 1¼ mi. (2 km.) W of the walls is the old acropolis with excavated remains of temples of Zeus, Athena, and Apollo, and a theatre and stadium.

Rhodes is the seat of an Orthodox metropolitan and was the meeting place of Pan-Orthodox Conferences from 1961.

RHODESIA (SOUTHERN RHODESIA), an internally self-governing British colony in southern Africa which in November 1965 made a unilateral and unconstitutional declaration of independence. Rhodesia is bounded north by Zambia, northeast and east by Portuguese East Africa (Mozambique), south by the Republic of South Africa, and southwest and west by Botswana (Bechuanaland). The total area is 150,333 sq.mi. (389,363 sq.km.). The capital is Salisbury (*q.v.*).

PHYSICAL GEOGRAPHY

Geology and Structure.—Rhodesia is landlocked and has some of the world's most ancient rock formations, known collectively as the Basement Complex, and consisting of gneisses, schists, quartzites, banded ironstones, phyllites, and crystalline limestones, together with numerous other metamorphosed sedimentary and igneous rocks, which are associated with granites and gneisses of a somewhat later period. These Basement rocks occupy large areas of Rhodesia, the schist belts containing veins and lodes of minerals including gold, silver, and many others. Overlying the Basement Complex is a system of Precambrian conglomerates, sandstones, and dolomite of which the Lomagundi System is an example. In the later Precambrian basic intrusions resulted in the formation of the great dike, the norite of the dike now forming an almost straight outcrop trending a little west of south for about 320 mi. (515 km.). Chrome ore, nickel, and platinum are associated with the lower eruptive rocks. In the latest Precambrian the deposition of shales and limestones in the western part of the country formed the Umkondo System, remnants of which are found to the south of the middle Zambezi and in the eastern highlands. The tillite, sandstones, shales, and subsequently the lavas of the Karroo System were formed from the Carboniferous to the early Jurassic. The system extends from Tuli on the southern border northeastward into the Sabi Valley and occupies the floor of the Zambezi Valley, from which it spreads southward through Sebungwe District into the highlands around Bulawayo and Gwelo. Among later formations are the Cretaceous conglomerates and limestones, found in the Zambezi trough and the Limpopo-Sabi depression, and the Kalahari System, composed of limestone, sandstone, and loose sand, which is believed to date from the early Tertiary. Redistributed Kalahari sand and alluvium are deposits which have accumulated since Quaternary and Recent times.

MAJOR TOWNS AND TRANSPORTATION ROUTES OF RHODESIA

Relief and Drainage.—The surface features of Rhodesia have been considerably affected by large-scale faulting. During the early Cretaceous a southwest-northeast trending fault formed the middle Zambezi trough and, in the extreme south, the Limpopo-Sabi depression was also affected by major west-east and north-south faulting. These rifting movements have broken up the plateau surface represented by the highlands. These consist of a fairly even surface, more than 4,000 ft. (1,200 m.) in altitude, in which the Plumtree-Marandellas watershed divides the middle Zambezi from the middle Limpopo drainage. A lower area of midland surface (2,000–4,000 ft.) is transitional between the highland and the lowland (below 2,000 ft.). The main mountain features in these altitudinal zones are formed by hard outcrops of the granite-gneiss, such as the Matopo Hills and the innumerable rounded *kopjes* ("hillocks") composed of ball granite or by the schist belts with their prominent ridges of quartzite and banded ironstone. The great dike (see *Geology and Structure* above) forms a series of long, low ridges increasing in height to the north to about 1,500 ft. (450 m.) above the plateau surface in the Umvukwe Range. To the southeast of the middle Zambezi Valley the most prominent features are faulted blocks such as the Siwalis and the Matusadona plateaus trending southwest-northeast. The highest part of the country, however, is the eastern highland area, along the eastern boundary, where the Melsetter Highlands, to the south of Umtali, rise in the peak Himalaya to 7,253 ft. (2,211 m.), and, to the north of Umtali, the Inyanga Plateau attains its greatest altitude in the peak Inyangana (8,503 ft. [2,592 m.]).

Physiographic Regions.—The structure and surface of Rhodesia have given rise to five defined physiographic regions, of which the first—highlands of more than 4,000 ft. in altitude—is represented by the eastern highlands. The second region, the Sebungwe midland, comprises land lying between 2,000 and 4,000 ft., which forms a transitional surface between the highland to the southeast and the middle Zambezi trough, and also the upper Mazoe basin. The third type is rift valley which in Rhodesia is the middle Zambezi or Gwembe trough. The fourth region is the Kalahari sand surface, represented by the extremely flat Wankie-Nyamandhlovu sand plain in the southwestern part of the country. The fifth region is the drainage basin comprising the northern part of the Limpopo-Sabi depression which originated in extensive west-east and north-south faulting and has since been extended northward and northwestward by vigorous headstream erosion.

Climate.—It is generally agreed that there are three seasons in Rhodesia. The first season comprises the cool, dry winter months of May, June, and July; the second, the hot, dry months of August, September, and October; and the third, the warm months of summer rain during November–April. On the whole the considerable altitude partly compensates for the low latitude, temperatures being closely related to altitude. Thus Beitbridge

(1,505 ft. [459 m.]), on the Limpopo River, has a coolest month (June) mean temperature of 60° F (15° C) and a warmest month (November) mean temperature of 80° F (27° C). To the north of the Limpopo Valley the coolest month is generally July and the warmest October. For the following stations, therefore, the July and October means are given. On the whole plateau stations have lower temperatures than valley stations: thus Bulawayo (56° and 72° F) at 4,405 ft. and Salisbury (56° and 70° F) at 4,831 ft. are considerably cooler than Beitbridge; and Inyanga (52° and 60° F) in the eastern highlands, at 5,514 ft., has still lower temperatures. Farther north, in the Zambezi trough, Chirundu, at 1,312 ft. (400 m.), has a July mean of 68° F and an October mean of 87° F, with a mean maximum for October of 100° F.

Annual rainfall is greatest on parts of the eastern highlands, where it exceeds 70 in. (1,800 mm.). Westward there is a marked decrease in the middle Zambezi trough to between 25 and 30 in. (635 and 760 mm.). The areas receiving least rainfall are in the far south where, in the Limpopo Valley, annual falls of less than 25 in. are usual.

Vegetation.—The country's climate, with its wet summers and dry winters, has produced a vegetation in which savanna, either as dense or widely dispersed tree growth, is predominant, with some grassland and swamp, and Kalahari sand in the extreme west. Between 3,500 and 5,000 ft. various species of *Brachystegia* and *Isoberlinia* are the dominant savanna. Other types include the mangwe (*Terminalia sericea*); the thorn savanna; the umgusu (*Baikiaea plurijuga*); and, in the dry, hot valleys of the Limpopo and the Zambezi rivers, the mopane woodland, with which the baobab, the knobthorn (*Acacia nigrescens*), and a species of doum palm are found in association. True forest grows in the areas of heavy rainfall on the eastern highlands. There are also found the yellowwood and cedar; and at lower levels red and brown Rhodesian mahoganies (*Khaya nyasica* and *Lovoa swynnertonia*) are common. Pure grassland occurs in the eastern highlands bordering the forests. (*See* also *Forestry* below.)

Animal Life.—Primates of Rhodesia include the vervet, the Samango monkey, the smaller and larger galagos (bush babies), and the chacma, Rhodesian, and yellow baboons. Among the carnivora are the lion, leopard, cheetah, spotted and brown hyena, aardvark, serval, civet, genet, mongoose, zorilla (striped polecat), ratel (honey badger), black-backed and side-striped jackals, hunting dog, bat-eared fox, ant bear, and scaly anteater. The elephant is found in the northwestern, northern, and northeastern parts of the country. The hippopotamus is to be seen in the larger rivers and the giraffe in the extreme west and in the southwest. Members of the Bovidae family include the eland, greater kudu, blue duiker, common and singsong waterbuck, reedbuck, impala, klipspringer, oribi, steinbok, Sharpe's grysbok, sable and roan antelopes, hartebeest, and tsessebe. Reptiles and birds abound and there is a wide variety of insects.

National Parks and Reserves.—The Wankie National Park, in northwestern Rhodesia, extends from the Bulawayo-Victoria Falls railway line to the boundary of Botswana, covering an area of more than 5,000 sq.mi. (13,000 sq.km.). It includes the Robins Game Reserve and the adjacent Khazuma Pan Reserve. Most of the animal life of Rhodesia, Zambia, and Malawi is found in this park. Other areas where game can be seen are the Robert McIlwaine National Park, near Salisbury; the Matopos National Park and the Khami ruins, both near Bulawayo; and the Zimbabwe National Park. (J. H. Wn.; X.)

HISTORY

The remains of Stone Age cultures dating back 500,000 years have been found in Rhodesia, and it is thought that the Bushmen, who still survive mostly in the Kalahari Desert of Botswana, are the last descendants of these original inhabitants of southern and central Africa. They were driven into the desert by the Bantu tribes during the long migrations from the north in the course of which the Bantu populated much of Africa from Lake Chad to Zululand. The first Bantu are thought to have reached Rhodesia between the 5th and 10th centuries A.D. The stone ruins of Zimbabwe (*q.v.*) date mainly from about the 9th century, but it is unlikely that these are of Bantu origin.

Portuguese Exploration.—When the Portuguese arrived on the east coast of Africa between 1500 and 1520, they found that the civilization which had produced these ruins had already vanished. From their earliest days on the coast the Portuguese dreamed of opening up the interior and establishing an intercoastal route to connect their eastern settlements with Angola in the west. The first European to enter Rhodesia was probably António Fernandes, who tried to cross the continent and reached the neighbourhood of Que Que. Nearly 50 years afterward the "emperor" Monomotapa (*q.v.*) was baptized by a Jesuit father, and in 1569 an abortive military expedition entered the interior in search of gold. (*See* further Portuguese East Africa: *History.*)

Bantu Migration: the Arrival of Missionaries.—A second great movement of the Bantu peoples began in 1830, this time from the south. To escape from the power of the great Zulu chief Chaka (Shaka) three important tribes fled northward, one of them the Ndebele (*q.v.;* Matabele), who carved out a kingdom for themselves in Rhodesia. The Ndebele were warriors and pastoralists, in the Zulu tradition, and under their formidable chief Moselekatse (Mzilikazi) they mastered and dispossessed the weaker tribes, known collectively as Shona (Mashona), who were sedentary, peaceful tillers of the land. For more than half a century, until the coming of European rule, the Ndebele continued to enslave and plunder the Shona. During this period, however, British and Afrikaner hunters, traders, and prospectors had begun to move up from the south, and with them came the missionaries. Robert Moffat, father-in-law of David Livingstone, visited Moselekatse in 1857, and this meeting led to the establishment in 1861 of the first mission to the Ndebele by the London Missionary Society.

The British South Africa Company.—In South Africa, Cecil Rhodes (*q.v.*) was considering the extension of British power northward into the heart of the continent. In 1887 the Portuguese laid claim to the whole interior between Mozambique and Angola in a final attempt to secure their intercoastal route, and this spurred Rhodes into immediate action. He arranged for the dispatch of J. S. Moffat to Matabeleland to safeguard British

interests, and in February 1888 Lobengula, the son and successor of Moselekatse, signed a treaty by which he promised not to cede any territory without the consent of the British high commissioner in Cape Colony. Rhodes next sent C. D. Rudd, J. R. Maguire, and F. R. Thompson to Lobengula, and in October 1888 the chief granted them a mineral concession covering the whole of the country south of the Zambezi. Rhodes then went to London and persuaded the British prime minister, Lord Salisbury, to obtain the grant of a royal charter entrusting him and his associates with the occupation, administration, and development of central Africa.

The British South Africa Company (*q.v.*) was formed and received its charter in October 1889. Its objects were: (1) to extend the railway from Kimberley northward to the Zambezi; (2) to encourage emigration and colonization; (3) to promote trade and commerce; and (4) to secure all mineral rights, in return for guarantees of protection and security of rights to the tribal chiefs.

Nine months later a pioneer column, led by Lieut. Col. E. G. Pennefather, guided by the famous hunter F. C. Selous, and consisting of about 200 settlers and 500 police, set out from Bechuanaland. The pioneers skirted Matabeleland and reached the site of the future capital of Rhodesia without incident on Sept. 12, 1890. They called it Fort Salisbury after the British prime minister. Following a border skirmish in 1891 an Anglo-Portuguese agreement was signed (subsequently confirmed by an international award in 1897) which finally settled the frontier with Mozambique and ended the Portuguese dream of an intercoastal route.

The Ndebele soon discovered that they were no longer allowed to raid and pillage the Shona with impunity and, resenting this interference, in 1893 they took up arms, being defeated only after months of strenuous fighting. Lobengula fled and the company assumed administrative control of Matabeleland. In 1895 many of the pioneers were persuaded to take part in the Jameson raid into the Transvaal and were captured and sent to England for trial (*see* TRANSVAAL: *History: Jameson Raid*). In the same year the territories administered by the company, which had previously been loosely known as Zambesia, were formally named Rhodesia, by proclamation. In 1896 the Ndebele rose again, 10,000 of them forcing the settlers at Bulawayo, a newly established township in Matabeleland, to take up a defensive position. Returning from London, Rhodes went out, unarmed, to meet the chiefs of the Ndebele and persuaded them to make peace. The Shona had at first accepted the Europeans, but they too became rebellious and the whole country was not pacified until 1897.

Economic and Political Development.—By 1892 about 1,500 settlers from the south had arrived in Rhodesia. The railway reached Bulawayo in 1896 and the Victoria Falls in 1904. By the following year there were 12,500 settlers in the country and in 1909 gold exports were worth more than £2,500,000. Agricultural development, however, was slower, and it was not until 1907 that steps were taken to facilitate the acquisition of land. By 1911 tobacco to the annual value of nearly £35,000 was being exported and the European population had risen to 23,600.

From the earliest years the settlers had demanded representation on the Legislative Council, which in 1903 comprised seven company officials and seven elected representatives of the settlers. In 1907 the settlers were given a majority of seats. In 1914, when the 25-year term of the company's charter was due to expire, the settlers, faced with the alternative of joining the Union of South Africa, asked for the continuation of the charter pending the grant of self-government. The British government therefore extended the charter for a further ten years, with the proviso, however, that self-government could be granted earlier if the settlers showed themselves capable of administering the country unaided. During World War I many Rhodesians, both Europeans and Africans, joined the armed services and during that period little attention was paid to constitutional development, though there were still disputes between the settler-dominated Legislative Council and the company, particularly about the ownership of unalienated land.

Self-Government.—As soon as the war ended the pressure for self-government was resumed and a royal commission under Lord Buxton was appointed to consider the future of the territory. As a result of the commission's report a referendum of the electors among the 34,000 Europeans in the country was held in 1922, on the choice between entry into the Union of South Africa as its fifth province and full internal self-government. In spite of the offer of generous terms by the Union prime minister, Gen. J. C. Smuts, 8,774 people voted for self-government as against 5,989 for joining the Union. On Sept. 12, 1923, the 33rd anniversary of the arrival of the pioneers at Fort Salisbury, Southern Rhodesia was annexed to the crown and became a self-governing colony. The British government retained control of external affairs and a final veto in respect of legislation directly affecting Africans.

The interwar period was one of general progress, with the development of a reasonably prosperous economy based on copper, gold, and other minerals, maize (corn), tobacco, and cattle. During World War II Rhodesian units served with distinction and in the colony itself an important air-training centre for Royal Air Force pilots was established. By 1953 Southern Rhodesia had a European population of 157,000 and an annual revenue of more than £28,000,000.

The declared policy of Sir Godfrey Huggins (later Lord Malvern), who was prime minister of Southern Rhodesia for 20 years, was to build a society in accord with Cecil Rhodes's dictum of "equal rights for all civilized men," in which merit and not colour should be the test of political and economic advancement. He believed that political power should not be given to the Africans until they were sufficiently experienced to know how to exercise it in friendly cooperation with the Europeans and thus to maintain the economic development built up over the years.

A second principle in which Lord Malvern and most other Europeans in Southern Rhodesia and Northern Rhodesia (later Zambia) profoundly believed was that the two countries should be joined together, both for their mutual economic benefit and to ensure the establishment of a powerful multiracial state based on British culture and traditions and on liberal principles. Malvern failed to

BY COURTESY OF RHODESIA HOUSE, LONDON

SALISBURY, CAPITAL OF RHODESIA

secure their amalgamation, but he supported the federation of Southern Rhodesia, Northern Rhodesia, and Nyasaland (later Malawi) when that solution was accepted by the British government in 1953. (*See* RHODESIA AND NYASALAND, FEDERATION OF.)

Federation Period.—Constitutional development continued in Southern Rhodesia after federation. In 1957 a new electoral law was passed providing for a common roll of voters with a special roll for those with lower qualifications. At the same time there was growing political consciousness among the African population, together with increasing hostility to the idea of federation. In 1960 disturbances broke out after the arrest of some African nationalist leaders belonging to the National Democratic Party (NDP). In the following year proposals for a new constitution—approved by the electorate in a referendum—were strongly criticized by the NDP, which considered them insufficient to meet African demands. The NDP was subsequently banned for acts of intimidation. After that, the African nationalist movement split into two rival organizations, the Zimbabwe African People's Union (ZAPU), led by Joshua Nkomo, and the Zimbabwe African National Union (ZANU), led by Ndabaningi Sithole. The situation in Southern Rhodesia began to attract the attention of the United Nations Special Committee on Colonialism, and in June 1962 the UN General Assembly passed a resolution calling for a more liberal constitution for the territory.

The election of December 1962, when the new constitution (see *Administration and Social Conditions,* below) came into force, was boycotted by the African nationalists. It resulted in the defeat of the ruling United Federal Party by the more conservative Rhodesian Front. Winston Field became prime minister. At the end of 1963 the federation was dissolved, and Southern Rhodesia reverted to its former status as a colony.

Unilateral Declaration of Independence.—The U.K. government was now faced with, on the one hand, demands by the new Rhodesian government for complete independence and, on the other, by pressure from the UN and much of the rest of the Commonwealth for a change in the constitution to suit the Africans, who wanted first majority rule and then independence. In a referendum held in November 1964 the Rhodesian Front government led by Ian Smith (prime minister from April 1964) gained the approval of the electorate for independence under the existing constitution. It further strengthened its position by an overwhelming victory in the general election of 1965.

During 1965 the possibility that the Rhodesian government would declare its independence unilaterally grew steadily stronger. While accepting the need for independence, the British government wanted an assurance that the basis upon which this would be granted would be acceptable to the people of the country as a whole. In October fruitless discussions on this issue were held between the British and Rhodesian prime ministers in London and in Salisbury.

On Nov. 11 the Rhodesian government under the leadership of Smith proclaimed the country's independence. The British government immediately declared this move to be an act of rebellion and began (with the general support of the UN) the imposition of economic sanctions.

The freezing of Rhodesian sterling balances in London, the progressive curtailment of imports from Rhodesia by other countries, and the imposition of an oil embargo in December 1965, and the cutting off of trade between Rhodesia and Britain (its best customer) in January 1966, began slowly but cumulatively to have an effect on the Rhodesian economy. Rhodesia's trade with the Republic of South Africa, however, was not affected, and landlocked Zambia had to continue to buy consumer goods from Rhodesia.

At two Commonwealth prime ministers' conferences held in Lagos and London during 1966, increasing pressure was put upon the British government to take more drastic steps to end the rebellion in Rhodesia. In September the British government undertook that, if the illegal government had not accepted its terms for a settlement by the end of the year it would, if supported by the rest of the Commonwealth, propose to the UN the imposition of mandatory sanctions on selected commodities considered to be vital to the Rhodesian economy.

In Rhodesia itself most of the African nationalist leaders were in detention and outbreaks of violence were few. Disaffection within the University College in Salisbury resulted in arrests of students and lecturers and the deportation of eight lecturers. Security precautions were taken under regulations consolidated in March in the Emergency Powers Amendment Act, and there was censorship of news. Import control, direction of labour, and gasoline rationing were introduced to safeguard the economy.

A meeting held in the British cruiser "Tiger" off Gibraltar during Dec. 2–4, 1966, between representatives of Britain and Rhodesia led by Harold Wilson and Ian Smith, failed to produce any immediate solution of the crisis. Britain thereupon applied to the UN Security Council for the imposition of selective mandatory sanctions against Rhodesia. These, after amendment by the African members of the council to include an embargo on imports of oil, were agreed on Dec. 16. (K. G. B.)

POPULATION

In 1962 the total population of Rhodesia was 3,857,470, of whom 3,618,150 were Africans. The census of 1962 was the first complete census of Africans ever taken in Rhodesia. In 1956 the African population had been estimated at 2,540,000 and in 1946 at 1,770,000. The September 1961 census of non-Africans showed these to number 239,316, comprising 221,504 Europeans, 7,253 Asians, and 10,559 other non-Africans. At the 1956 census the European population was 177,124 and in 1946 it was 82,386; it had thus more than doubled in ten years. Immigration was the major factor in this increase. According to the 1956 census less than one-third of the European population had been born in the country, and the majority of migrants (of predominantly British stock) had come from South Africa and the United Kingdom. Populations of chief towns (1961–62) are: Salisbury (*q.v.;* 157,795); Bulawayo (*q.v.;* 176,646); and Umtali, 38,451. Other towns are Gwelo, Que Que, and Gatooma.

The indigenous people of Rhodesia are the Bushmen, of whom there remain only a handful, and the Bantu. The Bushmen, who live along the western border of Matabeleland, are now of mixed race, having intermarried with the Bantu. The Bantu of Rhodesia, who belong to the southern section of the Bantu peoples, are generally divided into two groups, each containing a large number of smaller, tribal divisions: the Ndebele, the smaller group, occupy roughly the southeastern area of the country; and the Shona-speaking peoples the rest of the country. They are pastoral peoples who also cultivate corn (maize) and finger millet. They follow patrilineal descent and practise virilocal marriage. Before the establishment of British control some tribes, notably the Ndebele, were highly centralized chiefdoms headed by powerful chiefs. Most tribes, however, were organized into small autonomous units led by chiefs with limited secular and spiritual power. Ancestor worship is the basis of traditional religion. Among the Shona-speaking peoples there are spirit mediums through whom the spirits of powerful ancestors are believed to speak. A considerable number profess Christianity. Although the African population is still predominantly rural, Africans have settled in towns in increasing numbers and are adopting European modes of behaviour.

The majority of Africans speak Bantu languages, Ndebele and Shona being the main languages. English is the language of the administration and of most Europeans, though some immigrants from South Africa are Afrikaans-speaking. (J. C. MI.; X.)

ADMINISTRATION AND SOCIAL CONDITIONS

Constitution and Government.—Under the 1961 constitution the British sovereign is represented in Rhodesia by a governor. The Parliament comprises a Governor's Council and a single-chamber Legislative Assembly of 65 members. The Governor's Council (cabinet) consisting of the prime minister and other ministers is responsible to the Legislative Assembly, which is presided over by a speaker. The franchise is extended to voters of all races aged 21 or more registered on one of two electoral rolls, subject to certain property, income, or educational qualifications

which effectively limit African participation. Fifty members of the Legislative Assembly, representing electoral districts, are elected by the more highly qualified voters of the "A" roll; the remaining 15, representing electoral districts, are elected by the voters of the "B" roll, who have lower qualifications. The constitution also eliminates the reserved powers previously vested in the British government for the disallowance of laws passed by the Legislative Assembly, with the exception of matters affecting the position of the sovereign and the governor; international obligations; and undertakings given by the Rhodesian government in respect of loans under the Colonial Stock acts. Notable features of this constitution are the declaration of rights and the provision for a Constitutional Council. The declaration of rights concerns the fundamental rights and freedoms of the people of Rhodesia irrespective of race, colour, or creed, and provides for the enforcement of these rights and freedoms in the courts, with ultimately the right of appeal to the Privy Council. The main function of the Constitutional Council is to scrutinize all bills passed by the Legislative Assembly to ensure that their provisions conform to the declaration of rights.

Following Rhodesia's unilateral declaration of independence a new constitution was announced on Nov. 11, 1965, and approved by the Rhodesian Parliament on Feb. 18, 1966. It contained several important new provisions: it set aside the office of governor and made arrangements for the appointment of an "officer administering the government"; it removed the power of the British Parliament to legislate for Rhodesia; it repudiated the power of the British crown to issue orders in council under U.K. legislation in respect of Rhodesia; and it abolished appeals to the Privy Council. Certain provisions—including franchise qualifications, the Constitutional Council, the declaration of rights, and matters concerning tribal trust lands—which were previously subject to approval by the four principal races voting in separate referendums, or by the British government, could henceforth be amended by a two-thirds majority of the total membership of Parliament.

In the smaller European communities local government is the responsibility of local boards or committees; in the larger communities it is carried on by management boards or by municipal councils. These are elected bodies with certain powers, including the right to levy rates, to maintain and build roads, and to provide services such as water, electricity, and transport. They are also responsible for the administration of African townships built near European residential and commercial areas.

Living Conditions.—*Employment.*—In the 1960s more than 830,000 Africans and more than 90,000 non-Africans were employed in Rhodesia. Africans were mostly employed in agriculture, forestry and fishing, and services, including domestic service. About 26,000 non-Africans were employed in services and about 24,700 in commerce. Almost 50% of the African labour force was composed of immigrants from Malawi, Zambia, and Mozambique. From 1961, however, steps were taken to restrict the employment of immigrant labour. The conditions of service of all workers except those engaged in agriculture and private domestic service are regulated by the Industrial Conciliation Act, 1959.

Housing.—Housing for Europeans and Asians is mainly the responsibility of private enterprise. Local authorities generally provide housing for the Africans and Coloureds (people of mixed ancestry). When, in the early 1950s, the accommodation of African urban workers became a serious problem, the government began a program to house married African urban workers, in addition to housing projects carried out by local authorities.

Health and Social Welfare.—Rhodesia had six central hospitals, eight general hospitals, and a number of district and rural hospitals in the 1960s. In addition, there were several special institutions, including mental and tuberculosis hospitals.

Welfare services include the supervision of juvenile delinquents, the rehabilitation of maladjusted adults, including alcoholics, the care of the aged and physically handicapped, and the encouragement of voluntary social services. Private institutions for children and old people are supported by the government.

Education.—By the later 1960s about 95% of African children of school age were receiving a minimum of five years' education. Most schools were run by missions which were grant-aided by the government. More than 650,000 African children were attending primary and about 14,000 secondary schools. Approximately 37,000 European children were in government primary and 20,000 in government secondary schools. There were also about 4,000 European children at private primary and 3,000 at private secondary schools. Students of all races attended the University College at Salisbury.

Justice.—The Ministry of Law and Order, formed in September 1962, is responsible for the maintenance of law and order and for the prosecution of criminals in the courts. The High Court, established in 1898, has criminal and civil jurisdiction over all persons. Most criminal and civil litigation is conducted in magistrates' courts. There are also African courts with jurisdiction in matters which can be decided by native law and custom.

The Rhodesian police force—composed of both Africans and non-Africans—is also controlled by the Ministry of Law and Order.

Defense.—The Rhodesian Army consists of about 3,400 regulars and 8,400 territorials and reservists. The Air Force has a strength of about 1,000 men and nearly 100 aircraft.

THE ECONOMY

Sanctions imposed against Rhodesia after the unilateral declaration of independence, had a severe effect on the country's economy, the prohibition by many countries of the import of Rhodesian tobacco being believed to have been particularly damaging. It is not, however, possible to form any accurate estimate of the effect of sanctions (publication of statistics being withheld) in the period immediately after the declaration of independence; the following assessment therefore refers to the condition of the economy as it was before November 1965.

The Rhodesian economy is based primarily on agriculture, with tobacco as the main export product, but mining and an increasing number of secondary industries are assuming major importance. These are backed by the subsistence agriculture practised by the great majority of the African population. In agriculture, mining, and industry Africans are generally employed as unskilled and semiskilled labour.

Production.—*Agriculture.*—Because of the importance of agriculture every effort is made to improve farming methods wherever possible, special attention being paid to irrigation and to better land utilization in general. Rhodesia's sandy soil has proved especially suitable for the production of Virginia flue-cured tobacco, the output of which in the mid-1960s was about 300,000,000 lb. annually. This represented an increase in production and value of more than 100% compared with the 1950s. The increase has

BY COURTESY OF RHODESIA HOUSE, LONDON

FARMER WATERING TOBACCO SEEDLINGS. TOBACCO IS A MAJOR CASH CROP IN RHODESIA

been chiefly due to higher yields per acre. Most crops, including tobacco, corn (maize), peanuts, and cotton, are grown in the summer. Corn is the most important grain. In many parts it is a staple of subsistence agriculture, is used in livestock feed, and has become increasingly significant as an export crop. Wheat, grown under irrigation, is the most important winter crop, and attempts are being made to evolve better strains. Other winter crops include barley, oats, peas, rye, and cabbage. Sugar production (beet) was mounting rapidly in the 1960s.

Under the stimulus of cooperative programs African farmers are engaged in the production of the country's chief crops. In the 1960s Africans harvested annually about 3,300,000 bags (200 lb. each) of corn (about one-third of the total production), while the production of wheat (about 15,000 bags) was much higher than the European output. Other crops grown by Africans include Turkish tobacco (which requires little capital investment and gives a high yield), tea, sugar, Arabian coffee, vegetables, and fruit.

Livestock.—In the mid-1960s the cattle population amounted to about 3,500,000, of which more than half were owned by Africans. The value of the output of the livestock industry, which developed under a stimulus of a guaranteed market with guaranteed minimum prices, was second only to tobacco.

Forestry.—Before independence was declared the control of crown forests and the establishment and maintenance of plantations was the responsibility of the Southern Rhodesian Forestry Commission, founded in 1954. Utilized forests, covering an area of about 2,000,000 ac. (800,000 ha.), yield mainly Rhodesian teak, which is used for railway ties (sleepers) and parquet flooring. The main species of trees being planted as part of afforestation projects were eucalyptus, pines, and wattle. By the 1960s the total area planted to eucalyptus exceeded 60,000 ac. (24,000 ha.) and the total area planted to pine was about 100,000 ac. (40,000 ha.).

Mining.—Rhodesia's mining industry has steadily expanded, and the industry forms an important sector of the economy. More than 30 minerals are produced, the total annual output being valued at about £28,000,000 ($78,500,000) in the mid-1960s. The most important were asbestos and gold, followed by chrome, copper, and coal. The value of production of these minerals (except gold) almost doubled between the 1950s and 1960s. World resources of asbestos are limited, and substantial capital investment has been made in efforts to obtain access to additional Rhodesian reserves of asbestos ore. Chrome of all grades is found in abundance in Rhodesia, which is the world's second biggest producer. The chief coal deposits are at Wankie, which has reserves of more than 500,000,000 tons. Production of tin is also assuming increasing importance. There are also substantial reserves of high-grade iron ore.

Industries.—In value, the country's manufacturing industry makes the greatest contribution to the gross domestic product (or at least did so before the declaration of independence). Its gross output rose from about £90,000,000 in the early 1950s to nearly £200,000,000 in the mid-1960s. The chief industries are iron and steel, metal products, textiles, clothing and footwear, chemicals, timber, and food processing. Most large towns contain manufacturing industries, particularly Salisbury and Bulawayo. The iron and steel industry is situated in the vicinity of Que Que (near the iron ore and limestone deposits), and heavy industries based on iron and steel are established in the town. At Umtali there are pulp, board, and wattle extract industries, drawing their raw material from the forests of exotic timber and wattle in the eastern districts of the country. Gatooma has a cotton-ginning plant, which can handle nearly 50,000,000 lb. of seed cotton in a season, and spinning mills. Bulawayo has railway workshops, a radio manufacturing industry, and a tire factory; a ferrochrome industry is found in Gwelo. The country also possesses cement factories and motor vehicle assembly plants.

Power.—Most of Rhodesia's generating requirements are met by the Kariba hydroelectric project (*see* KARIBA, LAKE). Consumption of electricity has risen rapidly and production increased from about 740,000,000 kw. in the early 1950s to more than 2,000,000,000 kw. in the mid-1960s.

An oil pipeline runs from Beira, in (Portuguese) Mozambique, to Rhodesia's only oil refinery, near Umtali.

Trade and Finance.—In the 1960s the chief Rhodesian exports were tobacco, asbestos, corn, meat and meat products, pig iron, and chrome ore. Among the chief imports were wheat, petroleum, fertilizers, cotton fabrics, and motor vehicles.

The principal sources of revenue were taxes on income and profits, customs duties, personal tax, and interest on loans, deposits, etc. Annual revenue totaled about £75,000,000 ($210,200,000). The principal items of expenditure were service of loans, African education, police, and internal affairs. Expenditure was about £70,000,000 annually. The Reserve Bank of Rhodesia issues Rhodesia's currency. It is also empowered to control banking, deal in gold and currencies, and exercise exchange control functions.

Transport and Communications.—The Rhodesian government is responsible for about 5,200 mi. (8,400 km.) of road of which about 3,000 mi. (4,800 km.) are bituminized. There are in addition nearly 14,000 mi. under the supervision of the road councils in the European areas and about 29,000 mi. in the African areas. Both Rhodesia and Zambia are served by Rhodesia Railways (owned jointly by both countries) which are linked with South African Railways. There are nearly 1,600 mi. (2,600 km.) of single-track railway in Rhodesia, of 3 ft. 6 in. gauge. There is an international airport at Salisbury, and Bulawayo, Fort Victoria, and Kariba also have airports. The chief towns are linked by Central African Airways, and other services are operated by British United Airways and Commercial Air Services.

Communications include direct radio, cable, and telephone services to the United Kingdom, and the country has a telephone network. There are broadcasting stations at Salisbury, Bulawayo, and Gwelo.

RHODESIA, NORTHERN: *see* ZAMBIA.

RHODESIA AND NYASALAND, FEDERATION OF, a short-lived federation of three British central African countries, Northern Rhodesia, Southern Rhodesia and Nyasaland, which came into existence in Sept. 1953 and was dissolved at the end of 1963. This article deals with the events leading up to the formation of the federation and the history of the federation itself. For all other information concerning the countries which composed the federation *see* MALAWI (the former Nyasaland; *q.v.*); RHODESIA; and ZAMBIA (the former Northern Rhodesia).

Europeans in the Rhodesias began to press for the amalgamation of the two territories during the 1930s, and after World War II Roy (later Sir Roy) Welensky in Northern Rhodesia and Sir Godfrey Huggins (Lord Malvern) in Southern Rhodesia abandoned their campaign for this union (including, by then, Nyasaland) only when the British government made it clear that it was not prepared entirely to relinquish its responsibilities for Northern Rhodesia and Nyasaland. It did, however, agree that there were forceful economic and political arguments for creating a strong state based on co-operation between Europeans and Africans. The solution was a federation of the three territories in which those matters which most directly affected the lives of the Africans, such as the administration of land, African taxation and local government, African primary and secondary education, and agriculture, were to be left with the territorial governments. The commonwealth relations office would be in charge of federal and

Southern Rhodesian affairs but the colonial office would retain full responsibility for the political advancement of peoples in the protectorates, with the aim of granting them self-government.

All these safeguards, however, did not satisfy the Africans in Northern Rhodesia and Nyasaland who still feared that eventually their destinies would be controlled by the 220,000 Europeans in Southern Rhodesia, whereas, if they stayed out of the federation, they would achieve complete national independence. There was much controversy in Britain over this issue, but the Conservative government held to the view that the proposed federation would so greatly benefit all the peoples in each territory that the Africans would in time lose their fears and give it their support. Accordingly, after the Europeans in Southern Rhodesia had, in a referendum, voted in favour of federation by a large majority, the Federation of Rhodesia and Nyasaland was formally established on Sept. 3, 1953. Lord Llewellin was appointed first governor general of the federation and its first prime minister was Lord Malvern, who, on his retirement in 1956, was succeeded by Sir Roy Welensky. The federal assembly consisted of a speaker and an elected majority. The federal government's responsibilities included external affairs, defense, immigration, external trade and fiscal matters. A special feature of the constitution was the African Affairs Board, designed to safeguard African interests.

The belief that the creation of the federation would result in great economic progress was fully justified, one remarkable achievement being the completion of the Kariba dam on the Zambezi in 1960 at the cost of about £120,000,000. There was also a marked liberalization of social policies in the Rhodesias, especially in Southern Rhodesia, where the tradition of a "white man's country" and economic competition between Europeans and Africans made this particularly difficult.

Nevertheless, with the achievement of independence by other African countries, nationalist feeling was rapidly increasing, and the opposition of Africans to the idea of federation led to the growth of nationalist political parties in all three territories and to considerable unrest.

In 1960 a comprehensive inquiry into the federal constitution was instituted by a commission under the chairmanship of Lord Monckton. Its conclusions were that African opposition to the federation had grown to the point where the latter could not survive unless it were so modified as to be made acceptable to the peoples of all the constituent territories, and that each territory should be given the right to secede. The provision about secession was strongly opposed by Sir Roy Welensky and a subsequent conference in London on the future of the federation proved abortive. It was, therefore, decided to postpone the conference until the next steps in constitutional reform in Northern Rhodesia and Nyasaland had been taken. In 1961 Nyasaland was given representative government. In April 1962 the United Federal party, under Sir Roy Welensky, was returned to power with a greatly increased majority in the federal general election, which had been boycotted by most of the other parties.

In March 1962 the British government took away from the colonial office and the commonwealth relations office all responsibility for the territories in the federation, which were thenceforth entrusted to a newly formed Central Africa office.

Toward the end of 1962 an African-dominated government took office in Northern Rhodesia and elections subsequently held in Southern Rhodesia, which were boycotted by the African parties, resulted in the defeat of the ruling United Federal party by the more conservative Rhodesian Front. In Dec. 1962 the U.K. government announced its acceptance in principle of Nyasaland's right to secede from the federation, following this in March 1963 with a declaration of any territory's right to secede. The governments of all three territories were then demanding independence and after a conference at Victoria falls in June–July, attended by representatives of the U.K., federal, Northern Rhodesian and Southern Rhodesian governments, the U.K. passed an enabling measure to start the process of dissolution of the federation. The federation officially came to an end on Dec. 31, 1963.

RHODES SCHOLARSHIPS: *see* RHODES, CECIL JOHN; STUDENT AID.

RHODIUM is a chemical element which is a precious silver-white metal. It is one of the platinum metals (*q.v.*). The symbol for rhodium is Rh. Its atomic number is 45; its atomic weight, 102.905. It has a specific gravity of 12.4 and melts at 1,966° C; thus it is difficult to fuse or cast. It is fairly hard and cannot be easily worked at room temperature; but it can be forged above 800° C, a red heat.

The surface of the metal has a high reflectivity for light and is not corroded or tarnished by the atmosphere at room temperature. It is frequently electroplated onto metal objects and polished to give permanent attractive surfaces for jewelry and other decorative purposes. In particular, the black tarnish of silver is avoided by the use of rhodium plate. Rhodium also serves for the preparation of "silvered" surfaces for reflectors of searchlights and motion-picture projectors.

Rhodium added to platinum in small amounts yields alloys which are harder and lose weight at high temperatures even more slowly than does pure platinum. Therefore crucibles for heating materials in the chemical laboratory are commonly made from these alloys. In the industrial manufacture of nitric acid, gauze catalysts of the rhodium-platinum alloys are used because of their ability to withstand the flame temperature as ammonia is burned to nitric oxide.

A wire of the alloy 10% rhodium–90% platinum joined to a wire of pure platinum forms an excellent thermocouple for measuring high temperatures in an oxidizing atmosphere. The international temperature scale is defined over the region from 660° to 1,063° C by the electromotive force of this thermocouple.

The only stable isotope for rhodium has a mass number of 103, *i.e.*, Rh^{103}. Its nuclei possess a high cross section or probability for the capture of neutrons with thermal energies. The Rh^{104} formed by neutron capture is radioactive, and consists of two nuclear isomers (half-lives of 44 sec. and 4.3 min.). In nuclear physics experiments, a flux of neutrons can be conveniently and quickly measured by the determination of the amount of radioactivity induced in a thin rhodium foil, exposed for a few minutes to the neutrons. Another radioisotope, Rh^{106}, with a half-life of 30 sec., is the product of decay of Ru^{106} (*see* RUTHENIUM).

Rhodium always accompanies platinum in minerals, but only to a minor extent. It was first isolated from crude platinum by William Wollaston, who announced its discovery in 1804. He gave it the name rhodium in consequence of the red colour of a number of its compounds. Rhodium is almost as resistant as iridium to chemical attack by acids. The massive metal is not dissolved by hot concentrated nitric or hydrochloric acid or even by aqua regia which dissolves gold and platinum. The element dissolves in fused potassium hydrogen sulfate to yield a complex sulfate, soluble in water. Rhodium, in all well-characterized compounds, possesses the +3 oxidation state. Possibly some compounds of lower oxidation state can form, and strong oxidizing agents yield higher oxidation states of transient stability, probably +4 and +6. All its compounds are readily reduced or decomposed by heating to yield the powdered or sponge metal. Many rhodium compounds contain coordination complexes in which ammonia, water, chloride, or other groups are bonded covalently to a central rhodium ion (*see* CO-ORDINATION COMPOUNDS). Characteristically, the groups in these complexes are replaced slowly. A series of substituted ammine compounds is analogous to familiar compounds of cobalt. A yellow hydrous rhodium hydroxide, soluble in acid or alkaline solutions, can be precipitated, but some conditions will cause a black precipitate to form. Rh_2O_3 is a gray compound, insoluble in acids. $RhCl_3$ can be prepared in a form which does not dissolve in water or acids. Other forms dissolve readily to give solutions whose colour may range from brown to yellow and in which some or all of the chloride is not precipitated by silver nitrate. (D. S. MA.)

RHODOCHROSITE, one of the calcite group of carbonate minerals, consisting of manganese carbonate. It is used as

source of manganese for the ferromanganese alloys consumed in steelmaking and in the preparation of other manganese chemicals. Named from the Greek meaning "rose coloured," it sometimes is known as manganese spar.

The formula for rhodochrosite is $MnCO_3$. Extensive substitution of iron and calcium, as well as lesser amounts of magnesium, may occur in place of the manganese. It crystallizes in the rhombohedral system, and occurs commonly as compact crystalline masses and incrustations rather than as single crystals. When pure it is usually some shade of pink or rose-red, with a specific gravity of 3.7 and a hardness of 3.5–4.

Rhodochrosite is found in sedimentary deposits, in mineral veins of silver, lead, copper and zinc minerals formed at moderate temperatures and in high-temperature metamorphic deposits. It is found in England, at a number of localities in Europe, in Siberia and in Argentina, Brazil and Peru.

In the United States it occurs abundantly at Butte, Mont., and is found in California, Colorado, Nevada, Utah, Arkansas, Tennessee and Maine. (D. L. G.; X.)

RHODODENDRON, of the heath family (Ericaceae), is one of the largest genera of woody plants. It comprises 800–900

ROCHE

RHODORA (RHODODENDRON CANADENSE) BLOSSOMS

species including about 70 azaleas. Azaleas, together with rhodora, were once considered as constituting a distinct genus, but are now treated as species of *Rhododendron.*

The true rhododendrons are mostly evergreen and with campanulate corollas while the azaleas are usually deciduous and with funnelform corollas. They are commonly kept distinct by gardeners but botanical characters distinguishing the two are not constant. Some azaleas are evergreen while some true rhododendrons are deciduous.

Rhododendrons are among the most popular garden plants, much planted for their beautiful showy flowers and for their ornamental foliage in the evergreen species. The species are distributed throughout the colder regions of the northern hemisphere, and also on the high mountains of southern Asia, Malaysia and New Guinea, with one in northern Australia, but none in Africa and South America. The greatest development is found in the Himalayas eastward to western and central China, in the wet monsoon zone of Asia. There are about 26 species in North America, but none extending into Mexico.

There is no wild species in Britain, although *R. ponticum* is practically naturalized in the south, but the genus is exceedingly popular for gardens and most species do extremely well there. In North America they are best cultivated along the Atlantic seaboard, in the Alleghenies and on the Pacific coast.

The rhododendrons are shrubs, rarely small trees. Some species are epiphytic. The leaves are alternately arranged, stalked and, generally, with entire margins. The flowers are large and showy, on stalks, generally several to many grouped together in terminal umbellike clusters. There is a small calyx, generally five-parted. The corolla is red, blue, yellow or white, or of intermediate shades, rotate to campanulate or funnelform, usually slightly irregular, and five- or rarely six- to ten-lobed, occasionally divided to the base. There are five to ten stamens with anthers opening with apical pores. The ovary is 5- to 20-celled, each cell many ovuled. There is a slender style ending in an enlarged stigma. The fruit is an ovoid or elongate capsule, splitting from top into 5 to 20 valves when mature, liberating numerous minute seeds.

The species grow only in acid soils rich in humus. They thrive best in a cool, damp atmosphere and prefer "high shade." To prepare ground for cultivation, peat moss or acid leafmold, especially from oaks, or sawdust can be used to mix with loamy soil. The roots are shallow and are without root hairs but are associated with a mycorhizal fungus. It is important to mulch the soil to keep the roots from drying out in summer as well as in winter. The evergreen rhododendrons are generally propagated by seeds or layering. Grafting is resorted to in only the rarer and more tender kinds.

A number of American species are highly ornamental and much planted. Among these are the coast rhododendron, *R. macrophyllum,* the state flower of Washington; the catawba rhododendron, *R. catawbiense,* of the southern Alleghenies; and the rose bay rhododendron, *R. maximum,* of eastern North America. The latter two, together with the less hardy *R. arboreum* and *R. campanulatum* from the Himalayas, *R. caucasicum* from the Caucasus, *R. ponticum* from the Mediterranean region and other species, have given rise by hybridization to numerous horticultural varieties now in general cultivation. (H. L. L.)

RHODONITE, a member of the silicate group of minerals, consisting of manganese metasilicate. It commonly occurs as cleavable to compact masses with a rose-red colour; hence the name, from the Greek word meaning a rose. The formula is $MnSiO_3$. It crystallizes in the triclinic system and crystals often have a thick tabular habit; there are perfect cleavages parallel to the prism faces. The hardness is 5.5–6.5, and the specific gravity 3.4–3.68. Rhodonite is liable to alteration, and in certain cases forms the primary source of very important deposits of ores of manganese, mainly in the form of oxides, such as pyrolusite (*q.v.*); such are a considerable part of the manganese ores of India.

Rhodonite occurs as large rough crystals with franklinite and zinc ores at Franklin, N.J. Fine-grained rhodonite of clean colour is a desirable gem and ornamental stone. The finest quality is mined near Sverdlovsk, U.S.S.R., in the Urals. Good stone occurs in Siskiyou and Plumas counties in California. It has been used for beads, pendants and other ornaments. (W. F. Fg.)

RHONDDA, DAVID ALFRED THOMAS, 1st Viscount (1856–1918), British colliery owner and statesman, who was responsible for the introduction of food rationing during World War I, was born in Ysgyborwen, near Aberdare, Glamorgan, on March 26, 1856. He was the son of Samuel Thomas, a former grocer who subsequently became rich through colliery speculations. Educated at Caius College, Cambridge, Thomas joined the family coal business on his father's death (1879). In 1882 he married Sybil Margaret Haig. Liberal M.P. for Merthyr Tydfil from 1888 to 1910, and for Cardiff for a few months in 1910, he made no impact in politics, partly because of the dullness of his speeches, and from 1906 he devoted himself more and more to his coal business. His extraordinary commercial ability, his foresight, and the sympathy which he brought to bear on conditions in the mining industry made him the leading figure in industrial South Wales. His amalgamation of many mining companies, which made him very wealthy, culminated in 1913 in the formation of the huge combine, Consolidated Cambrian Ltd., which produced 6,000,000 tons of steam coal a year.

Between 1913 and 1915 he made several business visits to Canada and the United States. Returning to England in 1915, Thomas

and his daughter Margaret both narrowly escaped death when the "Lusitania" was sunk on May 7. Immediately afterward Lloyd George, then minister of munitions, sent Thomas back to the United States to organize the supply of American munitions to England (July–December 1915). Created Baron Rhondda in January 1916, he took office in Lloyd George's ministry as president of the local government board in December and was appointed controller at the food ministry in June 1917. Taking stern measures to end the speculation in food, he gradually fixed prices, controlled supplies, and from February 1918 introduced the system of compulsory food rationing. Created a viscount in June, he died at Llanwern, Monmouthshire, on July 3, 1918.

By special remainder he was succeeded to the viscountcy by his only child MARGARET HAIG THOMAS (1883–1958), political journalist and a supporter of rights for women, who was born in London on June 12, 1883. She was an active suffragette before World War I and underwent a short term of imprisonment. Shortly after her marriage to Humphrey Mackworth (later 7th baronet) in 1908, she became her father's personal assistant in his colliery concerns and throughout her life remained an active business woman in the coal industry. After succeeding to the title, for many years she unsuccessfully fought for the right of women to sit in the House of Lords. She was chiefly responsible for the founding of the weekly newspaper *Time and Tide*, which she edited for the last 30 years of her life, and established as a leading weekly. She died in London on July 20, 1958. Her books include an autobiography, *This Was My World* (1933), and a biography of her father, *D. A. Thomas, Viscount Rhondda* (1921).

RHONDDA, a municipal borough (1955) of Glamorgan, south Wales, 12 mi. (19 km.) long by about 4¾ mi. (7 km.) across at its widest part, comprising two main valleys, named after their respective rivers, Rhondda Fawr and Rhondda Fach. Pop. (1961) 100,287. Area 37.3 sq.mi. (96.6 sq.km.). The valleys are deeply incised in the coal measures of the south Wales geological basin and their lateral boundaries are formed by hills varying from 560 ft. (171 m.) near Trehafod to 1,567 ft. on the northeast of Maerdy in the Rhondda Fach and 1,742 ft. on the southwest of Treherbert in Rhonnda Fawr. The upper end of the latter valley rises to the Rhigos plateau where Craig-y-Llyn (1,969 ft. [600 m.]) is the highest point in Glamorgan. The two valleys are separated by the ridge of Cefn-y-Rhondda, which ranges from 600 ft. above Porth to 1,690 ft. There are tributary valleys where it joins the Rhigos plateau of which Cwmparc, Clydach vale and Cymmer are the chief.

Rhondda is the centre of the eastern division of the south Wales coal field. Coal exploitation there started in 1807 and so it was later than that of the northern sections of the south Wales area where coal was worked early for iron smelting. It was the realization of the steam-raising properties of the Rhondda coal and the opening of the Treherbert pits in 1855 that made the region famous.

With the great demands made for steam coal by the ever increasing railway traffic, steamship services and navies of the last half of the 19th century, Rhondda was transformed from being a purely pastoral upland region into a densely populated industrial area. No thought was given then, however, to the development of other industries which could provide alternative employment in the event of a setback in the coal-mining industry. With the rapid growth of each township provision was made for miners' libraries and institutes and numerous places of worship, and around these grew and flourished social, religious and cultural activities, particularly in music and drama, which, in turn, led to the creation of a strong community of interest and civic pride.

In 1801 the population was 542, but by 1871 it had reached 23,950; in 1881 it was 55,632 and in 1901 it was 113,735. The peak population figure was 167,900 in 1924 but during the severe industrial depression of the 1930s it fell to 121,940 by 1938. Further migration during World War II reduced the population seriously and by 1951 the figure stood at 111,389.

With the development of the coal exporting trade a number of small railway companies connected Rhondda with Cardiff, Port Talbot and Swansea but all these lines were eventually merged in the Great Western railway, and in 1947 the Western region of British railways. The slump in world demand for Welsh coal following World War I undermined the prosperity of the area and led to mass unemployment and migration. In 1934, of Rhondda's 61,460 insured men more than 47% were without work. In an attempt to relieve this critical situation two new factories were opened in the area in 1939. After World War II the policy of redistribution of industry to help depressed areas brought new industries to Rhondda, and at mid-century the area had a stable and varied industrial pattern. (J. C. G. J.)

RHÔNE, a *département* of east-central France, formed in 1793 from the eastern portion of the *département* of Rhône-et-Loire, and chiefly comprised of the old districts of Beaujolais and Lyonnais (*q.v.*). It lies west of the Saône and Rhône rivers above and below their confluence at Lyons but also includes a small area to the east around the city. The *département* is bounded north by Saône-et-Loire, east by Ain and Isère, and southwest and west by Loire. Area, 1,104 sq.mi. (2,859 sq.km.); pop. (1962) 1,116,664.

Rhône consists largely of broken highlands, with summits about 3,000 ft. (914 m.), in the eastern part of the Massif Central and built of granite, gneiss, and schists that weather to give only poor soils. There is better farmland in the Rhône-Saône Plain, where wheat, maize (corn), sugar beet, and fodder crops are grown. The lower slopes of the hills flanking the Saône Valley in Beaujolais are an important vine-growing district, with Villefranche the local market centre. Iron pyrites are worked at Sain-Bel and Bully, but Rhône has little mineral wealth. It owes its importance and large population to Lyons (*q.v.*) and the great industrial development centred there, especially concerned with silk textiles, and now with man-made fibres also. The whole *département* comes under the domination of Lyons, and there are scattered factories and workshops in the countryside, with tentacles of more intense industrialization along the main routes. Tarare, on the road and railway from Lyons northwest to Roanne, is especially concerned with making velvet, plush, and mixed fabrics. In the extreme south, the Saint-Étienne coal field extends into the *département* along the valley of the Gier, and Givors, at its confluence with the Rhône, has heavy metallurgical and glass industries as well as textile mills. Lyons is the *préfecture*, centre of an archbishopric and of an educational division (*académie*), and has the court of appeal. Rhône is divided into two *arrondissements*, centred upon Lyons and Villefranche. (AR. E. S.)

RHÔNE RIVER, one of the most important rivers in Europe and the main one flowing from that continent directly into the Mediterranean. It rises at the eastern extremity of the Swiss canton of the Valais, flows through Switzerland and France, and enters the Mediterranean at the Gulf of Lyons. Its total length is 505 mi. (812 km.), of which the Lake of Geneva (Lac Léman), through which it flows, claims 45 mi. (72 km.); and its total fall is 5,898 ft. (1,798 m.). Its course (excluding the Lake of Geneva, *q.v.*) falls naturally into four divisions: (1) from its source to the Lake of Geneva (105½ mi. [170 km.] and fall 4,679 ft. [1,426 m.]); (2) from Geneva to Lyons (124 mi. [200 km.] and fall 689 ft.); (3) from Lyons to Arles (200 mi. [321 km.] and fall 530 ft.); and (4) the delta, from Arles to the Mediterranean (30 mi.).

From Its Source to the Lake the Rhône is a purely Alpine river, flowing through a great glacially deepened trench, first in a synclinal structure between the Aare and Saint-Gotthard massifs, then along the front of the Pennine nappes. (*See* ALPS.) It issues as a torrent, at the height of about 5,909 ft. (1,801 km.), from the Rhône glacier at the head of the Valais. It is almost immediately joined (left) by the Mutt torrent, coming from a small glacier, and then flows past the Gletsch Hotel (where the roads from the Grimsel Pass and the Furka Pass unite). About half a mile from the glacier the river descends through a wild gorge to the more level valley, to reach the first village, Oberwald. It preserves a southwesterly direction till Martigny.

The uppermost valley of the Rhône is named Goms, its chief villages being Münster and Fiesch. The river there is swollen by mountain torrents, descending from the glaciers on either side: by the Geren (left), near Oberwald; by the Eginen (left), near Ulrichen; by the Fiesch (right), from the Fiesch glacier, a

Fiesch; by the Binna (left), near Grengiols; by the Massa (right) from the Aletsch glaciers, above Brig. At Brig the Rhône has descended 3,678 ft. (1,121 km.) from its source in 28 mi. (45 km.), and is already a considerable stream when joined (left) by the Saltine, descending from the Simplon Pass. Its course below Brig is less rapid and lies through wastes of alluvial deposits. The valley is wide and marshy, the river frequently overflowing its banks. Further mountain torrents fall into the Rhône: these are the Visp (left) from the Zermatt Valley, at Visp; at Gampel, the Lonza (right) from the Lötschen Valley; at Leuk, the Dala (right) from the Gemmi Pass; at Sierre, the Navizen (left) from the Einfisch or Anniviers Valley; at Sion, the capital of the Valais, the Borgne (left) from the Val d'Hérens; below Sion, by the Morge (right), from the Sanetsch Pass; and at Martigny by the Drance (left) from the Great St. Bernard and the Val de Bagnes. At Martigny the flat-floored trench is nearly 2 mi. (3 km.) wide, but from there the river bends sharply to the northwest toward the Lake of Geneva, its glaciated valley narrowing markedly as it cuts across the structures. Opposite Dorénaz it receives the Salanfe (left). Immediately below St. Maurice the Rhône rushes through a narrow and striking defile which commands the entrance of the Valais.

The river then enters the wide alluvial plain, formerly occupied by the southeastern arm of the Lake of Geneva. It receives at Bex the Avançon (right) flowing from the glaciers of the Diablerets Range, at Monthey the Vièze (left) from Champéry and the Val d'Illiez, and at the Aigle the Grande Eau (right), from the valley of Ormonts-dessus. It passes Port Valais, once on the lake, before emptying through a delta into the Lake of Geneva, between Villeneuve (right) and St. Gingolph (left).

The upper Rhône, being fed by glacial streams, has three times more flow in summer than in winter and is overburdened with sediment, much of which is deposited along the course, the remainder settling down in the Lake of Geneva, in the blue waters of which it is possible to follow the whiter course of the stream for some distance before it disappears. During all this portion of its course the Rhône is not navigable, but its valley forms an artery into the Alps which is followed by the railways and roads.

THE RHÔNE RIVER AND ITS TRIBUTARIES

From Geneva to Lyons.— About ½ mi. below Geneva the Rhône is joined by the Arve (left) from the glaciers of the Mont Blanc Range. About 12 mi. (19 km.) S of Geneva the Rhône enters France. The river between the Lake of Geneva and its confluence with the Ain cuts transversely across the folds of the southern Jura, breaking through them in a series of zigzags by means of narrow gorges or *cluses*. After surging through the deep gorge Défilé de l'Écluse about 25 mi. (40 km.) SW of Geneva, at Bellegarde the Rhône is joined by the Valserine from the north and the river swings in a southerly direction. Below Bellegarde it flows in a steep-sided cleft providing the site for the Génissiat Dam which creates a narrow 14-mi.-long lake for hydroelectric power production. Above Seyssel the Usses (left) joins the Rhône, while just below that village the Fier (left) flows in from the Lac d'Annecy; from there the channel of the river widens and the hills diminish in height. The waters of the Lac du Bourget are linked with the Rhône by the Short Canal de Savières.

The river continues southward until joined, near Corbelin, by the Guiers (left) from the Grande Chartreuse Mountains, and from there swings around the southern spur of the Juras. The Geneva-Paris railway follows the river as far as Culoz before turning due west to Lyons. Some way below Bellegarde at Le Parc, 95 mi. (153 km.) above Lyons, the Rhône becomes officially "navigable," although down to Lyons the navigation consists almost entirely of flat-bottomed boats and rafts, the average depth being no more than one metre. The last of the *cluses* is at the Pont du

Saut or Sault, just south of Lagnieu, from where the river enters the Plain of Bresse. The river there widens and before its regulation by the Canal de Jonage and the Canal de Miribel much of the surrounding countryside was liable to inundation.

About 20 mi. (32 km.) above Lyons the Rhône receives the Ain (right), which descends from the French slope of the Jura. At Lyons the Rhône makes its junction with the Saône, flowing from the north. The Saône (*q.v.*), which has received the Doubs (left), is the real continuation of the lower Rhône, both from a geographical and a commercial point of view. It is by means of canals branching off from the course of the Saône that the Rhône communicates with the basins of the Loire, Seine, Rhine, and Moselle.

From Lyons to Arles.—It is here that the Rhône becomes one of the great historical rivers of France. It was up its valley that various civilizations penetrated from the Mediterranean. This stretch of the Rhône provides a narrow north-south corridor between the abrupt eastern edge of the Massif Central and the western foothills of the French Alps. The river flows alternatively through narrow gorges and open basins, a sequence owing much to the Alpine earth movements. Rapids occur in some of the gorge sections, hampering navigation. The steepest gradient lies between the confluence of the Isère and that of the Ardèche. Most of the tributary streams in this section of the Rhône's course join it from the Alpine region to the east; the Ardèche is the only considerable affluent from the Massif Central. The left bank, followed by both road and rail, serves as a great medium of commerce by which central France sends its products to the sea, and possesses such historical cities as Vienne, Valence, Avignon, Tarascon, and Arles. It receives the Isère, Drôme, Aygues, and Durance rivers, all formed by the union of many streams from the Dauphiné Alps. Completed in 1956, a 17-mi. (27 km.) canal parallels a turbulent stretch of the river from Donzère, south of the plain of Montélimar, to Mondragon, near Pont-Saint-Esprit, easing navigation and providing an 85-ft. head of water for a hydroelectric station near Bollène. Below Mondragon the floor of the valley becomes marshy, the river channel more braided, and drainage ditches increasingly score the floodplain as the market gardening area around Avignon is reached.

The average depth of channel between Lyons and Arles is 5 ft. (1.6 m.) but the series of rapids and the river's irregular regime have not favoured the commercial development of the waterway, for upstream navigation is difficult. Over 1,000,000 tons of traffic is borne annually by this stretch of the river, but much of this traffic is local. Powerful tugs and motor barges with skilled pilotage are needed to make headway against the current. Since World War II large civil engineering schemes have been undertaken to harness the river for electricity and to canalize or bypass the more difficult sections (such as the Donzère-Mondragon Canal), so that eventually the river may offer a new route for merchandise between the Mediterranean and the North Sea.

From Arles to the Mediterranean.—The delta extends from near Arles, about 25 mi. (40 km.) from the sea where the river divides into two main branches. These are the Grand Rhône, flowing southeast to meet the sea at Port-Saint-Louis-du-Rhône, and the Petit Rhône which flows southwest into the sea at the small resort of Les Saintes-Maries-de-la-Mer. The delta plains consist of the Crau and the Camargue. The Crau, between the Grand Rhône and the Alpine foothills, is composed of coarse detritus. Much of this area is too dry for cultivation and is given over to sheep pasture. The Camargue, between the two branches of the Rhône, is the delta proper, and provides a landscape of rough pasture, marsh, lagoons, and, alongside the rivers and canals, patches of cultivated land. Many thousands of acres have been leveled for rice cultivation, while a considerable area including the large Étang de Vaccarès has been set aside as a nature reserve. The coast of the delta is nearly 50 mi. (80 km.) in length and consists of a series of sandy bays, the dunes backing onto a labyrinth of reedy marshes and lagoons. Several canals have been constructed from the vicinity of Arles, linking the Rhône with Marseilles, Port-de-Bouc, and Sète. Post-glacial oscillations of sea level, the great load of detritus brought down by the river, and the small tidal effect in the Mediterranean account for the delta formation which is still slowly growing seaward, its shape modified by the east-west longshore drift.

The regime of the river reflects its Alpine origin and that of most of its tributaries, since it rises to a maximum with the snow melt of early summer and shows a second peak with the increasing rainfall of autumn. Freezing of the Alpine tributaries reduces considerably the winter flow. The Lake of Geneva helps to regulate and clarify the upper Rhône. Immediately below Lyons the flow is more even because of the greater winter volume of the Saône, but from the Valence Basin southward the Alpine character of the left-bank tributaries is again noticeable in the flow of the main river.

The principal commodities carried on the waterway are, southward, *vin ordinaire* for export, bauxite, and, locally, sand and gravel for construction work. Petroleum products, fertilizers, and Algerian wine provide the major northward cargoes.

By 1964 the French had harnessed one-half of the Rhône's potential hydroelectric power by means of an integrated series of works, the largest being at Génissiat (installed capacity 400,000 kw.), Montélimar, Baix, and the André-Blondel power station near Bollène (installed capacity 300,000 kw.).

See also references under "Rhône River" in the Index.

(A. B. M.)

RHUBARB. This name is applied both to a drug and to a vegetable.

Drug.—The drug has been used in medicine from very early times, being described in the Chinese herbal *Pen-king*, which is believed to date from 2700 B.C., and it is still produced in the four northern provinces of China in modern times. In England the culture of rhubarb for medicinal purposes began in 1777 at Banbury in Oxfordshire and continued to be carried on there.

Two varieties of the drug are known, viz., kiln dried and sun dried. So-called Turkey rhubarb was the Chinese drug which reached Europe from Aleppo and Smyrna, having traveled to Asia Minor by way of Persia and the Caspian.

The most important constituent of this drug, giving it its purgative properties and its yellow colour, is chrysarobin, formerly known as rhein or chrysophan. The rhubarb of commerce also contains chrysophanic acid.

Nearly 40% of the drug consists of calcium oxalate, which gives it the characteristic grittiness. There is also present rheotannic acid, which is of some practical importance. There are numerous other constituents, such as emodin, mucilage, resins, rheumic acid, aporrhetin, etc.

Vegetable.—The vegetable rhubarb (*Rheum rhaponticum*), also called pieplant (family Polygonaceae), is a hardy Asiatic perennial grown for its large, succulent leafstalks. The plant produces large clumps of enormous leaves, up to two feet across, on proportionately large petioles or leafstalks—an inch or more in diameter and up to two feet or more in length—that arise from a shortened underground stem. These huge leaves arise early in the spring; later in the season a large central flower stalk may appear and bear numerous small greenish-white flowers and three-angled or winged fruits containing one seed. The plant is best adapted to the cooler parts of the temperate zones; the roots are quite hardy to cold although the tops are killed in autumn.

J. HORACE MCFARLAND COMPANY

RHUBARB (RHEUM RHAPONTICUM) IN FLOWER

Rhubarb seed does not produce plants true to the variety that bears them; therefore it is propagated by dividing the perennial "crown" into pieces each consisting of a root piece and a bud. These are set in the field about four or five feet apart each way. The large crowns are sometimes moved into forcing houses in late winter for producing the leaf

stalks under artificial heat, and in subdued light. A greenhouse is not necessary. Only the fleshy leafstalks are eaten; they are highly acid and contain considerable amounts of oxalates. The leaves should never be eaten since they are sometimes poisonous. (J. M. Bl.)

RHYL, an urban district of Flintshire, Wales, lies 18 mi. (28 km.) WNW of Flint by road at the mouth of the River Clwyd. Pop. (1961) 21,737. Rhyl has developed since the mid-19th century from a small fishing town to a thriving seaside resort. It is popular with family parties because of its safe, sandy beaches. On the 3½-mi. (6 km.)-long promenade is the domed pavilion with a theatre seating 1,100 persons, and the all-glass Royal Floral Hall. The town's oldest building, known as T'yn Rhyl, dates from 1608. There are two parks: the Botanical Gardens (opened 1928) and the King George V Coronation Gardens for outdoor sports (opened 1937). The main industry is tourism, but steel, rayon, and glass factories, and the coal mines are nearby. (G. H. Wi.)

RHYME (Rime), that phenomenon which occurs when two or more words with similarly sounding final syllables are so placed as to echo one another. Though normally used at the end of a line to make it chime with the end of another line, and termed "end rhyme," it can also be used in other positions, as in leonine verse (*q.v.*). In premature rhyme one rhyming word is at the end of the line and the other is not, thus causing the rhyme to occur ahead of expectation. Suspended rhyme occurs when the second, or rhyming, word has two rhyming syllables, one roving over to the next line; *e.g.*, ". . . tenfold/. . . men,/Bold. . . ."

Masculine rhyme occurs when the two words end with the same vowel-consonant combination (*e.g.*, "stand"/"land"). Feminine rhyme has two rhyming syllables (*e.g.*, "profession"/"discretion"). Trisyllabic rhyme has three (*e.g.*, "patinate"/"latinate"). These, all called "true rhymes," are the only varieties acceptable to purists, though poets have often been less particular. The device of para-rhyme, first identified and used systematically by Wilfred Owen (*q.v.;* 1893–1918), is a rhyme in which the two syllables have different vowel sounds but identical penultimate and final consonantal groupings (*e.g.*, "grand/"grind"). Feminine para-rhyme has two forms, one in which both vowel sounds differ, and one in which only one does (*e.g.*, "ran in"/"run on"; "blindness"/"blandness"). Weakened, or unaccented, rhyme, occurs when the relevant syllable of the rhyming word is unstressed (*e.g.*, "bend"/"frightened"). Because of the way in which lack of stress affects the sound, a rhyme of this kind may often be regarded as consonance, which occurs when the two words are similar only in having identical final consonants (*e.g.*, "best"/"least").

Another form of near rhyme is assonance, in which only the vowel sounds are identical (*e.g.*, "grow"/"home"). Many folk-poems and nursery rhymes use assonance, and French poetry of the 12th century and earlier used it rather than rhyme. The *Chanson de Roland* (*see* Roland, Chanson de) is a notable example of assonantal structure, as all the lines in each stanza end with the same vowel sound. Assonance continues to dominate poetic technique in the Romance languages, especially Spanish, but performs only a subsidiary function in the verse of the English-speaking world. The two main advantages of its use in English verse derive from its ability to facilitate smooth rove-overs from line to line, there being no overemphatic chime to suggest a jarring conclusiveness, and to suggest a casual ease and, even, lack of sophistication. Thus, in the earliest and best-known version of the nursery rhyme "Ding Dong Bell" we are partly persuaded of its childlike simplicity by the assonance of "in" with "Green": "Who put him in?/Little Tommy Green." In general, use of end-assonance in a poem increases its fluidity.

Subtlety is often given to a poem by occasional use of assonance and other forms of near-rhyme, as well as by unstressed rhyme, in which the two syllables are not accentuated (*e.g.*, "ever"/"killer"). The rather harsh effect of a masculine rhyme can also be softened by using trailing or semi-rhyme, in which one of the two words trails an additional unstressed syllable behind it (*e.g.*, "trail"/"failure"). At the opposite end of the scale is rime riche, which, first used extensively by Victor Hugo, is commoner in French than in English poetry. It occurs when the two words are identical in appearance, but not in meaning; thus it could occur as the consequence of manipulating the different meanings of *e.g.*, "foil" (= "metal" and "thwart"), and "leaves" (= "foliage" and "departs").

Many traditional verse forms depend upon set rhyme patterns. The main stanza forms are ottava rima, terza rima, the Spenserian stanza, rime royal, the quatrain (*qq.v.*), the heroic couplet (*see* Couplet), and the Burns's stanza (or metre), an arrangement of six lines, with 8, 8, 8, 4, 8, and 4 syllables, rhyming *aaabab,* first found in 11th-century Provençal lyric poetry, and used in English late 14th- and early 15th-century miracle plays, but preserved only in Scotland and used with consummate skill by Robert Burns. The main poetic forms depending upon set rhyme patterns are the sonnet, villanelle, rondeau, ballade, chant royal, triolet, canzone, and sestina (*qq.v.*): the last two are only rhymed poems inasmuch as the repetition of the same end-words in successive stanzas produces a rhyming effect.

Rhyme seems to have developed as a combination of earlier techniques of end-consonance, end-assonance, and alliteration (*see* Alliterative Verse). It occurs only occasionally in classical Greek and Latin poetry, but more frequently in medieval religious Latin verse, and in songs from the 4th century A.D. onward. Periodically opposed by devotees of the ancients, such as Gabriel Harvey (*q.v.;* 1550?–1630), and by 20th-century advocates of so-called free verse (*q.v.*), it has never fallen into complete disuse.

RHYOLITE, the volcanic, mostly effusive, equivalent of granite, takes its name from the Greek word for torrent or stream because of the frequency and variety of its fluxional textures. The term liparite, from the Lipari Islands of Italy, originally proposed for the same rocks, was subsequently restricted to porphyritic varieties and is rarely used.

The glassy rhyolites include obsidian, pitchstone, perlite and pumice, though microscopic examination sometimes shows that pumices are actually ash flows and thus better designated as tuffs.

At atmospheric pressure granitic liquid above its melting point is exceedingly viscous. Cooled rapidly, as when extruded from a volcanic vent, it tends to chill to a glass rather than crystallize, as under plutonic conditions. The glassy or partly glassy rocks so formed are metastable, however, and devitrify into minutely crystalline, frequently spherulitic or felted aggregates, in periods of time that are relatively short by geological standards. Hence pre-Tertiary rhyolites which were originally true glasses almost invariably display one of the vitrophyric, stony or felsitic textures characteristic of devitrification. The glasses are also especially susceptible to hydrothermal alteration and weathering.

Most rhyolites are porphyritic, indicating that crystallization had begun prior to extrusion. Indeed, intratelluric crystallization may sometimes continue until the rock consists largely of phenocrysts at the time of extrusion, and the amount of microcrystalline matrix in the final product may then be so small as to escape detection except under the microscope. Such rocks (nevadites) are easily taken for granite in hand specimens.

In most rhyolites, however, the period of intratelluric crystallization is relatively short, so that the rock consists largely of a microcrystalline or partly glassy matrix in which are set a few per cent of phenocrysts. The matrix is sometimes micropegmatitic or granophyric.

Composition.—Except for occasional gross enrichment in silica, usually due to hydrothermal alteration, the chemical composition of rhyolite is very like that of granite (*q.v.*). There can be little doubt of the equivalence, and this is perhaps the strongest single reason for supposing that at least some and probably most granites are of magmatic origin.

The phenocrysts of rhyolite may include quartz, alkali-feldspar, oligoclase, biotite, amphibole or pyroxene, and the rules governing the coexistence of the different species are similar to those obtaining in granite. Thus, if an alkali-pyroxene or alkali amphibole is the principal dark mineral, oligoclase will be rare or absent

and the feldspar phenocrysts will consist largely or entirely of alkali-feldspar. Rocks of this sort, for which the names comendite and pantellerite have been proposed (the latter has priority), are the volcanic equivalents of the alkali-granites.

If both oligoclase and alkali-feldspar are prominent among the phenocrysts the dominant dark silicate will be biotite, and neither amphibole nor pyroxene, if present, will be an alkaline variety. Such lavas, the quartz porphyries or "true" rhyolites of most classifications, are the volcanic equivalents of the two-feldspar granites.

Certain differences between rhyolite and granite should not be glossed over. Muscovite, a common mineral in granite, occurs very rarely and only as an alteration product in rhyolite. In most granites the alkali-feldspar is a soda-poor microcline or microcline-perthite. In most rhyolites the alkali-feldspar is sanidine, thought to be a high-temperature form, and not infrequently rich in soda.

A great excess of potassium oxide, K_2O, over sodium oxide, Na_2O, is uncommon in granite except as a consequence of hydrothermal alteration; it is not uncommon in rhyolites, and though it sometimes seems to be produced in the same way, this is by no means always the case.

Occurrence.—Rhyolites are known from all parts of the earth and of all geologic ages, though the pre-Tertiary ones are ordinarily so devitrified or otherwise altered as to receive special names, viz., felsite, quartz-keratophyre, quartz-porphyry, etc. Obsidian is well developed in Yellowstone National park, Mont., and Mono craters, Calif. The classic localities for perlite are in Hungary, and pitchstone is perhaps best known from Arran, Scot. Pumice is of world-wide occurrence. Porphyritic rhyolites showing every ratio of phenocrysts to matrix abound in Colorado and Nevada. The pantellerites are spectacularly developed on the island of Pantelleria, southwest of Sicily, but are found throughout the Mediterranean, in East Africa, eastern Siberia, Indonesia and west Texas.

Plagioclase and biotite are rare or lacking as phenocrysts in these rocks and in many of them quartz phenocrysts are not common. Quartz is usually abundant in the groundmass, however, and the silica content is generally appropriate for a granite or quartz syenite. The ferromagnesians are alkali amphiboles and pyroxenes, cossyrite (evidently a titaniferous amphibole) and, occasionally, fayalite.

Fractional Crystallization Hypothesis.—It is known that granites are confined to continental areas and the association can hardly be fortuitous. Rhyolites are for the most part also confined to the continents or their immediate margins, but they are not entirely lacking elsewhere. Small quantities of rhyolite (or quartz trachyte) have been described from the Marquesas Islands, Tonga, Hawaii, Gambier, Samoa Islands, St. Helena and Ascension, all genuine oceanic islands remote from any continental land-mass. There seems no way to explain such occurrences except as residual liquids from the fractional crystallization of basalt, and they are the clearest kind of evidence that granitic magma may indeed form in this fashion. Furthermore, on the continents proper and on continental islands, there is often a close and quite possibly genetic association between basalt, andesite and rhyolite. Sardinia and the Lipari Islands in the Mediterranean offer excellent examples of this association, as do Steens mountain and Newberry volcano in Oregon.

If the ratio of rhyolite to basalt in the oceanic islands is any criterion of the efficiency of the fractionation process, however, the derivation of the known or reasonably inferred volume of granite in the continents by this means would require an almost unimaginably immense volume of basaltic magma. Granting that this amount of basalt was available, and that it did indeed fractionate during cooling to yield granite magma, it must yet be explained why rhyolites should be so much less abundant than granites.

The derivation of granitic and rhyolitic magma by fractional crystallization of basalt is the most reasonable working hypothesis available; it is nothing more.

For additional information respecting the special characters and the occurrences and uses of the more important rhyolites *see* OBSIDIAN; PERLITE; PITCHSTONE; PUMICE. More detailed discussion of fractional crystallization will be found in PETROLOGY: *Plutonic Complexes*. *See* also GEOCHEMISTRY: *Geochemistry of the Lithosphere: Crystallization of Magmas and Its Products*.

(F. Cs.)

RHYS, ERNEST PERCIVAL (1859–1946), English man of letters, who, as editor of Everyman's Library, a series of inexpensive editions of world classics launched in 1906, influenced the literary taste of his own and succeeding generations of readers. He was born on July 17, 1859, in London, and spent his early years in Carmarthen and Newcastle upon Tyne. Ill-health interrupted his education but he showed early promise and an innate love of books. In 1886 he settled in London as a free-lance poet and critic. He contributed to reviews and to the two volumes published by the Rhymers' Club of which he, with W. B. Yeats, was a founder-member, and was employed by various publishers as an editor. In 1891 he married Grace Little (d. 1929), who, herself a writer, encouraged his literary interests; their home in Hampstead became a meeting place for the literary men and women of the time. His association with the publisher J. M. Dent began with his editing a series of lyric poets (1894–99), and in 1904 Dent invited him to edit Everyman's Library (a title suggested by Rhys). The first volume came out in 1906, and by the time Rhys died (on May 25, 1946), of the 1,000 volumes planned, 983 had been published. Rhys's own writings included volumes of essays and poems, one of his best-known poems being "The Leaf Burners," and two volumes of reminiscences, *Everyman Remembers* (1931) and *Wales England Wed* (1940).

(E. F. Bo.)

RHYTHM (Greek *rhythmos*, derived from *rhein*, "to flow") is, in its most general sense, an ordered alternation of contrasting elements.

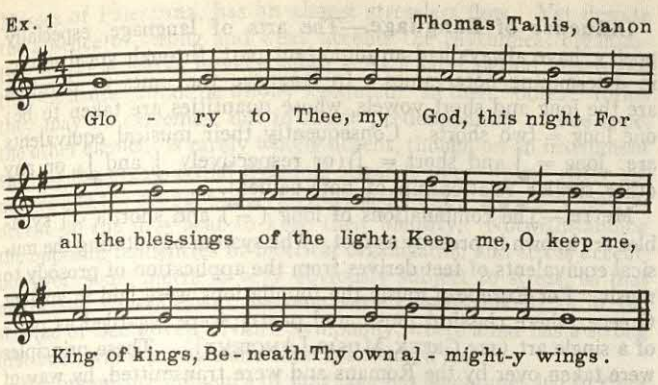
Attempts to define rhythm in music and poetry have produced much disagreement, partly because rhythm has often been identified with one or more of its constituent but not wholly separate elements, such as accent, metre, tempo. As in the closely related matters of verse and metre, opinions differ widely, at least among linguistic theorists, on the nature and movement of rhythm. Theories requiring "periodicity" as the *sine qua non* of rhythm are opposed by theories which, taking a wider view of rhythm, include in it even nonrecurrent configurations of movement, as in plainsong or prose. Difficulties arise from attempts to interpret the rhythms natural to one language in terms of another; *e.g.*, prosodists have tried to relate the rhythmic principles of the Germanic languages (including English) to those developed in classical Greek and Latin, and in the Romance languages. Moreover, the connection between linguistics and rhythm has not always been fully recognized.

The following analysis principally concerns rhythm in music, although comparative references are made to verse and prose. For a more detailed discussion of the linguistic and literary aspects of English rhythm, *see* METRE and VERSE; for Greek and Latin verse metres, *see* PROSODY, CLASSICAL. For dance rhythms as such, *see* DANCE and related articles. *See* also references under "Rhythm" in the Index.

Rhythm is the force underlying the structure of all music, since a musical work is a composition in time (as contrasted with a painting or a piece of sculpture, which is a composition in space). It is the one indispensable element of music: rhythm can exist without melody, as in the drumbeats of primitive music, but melody cannot exist without rhythm. In music which has both melody and harmony the rhythmic structure, moreover, cannot be wholly separated from the melodic and harmonic structures. Plato's observation that rhythm is "an order of movement" (*kinesis taxis*) provides a convenient starting point for an analysis of the nature of rhythm. The first task is to discover the elements of which this order is composed.

Beat.—The unit division of musical time is called a beat. Just as we are aware of the body's steady pulse, or heartbeat, so in composing, performing, or listening to music we are instinctively aware of a periodic succession of beats. No matter whether each beat be sounded (as in Ex. 1) or not (as in the other examples) we feel its constant underlying presence.

Ex. 1 Thomas Tallis, Canon



Tempo.—The pace of the fundamental beat is called tempo (Ital., "time"). The expressions "slow tempo" and "quick tempo" suggest the existence of a normal tempo. What we instinctively feel to be a normal tempo is one built on a pulse of 60 to 80 beats per minute—a range comparable with that of the heartbeat (72 per min.) or man's natural walking pace (76 to 80 paces per min.). The expression of tempo as a given number of beats to the minute resulted from the work of Johann Maelzel who, in 1816, perfected the metronome (*q.v.*). A piece of music in which the beat runs at 64 to the minute may thus carry the indication at the opening of the score, ♩ = 64, together with a less precise but more suggestive verbal indication, such as *andante moderato*. In practice the slow and fast extremes of tempo are built on pulses of 32 and 128 beats to the minute; *i.e.*, half of and double the normal 64. These pulses represent the practical limits of a conductor's beat. Modern metronomes extend to 208 beats per minute, but such beats are felt to be sub-beats of longer units in a slower tempo. The tempo of a piece of music indicated by a composer is, however, neither absolute nor final. In performance it is likely to vary, according to the performer's interpretative ideas or to such considerations as the size and reverberation of the hall, the size of the ensemble, and, to a lesser extent, the sonority of the instruments. A change of tempo within such limits does not affect the rhythmic structure of a work.

Rubato.—The tempo of a work is never inflexibly mathematical. It is impossible to adhere in a musical manner to the metronomic beat for any length of time. In a loosely knit passage a tautening of tempo may be required; in a crowded passage a slackening may be needed. Such modifications of tempo, known as *tempo rubato*—*i.e.*, "robbed time"—are part of the music's character. Rubato needs the framework of an inflexible beat from which it can depart and to which it must return. In fact, true rubato never passes the point where the exact basis can no longer be perceived through the inexact. Moreover, it cannot alter the rhythmic organization of the work; it is an essential part of it. Rubato, being essentially a matter of instinct, is rarely written as a direction in musical scores. Chopin, however, uses the term in his Mazurka, Op. 24, No. 2. *Tempo rubato* is illustrated in the above passage from Brahms' *Variations on a Theme of Haydn* (Ex. 2), where a pressing-on in bar four is compensated by a slackening in bar five, before the subject passes to the violins.

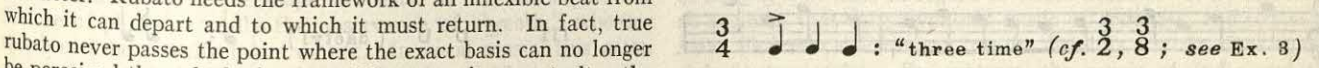
Ex. 2

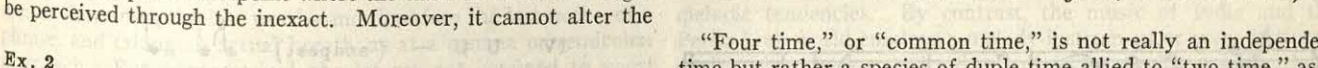
Accent by Stress.—Music is not built on steady, unemphasized beats. The mind seeks some organizing principle, and, if one is not actually present, it imposes a grouping of its own. Experiments show that regular and identical sounds are instinctively grouped by the mind into twos or threes, with a stress on every second or third beat. The mind thus creates, from a monotonous series, a regular succession of strong and weak beats.

Time.—In music such grouping is achieved by actual stress; *i.e.*, by periodically making one note stronger than the others. When the stress occurs at regular intervals the beats fall into natural time-measures. Though in European music the concept of time-measures reaches back to a remote age, only since the 15th century have they been indicated by means of bar-lines, and the period within them was first called a bar in William Bathe's *A Brief Introduction to the True Art of Music* (1584).

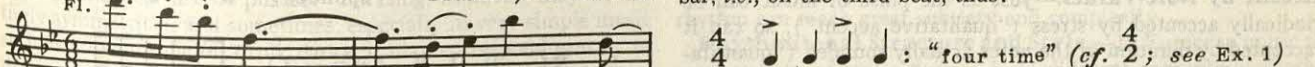
The length of each beat in a bar may be a time-unit of short or long duration. The time-measure is indicated at the opening of a piece by a time signature; *e.g.*, $\frac{2}{4}, \frac{4}{8}, \frac{3}{4}, \frac{6}{8}$. The lower numeral (always a multiple of 2) indicates the time-unit of the beat ($1 = \mathbf{o}$, $2 = \mathbf{d}$, $4 = \mathbf{♩}$, etc.); the upper numeral is the number of these time-units in the bar. The principle of time signature is illustrated in the following table:

The two basic types of time-measure are notated by bars of two or of three beats:





"Four time," or "common time," is not really an independent time but rather a species of duple time allied to "two time," as it can hardly be thought of without a subsidiary stress at the half-bar, *i.e.*, on the third beat, thus:



Duple, triple, and quadruple time-measures, *i.e.*, those in which there are two and three beats to a bar, are known as simple time. The division of each of the component beats into three produces compound time:

More complex times, such as the quintuple, $\frac{5}{4}$, usually fall into groups of 3 + 2, as in "Mars" from Gustav Holst's suite *The Planets*, and the second movement of Tchaikovsky's Sixth Symphony. Rimski-Korsakov, in *Sadko*, and Stravinsky, in *Le Sacre du Printemps*, use 11 as a unit. Ravel's piano trio opens with a signature of $\frac{8}{8}$ with the internal organization $\frac{3+2+3}{8}$. Folk song and folk dance, particularly from eastern Europe, influenced composers in the use of asymmetrical time-measures, as in the "Bulgarian Rhythm" pieces in $\frac{7}{8}$ and $\frac{5}{8}$ in Bartok's *Mikrokosmos*.

Period.—The time-measures, or bars, of music are part of a larger design known as a "period." The period most commonly found in classical music is of four bars, as in Beethoven's E major sonata, Op. 109, where the theme of the last movement has four phrases of four bars each. (*See* also Ex. 4, from Mozart's *Jupiter* Symphony.) Periods of three or six bars, though found in the songs of the troubadours and trouvères, are less frequent in later European music. Five-bar periods are still rarer, though Brahms uses a five-bar theme (*see* Ex. 2) and certain of Henry Purcell's grounds, *e.g.*, the Chaconne in G Minor, are based on a five-bar period. Some 20th-century composers use a recurrent cycle of bars of different time-signatures.

Influence of Body Movements.—The instinct for stress accent in music is closely associated with the natural behaviour of the body; thus for example, the rhythms of music have been much influenced (through folk music) by occupational movements such as hauling on a rope or rocking a cradle, which are reflected as strong stress accents (*see* also FOLK MUSIC: *Melodic and Rhythmic Patterns of Folk Songs*). In music as an art the influence of the dance has been paramount, and for this reason the types of musical instrument traditionally associated with the dance, *i.e.*, the drum and other percussion instruments (*q.v.*), have had an important place in music in most parts of the world. In Europe the cultivation of musical dance-forms during the Renaissance has left an important heritage, from the keyboard music of the 16th century to the suites of J. S. Bach. (*See* DANCE FORMS IN MUSIC.) Perhaps the most popular and influential dance of all has been the minuet, which originated as a French rustic dance; numerous examples are to be found in classical music. In Ex. 3, from the first minuet of Bach's orchestral Suite No. 1, the stresses are very clear.

Ex. 3 **J.S.Bach, Minuet 1, from Orchestral Suite No.1**

Accent by Note-Values.—Just as the pulse of music can be periodically accented by stress ("qualitative accent"), so can it be accented by duration of the notes actually sounded ("quantitative accent"). The note-values in modern use normally range from the semibreve (whole note) through the minim (half note), crotchet (quarter note), and quaver (eighth note) to the semiquaver (sixteenth note), and even the demisemiquaver (thirty-second note). (*See* MUSICAL NOTATION.) Several or all of these values may be found within a single piece, as in Ex. 4, the first eight bars of the finale of Mozart's *Jupiter* Symphony.

Ex. 4 **Mozart, Finale from the *Jupiter Symphony***

Influence of Language.—The arts of language, especially poetry, have always had an important part, through vocal music, in determining note-values. In language the units of duration are the long and short vowels, whose quantities are taken to be: one long = two shorts. Consequently their musical equivalents are: long = ♩ and short = ♪ (or respectively 𝅗𝅥 and ♩, or any other similar relationship of note-values).

Metre.—The combinations of long (–) and short (∪) syllables are known in prosody as feet. The system of notating the musical equivalents of feet derives from the application of prosody to music. For European music the foundations were laid in ancient Greece, where classical music and poetry were regarded as parts of a single art (*see* GREEK MUSIC [ANCIENT]). These principles were taken over by the Romans and were transmitted, by way of Latin poetry, to medieval Europe. The feet of classical poetry, and their equivalents in music, include:

	Poetry		Music	Groups of beats	Equivalent time-measures
duple	dactyl	– ∪ ∪	♩ ♫	2 + 2	$\frac{2}{4}$
	anapest	∪ ∪ –	♫ ♩	2 + 2	$\frac{2}{4}$
triple	trochee	– ∪	♩ ♪	2 + 1	$\frac{3}{8}$
	iamb	∪ –	♪ ♩	1 + 2	$\frac{3}{8}$
quintuple	cretic	– ∪ –	♩ ♪ ♩	3 + 2	$\frac{5}{8}$

and in late antiquity St. Augustine (354–430), in *De Musica*, added more.

Until the 12th century church music was virtually limited to unadorned plainsong (*q.v.*). The early polyphonic composers found that polyphony required a rhythmical organization to keep the parts together, and for this purpose rhythmic modes (*q.v.*) were adopted. These were classified as follows:

I	– ∪	(trochee)	♩ ♪
II	∪ –	(iamb)	♪ ♩
III	– ∪ ∪	(dactyl)	♩. ♪ ♩
IV	∪ ∪ –	(anapest)	♪ ♩ ♩.
V	– –	(spondee)	♩. ♩.
VI	∪ ∪ ∪	(tribrach)	♫ ♫

These metres were all considered to be in triple time, though No. IV is rarely found in music, and No. V and VI, having no differentiation in note-values, are not metres at all in a musical sense (but *see* METRE). Duple metres were also in use, as in two 13th-century French motets from the Montpellier Codex, where the notation indicates a note-grouping corresponding to the dactyl in duple time, *i.e.*, – ∪ ∪ interpreted as ♩ ♫ .

Compared with a hypothetical flow of beats equal in stress, metre adds significance to what was merely a forward flow in time—though the continuation of a metrical pattern may itself become monotonous. Thus metre, though "rhythmic" by comparison with pulse, is not the whole of rhythm. The 13th-century musicians often varied the rhythmic modes by combining several of them simultaneously in different parts of polyphonic composition.

Theoretically, metre appears to be without stress accent, and certainly much polyphonic music of a later period, such as the

Masses of Palestrina, has an almost stressless flow. Yet despite the absence of strong and weak accents the rhythmical organization of these works is very subtle. At a later period metre and time-measure cannot be wholly separated. In their "purest" forms they may be extremes, but in music predominantly of one type, the other element is rarely wholly absent, though on an instrument such as the organ actual dynamic stress is impossible. After all, metres like the spondee ♩♩, and the dispondee, ♩♩♩♩, need an accent on the first beat to keep their identity. Notwithstanding the opposite tendencies of metrical organization and stress accent, however, some metre is very obviously subject to stress, so that metre and time-measure become very closely linked, as in the scherzo of Beethoven's Ninth Symphony, where a bar has a strong first beat, while at the same time following a metre.

The organizing influence of language has sometimes led to combinations of different metres in the same melodic line; *e.g.*, the duet "Fear no danger to ensue," from Purcell's *Dido and Aeneas*, combines in alternation iamb and trochee (Ex. 5).

Ex. 5 Purcell, Duet from *Dido and Aeneas*

Phrase.—Tempo, time-measure, and metre may be regarded as the essential means of assessing music's flow in time. These form, so to say, the straight line of time. But rhythm needs also the "curves" of time. Curves are achieved not only by the use of rubato, cross-accent, and other means, but also by the use of the phrase. Phrases may coincide with periods, but more often go across them, to create an organic structure. The first eight-bar period (or first two four-bar periods) of the first stanza of the song quoted in Ex. 5, for instance, comprises 24 beats divided into a group of 11 beats followed by a group of 13 beats. These groups are called phrases, and the second phrase is further subdivided into 6 and 7 beats. Though the ultimate groupings of the melody refer to the mathematical framework of periods, they do not exactly correspond with these. In the example this is because of the need to convey the shape and sense of the words; for one feature of phrase is really the observance of "breath," whether this breath be actually taken or not. In vocal music, this often means shortening the last word—and therefore the last note—of a phrase, and taking an actual breath, as at a comma or semicolon in speech. But asymmetrical phrases are not confined to vocal music, and instrumental music often displays much ingenuity in the asymmetrical use of phrase. Phrasing, however, may be entirely symmetrical, and sometimes, especially in very simple music such as a hymn tune or a folk dance, it may correspond exactly to the framework of the period.

In broad terms, the mathematical framework of music, *i.e.*, its time, is comprised of tempo, time-measure, metre, and period; and its rhythmical life hangs on rubato, musical motif (which may already include cross-accent), and metrical variation, as well as on asymmetry and balance of phrase. Whereas the former are more or less mechanical factors, measured and rational, the latter are organically inspired and, numerically speaking, irrational—the very life of the music itself.

Prose Rhythms and Plainsong.—Rhythm is, therefore, not any one of these rational or formal features, nor is it comprised solely of a combination of these factors. Yet rhythm requires the background of a rational framework in order that it may be fully perceived. But this framework need not embrace all the rational factors described above. Thus plainsong, as it is known in modern times, makes no use at all of measure or of regular metre, yet it is, at the same time, supremely rhythmical in conception; its "free" rhythms are felt, as it were, not as rhythms of the body but of the soul. Whereas so much music has for its framework a regular repetition of underlying accent, whether stress or durational, the framework of plainsong is irregular (non-metrical). While omitting metre, it has developed other factors in greater degree. Its rhythm belongs to the Latin tongue and springs from the correct accentuation of each word in the Latin text and the dynamic quality already inherent in the grouping of the words. The opening phrase of the tonus simplex for the *Te Deum* (Ex. 6) illustrates these qualities.

Ex. 6 Plainsong: Tonus simplex for the Te Deum

Relationship of Rhythm and Melody.—Although, so far, music's structure in time has been examined separately from its structure in tone, no such separation is really possible. Melody and rhythm are intimately connected in the rhythmitonal structure of music. In Ex. 1, for instance, in which the music pursues a steady equal beat varied only by rubato and by the natural phrases and breaths arising from the words, it will be noticed that, whereas the melody usually moves from note to note conjunctly, the first note of each phrase takes an appreciable leap away from the last note of the previous phrase. This feature is so marked that it becomes a rhythmical factor, because of its periodic and time-organizing impression on consciousness. It is, in fact, accent by tone (or "tonal accent")—the equivalent of the "tonic accent" (*i.e.*, the principal stress in each word) in poetry. Moreover, various styles of music tend to standardize their melodic cadences, and, with them, their time-divisions. Thus, a typical cadence of plainsong prolongs the value of the penultimate note (as in Ex. 6).

Relationship of Rhythm and Harmony.—In music employing harmony the rhythmic structure is inseparable from harmonic considerations. The time-pattern controlling the change of harmonies is called harmonic rhythm. In 17th- and 18th-century music harmony tends to limit rhythmic subtleties and flexibility of the melodic elements (as well as determining the basic type of melody), at least in regard to stress accents. It is, therefore, no accident that the polyphonic music of Indonesia and southeast Asia, like much European music, exhibits certain four-square melodic tendencies. By contrast, the music of India and the Perso-Arab world employs a melody-instrument or voice performing in a given metre which a drum offsets by playing cross-rhythms, or (in the Arab world) by playing a quite different metre; and with no harmony (a drone excepted) to impede its flow, the rhythm can reach great subtlety and complexity.

Rhythmitonal Structure and Style.—In European music the great variety of styles derives from different concepts of rhythm in its relation to melody. They include the strict rhythmic modes of the 13th century; the free oratorical speech-rhythms of the Renaissance; the almost stressless flow of Renaissance polyphony; the strong body rhythms of the Baroque Period; the rhapsodic freedom of the late Romantics; and the primitivistic rhythms of 20th-century composers, with their composite and ever-changing time-signatures. The mathematically conceived rhythms of the serialist, or note-row, composers (Schoenberg and his followers) often seem to lack the organic quality of true rhythm.

Thus, a study of musical history shows a varying attitude toward rhythm. Sometimes it is closer to strict rule, sometimes to "freedom," according to the temper of the times and to the relative influence of poetry, dance, and folk music. Plato's definition of rhythm as "an order of movement," therefore, might be expanded. As a determining factor in the vitality of music, rhythm may be

described as "an inspired, organic order of movement," communicating intelligibly to the senses. Regarded from the analytical viewpoint, it operates within the rational framework already described, which it varies in terms of rubato, motif, and phrase. Ultimately, rhythm is the organic process of music in time; it is music's direction in time. The quality of rhythm is the quality of life itself, and however vitally the composer may conceive his music, he is ultimately dependent upon the performer to recreate it rhythmically in the act of performance (*see* EXPRESSION, MUSICAL).

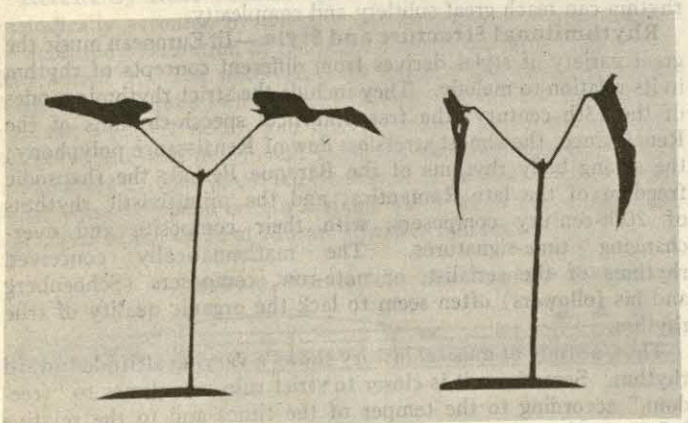
(P. C.-Ho.)

RHYTHMS, BIOLOGICAL, deep-seated rhythmic patterns of activity, exhibited by living things widely, and perhaps universally, the cycles of which are related to all the major natural geophysical periods. These rhythms, which appear to persist indefinitely—even in organisms shielded from fluctuations in all ordinary environmental factors such as light, temperature, humidity, pressure, and chemical changes—are considered to be a result of the continuous operation of a "biological clock" system.

PERIODS OF CYCLES

Daily Rhythms.—The activities of many animals and plants take place during periods of natural light, which follow a solar-day rhythm. Animals such as mice, cockroaches, and moths are active chiefly during the night; most songbirds and butterflies are active only during daylight hours. Many plants, including bean seedlings, show a daily sleep rhythm, their leaves drooping at night and becoming elevated by day; other plants display a comparable rhythmic closing of their blossoms at night. Man himself has a daily rhythm of sleep and wakefulness. All such daily changes as these simply reflect, and depend upon, innumerable interrelated supporting physical and chemical transformations within the individual organism. In the case of man, as an example, the daily alternation of sleep and wakefulness is accompanied by many substantial correlated changes, including activities of nervous and endocrine systems, and liver and kidneys. Daily variations occur in body temperature, and in pressure and composition of the blood. Such rhythmically recurring phenomena are each set to occur at the most effective time of day for the organism. Hence, concurrent 24-hour rhythmic fluctuations, set to various times of day, have been reported for numerous kinds of physiological changes in one and the same organism.

Another major environmental period involves the regular ebb and flow of the ocean tides, a cycle that subjects seashore plants and animals to a rhythmic change with typically two high and two low tides, occurring each lunar day of about 24 hours and 50 minutes duration. The ocean tides are effected chiefly by the gravitational rhythm caused by the earth's rotation relative to the moon. Some intertidal organisms such as barnacles, snails, clams, and oysters are most active when submerged by the rising tide. Others, like shorebirds and fiddler crabs, are specially adapted to feed on beaches exposed at ebb tide. Like solar-day rhythmic changes, these lunar tidal activity patterns are dependent upon numerous underlying and supporting physiological changes.



ADAPTED FROM W. ZIMMERMANN IN "TÜBINGEN NATURWISSENSCHAFTLICHE ABHANDLUNGEN"

FIG. 1.—BEAN SEEDLING LEAVES IN (LEFT) DAY AND (RIGHT) NIGHT POSITIONS, ILLUSTRATING A LIGHT-INFLUENCED CIRCADIAN RHYTHM

Although the ocean tides are effected chiefly by the moon, the gravitational attraction of the sun also has an influence. The sun and moon "cooperate" at new and full moons to produce the highest tides of each month, the so-called spring tides. At the moon's quarters the moon and the sun maximally oppose one another to produce the lowest high tides, or neap tides.

An interesting expression of solar and lunar rhythmicities in such animals as birds, insects, fishes, turtles, and crustaceans is evident in their sun-compass or moon-compass navigation. These animals can use the azimuthal angle of the sun or moon as a directional guide. This requires that the animals rhythmically alter their orientational angle at rates adjusted to compensate exactly for the earth's rotation relative to the sun and the moon.

An additional daily period suggested to occur in a living system is the sidereal day, of about 23 hours, 56 minutes. This is the period of the earth's rotation using stars as the reference. An explanation of bird navigation employing the stars as a compass requires that the angle of orientation of the bird gradually change with a sidereal-day period. Metabolic rate of potato plants is reported to have a sidereal-day rhythm, along with the other rhythms.

Monthly Rhythms.—The period from one new moon to the next, the synodic month, averaging 29.5 days, is the consequence of "beats" produced by periodic interference between the two closely similar rhythmic periods, the solar day and the lunar day. Among the biological activities linked to the synodic month are the reproductive cycles of some marine animals and certain plants and the human menstrual cycle. Monthly reproductive rhythms occur in the palolo worms of the Southwest Pacific, the fireworms of Bermuda, the grunion of the California coast, and a brown alga, *Dictyota*. These breeding rhythms are sufficiently precise in their relation to moon phase to enable one to predict quite accurately the times of the reproductive activity. The changing relations of the solar-day and lunar-day physical rhythms appear to time these breeding cycles, since the phase of the moon at which, for example, *Dictyota* breeds is related to the times of occurrence within the lunar day of the local high tides. The times, of course, differ from place to place.

Although little is known about the timing of the human menstrual cycle or the approximately semimonthly estrus cycles of such animals as sheep and pigs, two fundamentally different hypotheses have been offered for the timing of these cycles. One is that they are timed by fully independent periodic oscillations; the other is that the cycles are dependent for their timing on periodic interference between 24-hour and circalunadian (about a lunar day) cycles.

Yearly Rhythms.—Another major rhythmic period for living things is the year. In most parts of the world substantial seasonal changes in light and temperature are correlated with rhythmic biological phenomena predominantly related to activity, reproduction, and growth. For example, in higher plants in the northern hemisphere, growth, flowering, and seed production typically occur during the warmer months. In the oceans there are conspicuous rhythms in abundance of planktonic organisms. Also evident among many animals are annual reproductive rhythms, correlated with physiological, morphological, and behavioural changes, and extensive migrations to and from breeding grounds.

Longer Cycles.—Cycles of abundance in a variety of species in nature with periods of several years have been described. These include three- to four-year cycles of abundance of lemmings and the approximately ten-year cycles of Canadian lynx, varying hare and ruffed grouse.

Cyclic changes in growth rate, displaying several period lengths of a number of years each, have been noted from studies on tree rings. These long-period cyclic variations are still controversial as to their genuinely rhythmic character and their exact period lengths.

PERSISTENCE OF CYCLES

Endogenous Rhythms.—The French astronomer J. J. D. de Mairan (1729), who observed plant sleep rhythms, was the first to report that these rhythms were somehow independent of the daily changes in environmental light. This persistence of the leaf rhythm in unvarying light and temperature was studied extensively about the turn of the century by Wilhelm Pfeffer. Since Pfeffer's time, numerous investigators have discovered comparable persistence of daily rhythmic patterns in a wide variety of animals and plants, establishing the concept of endogenous, or inherent, rhythms.

BY COURTESY OF FRANK A. BROWN, JR.

FIG. 2.—FIDDLER CRABS IN NIGHT (PALE) AND DAY (DARK) STATES

The colour change rhythm of one of the crabs has been reset 12 hours by a few days of inverted light cycles

Likewise, other investigators, studying marine intertidal organisms, noted that such organisms continue to exhibit tidal rhythms when moved to the laboratory, far from immediate tidal changes. Such persistence of lunar-tidal rhythms in marine organisms has since been confirmed for a wide variety of species ranging from diatoms and protozoans to fishes. The most extensive studies have concerned the rhythms of activity and feeding of bivalve mollusks and crabs.

Annual rhythms have been demonstrated to occur in the absence of all known environmental cues. Seeds display an annual rhythm in their rate of germination under carefully controlled constancy of all factors known to influence them. Potato plants, carrot slices, and freshly germinated bean seedlings hermetically sealed under conditions of constant light, temperature, humidity, and pressure have a higher metabolic rate in spring and early summer than in fall.

Clearly, living organisms even when fully shielded from all natural rhythmic forces to which they are known to react still have "biological clocks" for maintaining rhythmic changes closely similar in their period lengths to the natural environmental cycles.

The timing mechanism for these "clocks" possesses some extraordinary properties. The period lengths of the persisting daily cycles are influenced relatively little by temperature changes that accelerate or depress greatly the rate of all ordinary metabolic processes within the body, or by most chemical substances. The persistent solar-day rhythm of colour change in fiddler crabs shows no change in its cycle length over a temperature range of about 20° C; the period of the lunar-tidal rhythm in activity is also unaffected by temperature. Dried seeds display an accurate annual rhythm in germination whether stored at −22° C or +45° C.

Resetting of Rhythmic Events.—Such daily rhythmic events as running activity in mice or cockroaches, skin darkening in fiddler crabs, bioluminescence in dinoflagellates, and sleep or wakefulness in man are adaptively set to occur at particular clock hours of the day. When man or other organisms are transported rapidly to a different time belt of the earth, they arrive with their rhythmic changes still set to the time of their former abode. But subjection for a few days to the physical cycles of the new time belt results in gradual resetting of the biological rhythms until they come to bear a relation to the new local time fully comparable to that of their former location. That the local light and temperature changes normally play important roles in this resetting activity is evident from the fact that without any geographical displacement whatsoever, one can reset such organismic daily rhythms to accord with light cycles of any given time belt simply by experimentally subjecting the organism to a few 24-hour cycles of light or temperature changes as they would occur in any particular time belt.

Similarly, the lunar-tidal rhythmic events of such creatures as mussels, oysters, and crabs normally correspond with the times of the tidal changes on a particular beach. Mussels transported to another beach gradually alter their time of activity over the course of a few days to accord with the new tidal schedule. Oysters and crabs removed from their beaches to tideless laboratory containers gradually reset the time of their activities to synchronize with upper and lower transits of the moon; *i.e.*, with the times of high lunar tides of the atmosphere. The normal setting factors for the tidal rhythms are not known.

Components of Rhythms.—The daily rhythmic changes of organisms possess two kinds of components: phase-labile and phase-stable. One of these, the phase-labile, like the majority of the examples described earlier, is capable of having the pattern of events in each cycle shifted or reset by artificial light or temperature cycles to any desired relationship to the clock hours of the day. The phase-stable rhythms are of extrinsic origin, a consequence of continuous biological response to fluctuations in subtle geophysical forces. Evidence for such origin comes from continuing correlation between day-to-day irregularities and distortions in these daily variations and the concurrent, unpredictable irregularities in the daily tides of the atmosphere, measurable as barometric pressure changes, or other rhythmic physical forces such as atmospheric temperature and high-energy radiation. Pressure and temperature are not themselves the direct agents of daily rhythms, since, as mentioned earlier, these correlations persist in organisms completely shielded from variations in the environment.

Along with the phase-labile, adaptive tidal rhythms of behaviour of marine organisms, there are also phase-stable lunar-day fluctuations of extrinsic origin. Evidence for their extrinsic nature is of two kinds. One is the strikingly parallel patterns of the lunar-day fluctuation in organisms as diverse as potatoes, seaweed, carrots, earthworms, salamanders, and mice. The other is the tendency, mentioned earlier, of oysters and crabs taken from their beaches to assume a new common setting related to the lunar atmospheric tides.

An annual organismic rhythm that persists in constant light, temperature, and pressure seems also of extrinsic origin. The day-to-day organismic correlations with solar tides of the atmosphere continue through the year, reflecting the annual variation in these tides. Such extrinsically derived annual variations are distinguished from such phase-labile annual biological rhythms as that of flowering of plants and of bird migration and reproduction, whose times of occurrence in the year may be reset to an earlier or later time by subjection to experimentally lengthened or shortened light periods. Such response to photoperiodism (*q.v.*) appears to play a "setting" role for phase-labile annual rhythms comparable to that of light onset and termination for phase-labile daily cycles. It appears probable that the daily rhythm normally serves the organism as the reference to enable it to measure accurately the lengths of the light and dark periods.

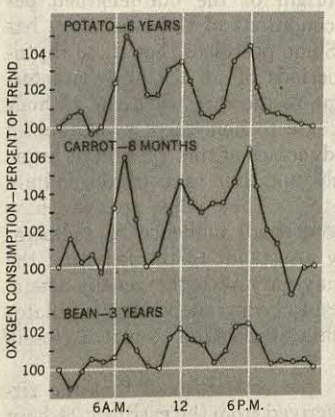


FIG. 3.—MEAN DAILY FLUCTUATION OF METABOLIC RATE OF POTATOES, CARROTS, AND BEAN SEEDS HELD IN CONSTANT LIGHT AND TEMPERATURE

The rhythmic geophysical forces responsible for extrinsic biological rhythmicity have not been identified. Recent demonstrations of extraordinary organismic sensitivities to very weak magnetic, electrostatic, and electromagnetic, including gamma-ray, fields have provided theoretically possible means of regulating certain cycles.

Rhythms in Unvarying Light and Temperature.—Both the phase-stable and phase-labile daily rhythmic changes continue with an accurate aver-

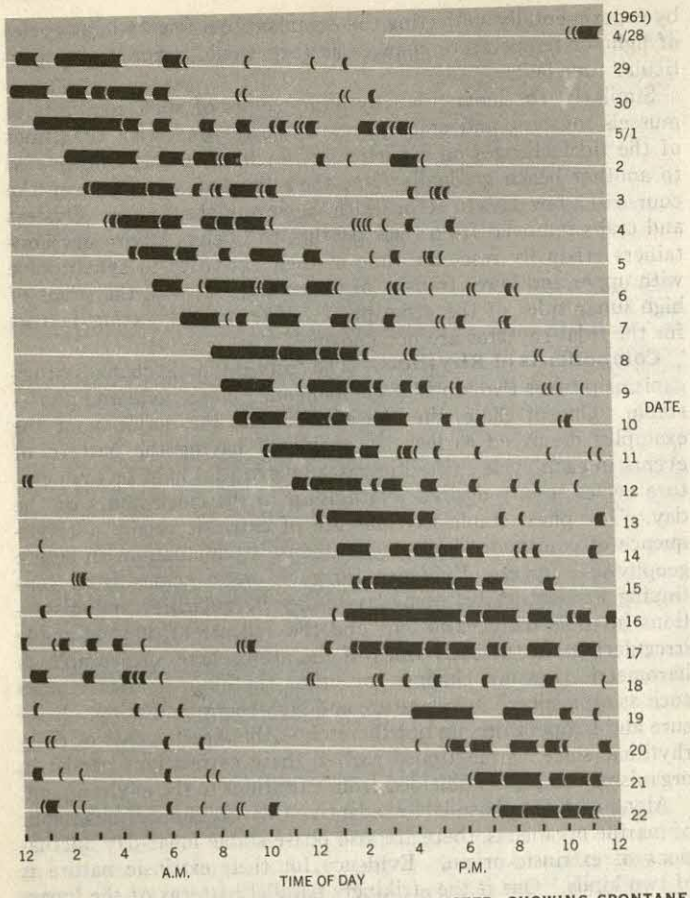

FIG. 4.—TYPICAL CIRCADIAN RHYTHM OF A HAMSTER, SHOWING SPONTANEOUS DAILY ACTIVITY PATTERNS

age 24-hour period as long as the organism is exposed to natural day-night changes at the same longitude. When, however, organisms are held in artificially maintained constant levels of illumination and temperature, the phase-labile rhythmic complex very commonly drifts steadily toward earlier or later hours of the day.

Consequently, rhythmic periods either shorter or longer than 24 hours are observable. The length of these latter cycles may usually be increased or decreased by changing the level of the constant illumination or temperature. These rhythms that deviate slightly from a 24-hour period have been termed circadian (about a day). Their period seldom exceeds 20 to 28 hours. The extrinsic component always retains an accurate average 24-hour period under these conditions of unvarying light and temperature.

THEORIES REGARDING RHYTHMS

Natural Oscillation.—The origin of the odd-lengthed periods observed in the controlled conditions of the laboratory has long been a controversial issue. Some postulate that these rhythmic fluctuations reflect natural periods of oscillation, characteristic of each organism, which come to the fore when the 24-hour cycles of light and temperature cease to hold them synchronized with the local day-night cycle. Advocates of this hypothesis argue that external physical cycles could not time each of the infinite variety of observed period lengths. They point to the phase lability, and a commonly observed small influence of temperature level on cycle length. They also point to the fact that the length of the circadian periods may vary with the genetic strain. In brief, the organism is postulated to be an independent oscillator whose periods have evolved by natural selection to match closely the period of the solar day.

Extrinsic Influence.—Others postulate instead that the circadian rhythms are continuously derived from the extrinsic 24-hour variations which thus serve as a temporal frame of reference. The organism is presumed to be a variable frequency transformer, depending upon the steady 24-hour rhythmic input to derive the circadian periods through operation of the same rhythm-resetting machinery that normally adjusts the phase-labile daily patterns to a different time belt. Organisms normally employ phase-labile daily rhythms of sensitivity to light and temperature in resetting their rhythmic patterns. During a sensitive part of each daily cycle increased light or temperature will reset the cycle either backward or forward; for the remainder of the cycle relative insensitivity prevails. Under natural conditions the sensitive period becomes and remains set to fall at night.

In unchanging light and temperature the organisms' daily rhythm of sensitivity is postulated to present an illusion that the environmental light and temperature are varying, with times of day of the "illusory light changes" resembling the natural experience of organisms abruptly displaced halfway around the earth. This would be expected to activate resetting of the phase-labile sensitivity rhythm and all other associated phase-labile rhythms. Such daily resetting, termed autophasing, would be expected to continue indefinitely generating a circadian period slightly longer or shorter than 24 hours, depending on the direction of resetting. With this hypothesis the small influences of temperature and light levels and of genetic constitution on cycle length are readily interpreted, and the extraordinary drug and temperature independence of the rhythm period finds a simple, plausible explanation. This postulated dependence of the circadian rhythms upon extrinsic timing brings them into a common general explanation along with persistent lunar-day, monthly, and annual rhythms.

It has not yet been possible to design a crucial experiment to learn which of the two foregoing hypotheses of persistent rhythms is the correct one. It is possible that both kinds of mechanisms exist simultaneously in organisms.

RIBATEJO, a province of central Portugal, lying astride the Tagus Valley. It was formed in 1933 and is bounded west by Estremadura and east by Beira Baixa and Alto Alentejo. Area 2,807 sq.mi. (7,270 sq.km.). Pop. (1960) 478,261. There are three marked relief zones. In the west the detrital hills border the Upper Jurassic and Tertiary massifs from Alcanena (and Alenquer in Estremadura) to Vila Nova da Rainha. East of this zone and north of the Tagus are extensive rolling plateaus, less developed south of the Tagus except to the east and northeast of the Sierra de Almeirim. The third zone includes the three Quaternary terraces and the alluvial plain of the Tagus, forming a broad lowland, especially south of the river. The northern border of Ribatejo coincides neatly with the edge of the Tertiary depression and the Mesozoic limestone hills of Estremadura. To the south, the region merges almost imperceptibly into Alentejo.

On the north side of the Tagus, land use is diverse. Vineyards, olives, and cereals are found on the hill lands, and many districts (*e.g.*, Cartaxo and Torres) are famous for their wine. Along the Tagus Valley, maize (corn) and vines on the light soils, rice and wheat on the heavy lands, and wet meadows for the rearing of bulls and horses, provide a variety of intensive agriculture. South of the Tagus the landscape is less tamed; much is still unproductive or in extensive estates of cork forest. This contrast explains the density of population: 75 per sq.mi. on the north side, under 25 per sq.mi. on the south.

Along the Tagus are the chief towns: Santarém (17,276), the capital; Almeirim (8,815); and Vila Franca de Xira (14,633). An important centre in the north is the historic town of Tomar (15,118).
(J. M. Ho.)

RIBBENTROP, JOACHIM VON (1893–1946), German statesman, minister for foreign affairs (1938–45) in the Nazi government, was born at Wesel on April 30, 1893, the son of an army

officer. Educated at Kassel and Metz, then in Grenoble and in London, he went to Canada in 1910 as a commercial representative. Returning to Germany in 1914 he served in World War I in a Hussar regiment on the eastern front but in 1915 was attached to the German Military Mission in Turkey.

After the war he entered the wine trade and married Anna Elisabeth, the daughter of a manufacturer of sparkling wine, Otto Henkell. Having been adopted by a distant relative whose father had been knighted in 1884, he styled himself "von Ribbentrop."

On Aug. 13, 1932, at Berchtesgaden, he met Hitler for the first time and joined the National Socialist Party in the same year. As German chancellor, Hitler made Ribbentrop his chief adviser on foreign affairs and put him in charge of the so-called *Dienstelle Ribbentrop,* housed in the Wilhelmstrasse opposite the Foreign Office, to which it became a rival and duplicate organization. Having been appointed special commissioner for disarmament in 1934, Ribbentrop toured foreign capitals to prepare the way for German rearmament. As ambassador-at-large he negotiated the Anglo-German Naval Agreement of June 18, 1935. In August 1936 he was appointed ambassador to Great Britain. He had hoped to use his tenure of the embassy to develop a close Anglo-German understanding, along the lines envisaged by Hitler in *Mein Kampf;* but he failed to do so and found himself treated as a tactless parvenu. His attitude toward Britain changed as a result, and when, on Feb. 4, 1938, Hitler appointed him his minister for foreign affairs he was a convinced Anglophobe. Although he thought conflict with Britain to be inevitable in the long run, he assured his master in 1939 that he need not fear any effective British support for Poland.

He signed in Moscow the German-Soviet nonaggression agreement of Aug. 23, 1939, which contained a secret annex describing how Poland would eventually be partitioned, and he returned there to sign a second German-Soviet treaty (Sept. 28, 1939) readjusting that partition. Thereafter his importance declined.

Ribbentrop was a vain man, impressed with his own importance, always subservient to Hitler. Although he was responsible for many important acts of German foreign policy, he did not make policy, was lacking in judgment, and showed no skill as a negotiator. He made himself neither respected nor feared and survived only through the support of Hitler. He was further discredited by the complicity of some of the Foreign Office staff in the assassination plot of July 20, 1944. In April 1945 he disappeared from Berlin but on June 14 was found and arrested by the British in Hamburg. Indicted as a war criminal at the Nürnberg war crimes trial he was found guilty on four principal counts and sentenced to death. He was hanged at Nürnberg Prison on Oct. 16, 1946.

In prison he wrote his memoirs entitled *Zwischen London und Moskau,* published by his widow in 1953 (English translation, *The Ribbentrop Memoirs,* 1954).

See P. Schwarz, *This Man Ribbentrop: His Life and Times* (1943).

(W. Kp.)

RIBBLE, a river in Yorkshire and Lancashire, Eng., is formed by the confluence of the Gayle and Cam becks, which rise in limestone country on Langstrothdale Chase at heights of 1,650 and 1,850 ft. (503 and 564 m.). The river first flows almost due south between Ingleborough (2,373 ft. [723 m.]) and Pen-y-ghent (2,273 ft. [693 m.]) and, after passing the villages of Horton-in-Ribblesdale and Stainforth, reaches Settle, a local centre with a 700-year-old market charter and Giggleswick School (founded 1512) ¾ mi. away. The Ribble then passes into open country and traverses the bed of a postglacial lake, originally 4 mi. (6 km.) in length, but now drained. The preglacial course of the river is believed to have been southeastward to the River Aire, but an extensive spread of morainic material and drumlins, left by the glaciations, blocked this route, and the river now turns southwestward through an attractive 8-mile gorge at the end of which, near Bolton-by-Bowland, it meets Tosside Beck, which may have been the original main river. From this point to Preston it flows in a wide valley, mostly devoted to pastoral farming but with numerous scattered trees, passing Clitheroe, Whalley, and Ribchester. Near Whalley it is joined by its two main tributaries, the Hodder, draining much of the Bowland Forest from the north, and the Calder, which switches from the Burnley Valley to the Ribble by a deep cut through the Pendle ridge. Thus augmented, the Ribble meanders between bluff lines, which rise 150 ft. (46 m.) high, a mile apart, on either side of the floodplain. They are largely composed of boulder clay. Preston (*q.v.*) lies on the northern side of the river at its lowest bridge point, where the Lancashire Plain is narrowed to a few miles by a westerly bulge of the Pennines and an easterly incursion of the Irish Sea, the Ribble Estuary. From Preston to the general line of the coast between Southport and Blackpool (*qq.v.*) is 12 mi. (19 km.), and most of this is infilled by extensive sandbanks and mud flats, many of which have been reclaimed by embanking for agricultural land. The shipping channel to the port of Preston makes its way through these banks and is the artificially straightened main channel of the Ribble. Its depth is maintained by dredging where necessary.

(R. K. Gr.)

RIBBON, a narrow woven fabric of varying widths made from rayon, acetate, silk, nylon, etc. It is used for trimming, military decorations, packaging, typewriter ribbon, and adornment. Some acetate and nylon ribbon has a seared rather than a woven edge.

Both single- and double-faced satin weaves are used for ribbon, the latter being lustrous on both sides. Faille, taffeta, and moire also are popular ribbon weaves. Lingerie ribbon, of which there are several types, is soft, smooth, and supported by strong, compact selvages that make it ideal for women's and children's undergarments. Grosgrain ribbon, especially popular for millinery, has a silk, acetate, or nylon warp and a cotton weft. Because of the rib construction the weft is not visible.

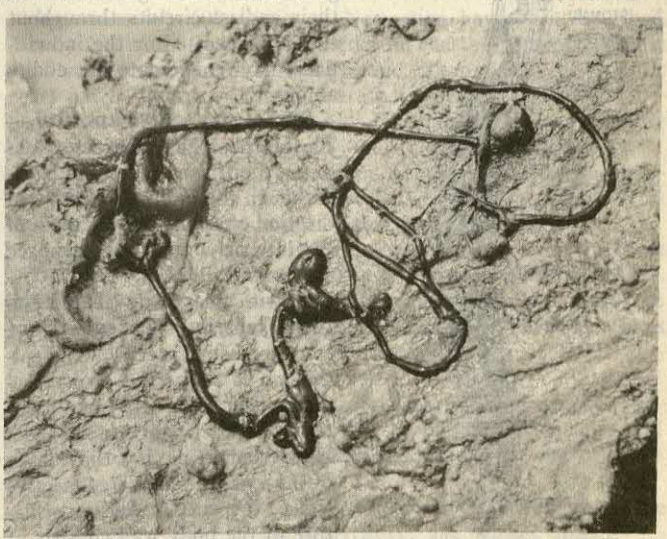
Typewriter ribbon is a plain weave of cotton or nylon and has the highest thread count of any fabric in general use—from 200 to 350 threads per inch.

(G. R. Co.)

RIBBON WORM, the common name for mostly aquatic invertebrate animals constituting the phylum Nemertina (Nemertea) and called also nemertines or nemerteans. All are characterized by a soft, highly extensible body, elongate and ciliated, and by a readily eversible proboscis, for which the group is sometimes called proboscis worms. "Nemertea" is from the Greek meaning "unerring" and refers to the accuracy with which the proboscis can be aimed at prey. Most species are found along seashores round the world but some are found in fresh water and on land. The blackish-brown bootlace worm (*Lineus longissimus;* fig. 1) of North Sea shores is a fragile nemertine that may reach a length of many feet, while the slender reddish *Prostoma rubrum,* of pools and streams in North America, is usually less than one inch long.

GENERAL FEATURES

Description.—Nemertines vary greatly in size and shape; some are long, flattened and ribbonlike, while others are short and threadlike; some are cylindrical, while others are broad and flat.



M. A. WILSON

FIG. 1.—A HETERONEMERTINE, THE BOOTLACE WORM (LINEUS LONGISSIMUS), ON A SPONGE-COVERED ROCK ON THE SEASHORE

In nearly all forms the body may be contracted to a small fraction of the length it has in full extension. In some species of nemertines the proboscis is coiled and is longer than the body.

Many of the species are brightly coloured in life, with shades of red, orange, yellow, green, gray and brown predominating. Some have a uniform coloration, others have definite patterns or markings of contrasting colours, with rings, longitudinal lines, spots or reticulations. The physical basis of the colour patterns consists of pigment granules secreted within the epithelial cells of the integument or in the underlying connective tissue cells or both.

All nemertines are carnivorous, feeding on protozoa, turbellarians and other worms, mollusks, crustaceans and the young of all the invertebrates with which they come in contact. Some have such distensible mouths that they can devour animals of almost their own diameter. Others have small mouths and suck in only the juices of their prey. When food is not obtainable the nemertine is able to live for a long time upon the nourishment to be obtained from its own tissues. Individuals of some species may thus survive starvation for a year or more. In the meantime the body may have shrunk to $\frac{1}{20}$ or less of its former size. Some of the small forms may survive unfavourable conditions by coiling their bodies in a firm cyst of secreted mucus, to resume activity at a later time.

Habitat and Distribution.—Most of the species are marine and littoral; many of them burrow in sand or mud; others hide beneath stones or creep about among algae and other growths between tide marks or in shallow water. The members of the tribe Pelagica are strictly bathypelagic, with flattened, gelatinous bodies adapted for floating idly or swimming sluggishly far beneath the surface of the deep oceans. A few species inhabit fresh-water streams and lakes; others have migrated to the land, living in moist earth or beneath fallen logs, stones or dead foliage. Certain species live as commensals in the mantle cavities of bivalve mollusks or of tunicates, in the canals of sponges or beneath actinian sea anemones; and finally several species are parasitic on the gills and among the egg masses of crabs.

Nemertines are found along all the seacoasts of the world and off the shores to depths of hundreds of metres. Some of the species are circumpolar, extending southward along the coasts as far as Madeira, southern New England, California and Japan. A few species live in both the northern and southern hemispheres. Some are limited to the polar seas and others to the tropics. Some of the bathypelagic species live at depths of 1,000–2,000 mi. or more and the population may be carried for thousands of miles by the deep ocean currents, reproducing generation after generation in their endless circuits throughout the great oceans, or the individuals may congregate in eddies among the currents.

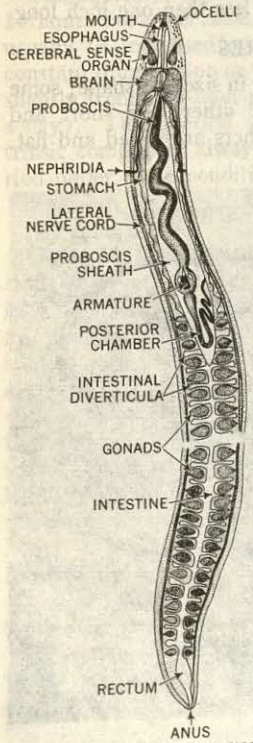


FIG. 2.—ORGAN SYSTEMS OF A HOPLONEMERTINE

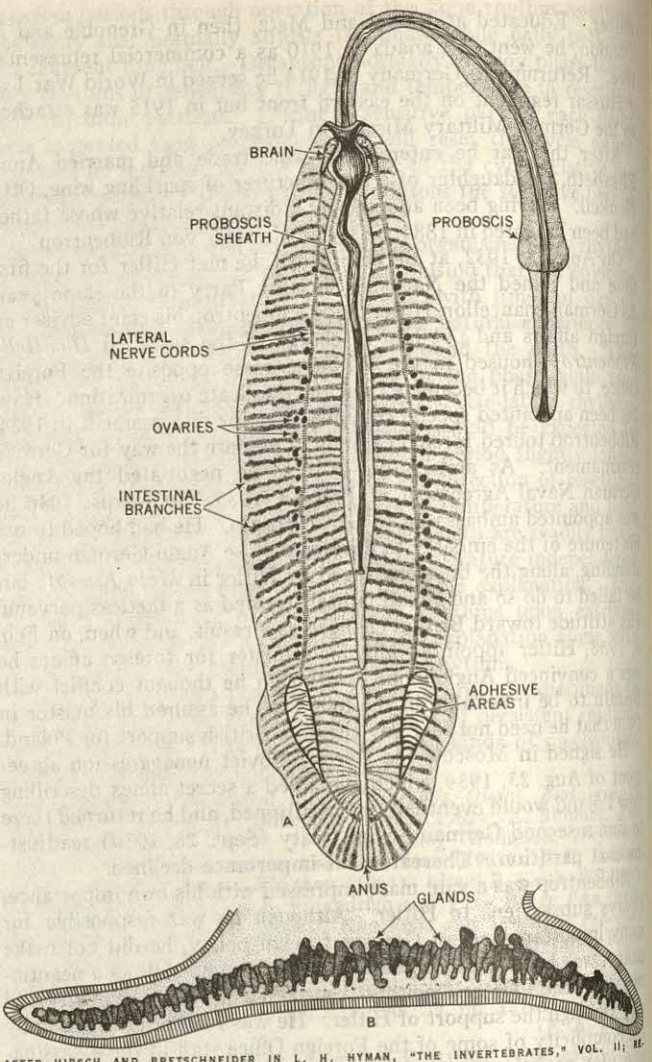
Structure and Function.—The morphological characteristics of a nemertine are shown in fig. 2. Although there is no external indication of segmentation, most of the internal organs are arranged metramerically. The body is covered with a layer of ciliated epithelial cells, interspersed with mucous and sensory cells. The epithelium is supported on a basement layer of firm gelatinous tissue, beneath which, in the order Heteronemertina, is a thick layer of mucous glands and connective tissue, the cutis. The musculature of the body wall consists of two or more layers of circular, spiral and longitudinal muscles that enable the worm to carry on rapid changes in body form. Locomotion is accomplished by creeping or gliding, by alternate elongation and contraction, by twisting spirally or, in a few species, by swimming. The proboscis is sometimes used as an aid in creeping or burrowing.



AFTER HIRSCH AND BRETSCHNEIDER IN L. H. HYMAN, "THE INVERTEBRATES," VOL. II; REPRODUCED BY PERMISSION OF MCGRAW-HILL BOOK CO., 1951

FIG. 3.—CROSS-SECTIONAL VIEWS OF: (A) PLOTONEMERTES, FEMALE; (B) ADHESIVE DISK SHOWING GLANDS OF MALACOBDELLA

Proboscis.—The proboscis is formed by an invagination of the anterior body wall and consequently has essentially the same muscular and epithelial layers but in reverse order. In its normal position within the body it lies within the proboscis sheath, which forms a closed, saclike cavity, the rhynchocoel, filled with a corpusculated fluid. In a few species of the order Hoplonemertina the sheath is provided with paired diverticula. The anterior end of the proboscis is anchored firmly into the tissues of the head near the brain, while the posterior end commonly terminates in a long retractor muscle attached to the proboscis sheath or in some species to the musculature of the body wall in addition. The proboscis is everted through the rhynchodeum by the combined action of its own muscles and such contractions of the musculatures both of the sheath and body walls as will exert pressure on the fluid in the rhynchocoel. It is withdrawn by reducing this pressure, aided by its own musculature and by the retractor muscle, if present. In the class Anopla the tenacious mucus and paralyzing secretions of the everted proboscis aid in capturing the prey, while in the class Enopla the stylet is also used. Most of the Enopla have two or more pouches of accessory stylets which may replace the central stylet if lost or broken. In the heteronemertine *Gorgonorhynchus* the proboscis is forked.

Digestive System.—The digestive system consists of an anterior mouth, which may open either ventrally posterior to the brain or

terminally in connection with the proboscis opening. In the order Bdellonemertina and some Hoplonemertina the mouth joins the rhynchodeum to form an atrium. The mouth leads to a slender esophagus and thence to a more spacious stomach. The intestine continues as a straight tube, usually with numerous paired lateral diverticula, from the stomach to the rectum, which opens at the posterior end of the body (fig. 2). Some forms have a large caecum, with caecal diverticula, which extends forward from the anterior end of the intestine, while in some of the order Paleonemertina and all of the Bdellonemertina there are no intestinal diverticula whatever (fig. 4). Digestion of the food materials is accomplished mainly by enzymes secreted into the stomach and intestine, although the fats are taken by phagocytosis directly into the cells of the lining epithelium. In these cells also the nutrients are stored in vacuoles until needed in the body metabolism.

FIG. 4.—ORGAN SYSTEMS OF A BDELLONEMERTINE

Circulatory System.—The circulatory system consists typically of three longitudinal blood vessels, united at both ends of the body, and in most species with reservoirs, or lacunae, in the head and esophageal region and with numerous cross branches throughout the body.

Excretory System.—The excretory system is highly diversified. Typically there is a pair of profusely branching nephridia in close proximity with the lateral blood vessels and having one or more pairs of efferent ducts leading to the exterior of the body (fig. 2). Each of the numerous minute branches originates from a multinucleate terminal organ (metanephridium) or from a single cell (protonephridium) with long flagella that draw fluid from the surrounding parenchyma into the nephridial canal. Other cells in the walls of the canals excrete metabolized waste products. In the terrestrial nemertines (*Geonemertes*) there are several thousand separate nephridia, each with its own efferent duct. Excretory organs have not been found in any of the bathypelagic species.

Nervous System.—The central nervous system consists of a four-lobed brain, from which a pair of large lateral nerve cords extend to the posterior end of the body. Many species have in addition a dorsomedian and a ventromedian nerve with branches communicating with the lateral nerve cords. Connected with the central nervous system are one or more pairs of proboscidial nerves and numerous, often paired, peripheral nerves associated with the muscular and digestive systems, integument, ocelli and such other sense organs as may be present.

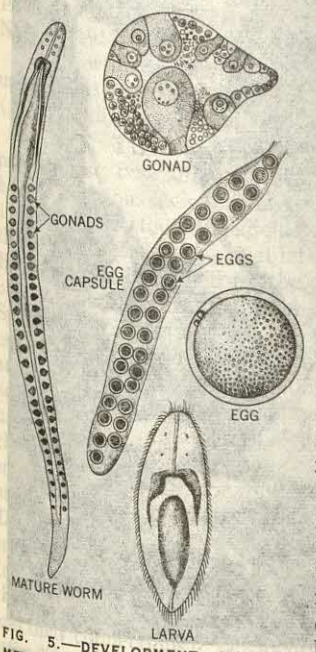


FIG. 5.—DEVELOPMENT WITHOUT METAMORPHOSIS IN A HOPLONEMERTINE (PROSTOMA RUBRUM)

Sense Organs.—In addition to the sensory epithelium everywhere present in the integument, some of the species have other specialized sense organs, including ocelli, cerebral, lateral and frontal sense organs, cephalic grooves and pits. In a single family (Ototyphlonemertidae) there is a pair of statocysts connected with the brain. With the exception of these organs of equilibrium and the ocelli very little experimental evidence has been obtained as to the precise nature of the sense organs. Chemical senses, including the recognition of food substances, positional sense, tactile sense and a certain degree of light sense must be located in the epithelium on all parts of the body, for headless fragments respond to the corresponding stimuli.

Life Cycle.—*Reproduction and Development.*—In most nemertines the sexes are separate, although a few species are hermaphroditic. The gonads are simple sacs which usually alternate with the intestinal diverticula and may therefore be very numerous (fig. 2 and 5). In most species the sexual cells from each gonad are discharged directly into the water. Fertilization is thus external except for the few cases of viviparity in which the development of the embryo takes place within the body of the parent. In a few of the bathypelagic nemertines the spermaries have been shifted to the head, and in the parasitic *Carcinonemertes* there is a common sperm duct that opens into the rectum.

Embryonic development may be direct, leading to the formation of a larva similar to the adult, or it may be indirect, with a free-swimming, hemispherical larva of complicated pattern known as the pilidium. The young worm later develops by metamorphosis within the pilidium. Increase in length occurs by constant additions to the posterior end of the body.

Modes of Living.—Young *Carcinonemertes* species are parasites on the gills of certain crabs; as one-inch-long reddish adults, these ribbon worms feed on the egg masses of crabs and live as commensals, preying on small animals that attach to their hosts. Many commensal ribbon worms live in tunicates, sponges and bivalves and share the food drawn in by their hosts.

Regeneration.—Enemies are numerous, particularly annelids, crustaceans and fishes. Contributing to survival, however, is the tendency of most individuals with long bodies to break in fragments whenever any part of the body is seized. If only the posterior portion of the body is lost the missing parts are soon restored by regeneration.

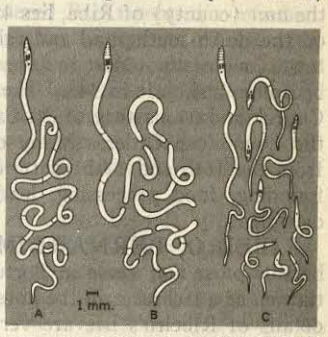

FIG. 6.—ASEXUAL REPRODUCTION BY FRAGMENTATION IN LINEUS SOCIALIS

In certain species any small fragment of the body, with or without the head, will regenerate into a minute worm of normal proportions (fig. 6). Fragmentation thus becomes a method of asexual propagation. Only a few species, however, have the capacity of restoring a missing head, but a lost or injured proboscis is promptly replaced.

CLASSIFICATION

Approximately 600 species of Nemertina have been described. Nearly 200 of these are found along the coasts of Europe, 150 on the Pacific coast of North America and Japan, 60 on the Atlantic coast of North America and 70 are bathypelagic, floating far beneath the surface of the oceans. The phylum is conveniently divided into two classes, each of which consists of two orders.

Class Anopla.—Mouth posterior to brain; central nervous system imbedded in body wall, either between the muscular layers or external thereto; and proboscis not armed with stylets.

Order Paleonemertina.—Body musculature of two or three layers; cutis absent. Example, *Procephalothrix, Tubulanus* (fig. 7).

Order Heteronemertina.—Body musculature of three layers, to which a thin inner circular and an outer spiral layer are sometimes added; cutis well developed. Examples, *Lineus* (fig. 1), *Cerebratulus.*

Class Enopla.—Mouth anterior to brain; central nervous system situated in parenchyma internal to body musculature; and proboscis (except in Bdellonemertina) armed with one or more calcareous stylets.

Order Hoplonemertina.—Proboscis with armature; intestine straight, with paired lateral diverticula; and sucker absent.

Suborder 1. Monostylifera, with single stylet on awl-shaped basis. Examples, *Amphiporus, Prostoma* (fig. 5).

Suborder 2. Polystylifera, with several stylets on curved basis.

Tribe 1. Reptantia, adapted for creeping or burrowing.

Tribe 2. Pelagica, adapted for swimming or floating in the ocean depths. Example, *Pelagonemertes.*

Order Bdellonemertina.—Proboscis without armature; intestine convoluted, slender, without diverticula; with sucker at posterior end of body; and commensal in the mantle cavity of marine bivalves. Example, *Malacobdella* (fig. 3).

RIBE, a town of southern Jutland, Denmark, and capital of the *amt* (county) of Ribe, lies 4 mi. (6 km.) from the west coast on the north-south road and railway. Pop. (1960) 7,809. The town (one of the oldest in Denmark and first mentioned in 862) became a bishopric in 948. The cathedral dates from 1117. The Church and Monastery of St. Catharine were founded in 1228 by the Dominican Order. Many of the half-timbered houses date from the 16th and 17th centuries. Local industries include iron founding, food processing, leather working, bulb growing, and dairying.

(Ro. H. T.)

RIBEIRO, BERNARDIM (*c.* 1482–1552), the father of bucolic prose and verse in Portugal, was a native of Torrão and the son of a treasurer in the household of the duke of Viseu. The details of Ribeiro's life are very uncertain. Between 1507 and 1512 he was a student in the faculty of law at the university, which was at that time in Lisbon. He later frequented the court of King Manuel where he won the friendship of the poet Sá de Miranda and perhaps fell in love with one of the court ladies, whose identity is unknown. In 1521 he probably went to Italy; it was there, perhaps, that he wrote his chivalric and pastoral romance, *Menina e Moça,* in which, it is thought, he may have related his own love story, personifying himself under the anagram of "Binmarder" and the lady under that of "Aonia."

On his return he was appointed secretary to King John III (1524). About 1540 he seems to have suffered some mental derangement and he died insane in Oct. 1552 in the hospital of Todos os Santos, Lisbon.

The *Menina e Moça* was first printed at Ferrara in 1554, together with six eclogues (including the eclogue *Crisfal* which may not be his) and some minor poems. A second edition appeared in Évora in 1557, containing a much longer version of the story but it is doubtful how much of this is Ribeiro's own work.

Modern editions are *Obras de Bernardim Ribeiro e Cristovam Falcão* by A. Braamcamp Freire, two volumes (1923); *Obras Completas de Bernardim Ribeiro* by A. Ribeiro and M. Braga, two volumes (1949–50); and *História de Menina e Moça* by D. E. Grockenberger (1947).

See A. Salgado Júnior, *A 'Menina e Moça' e o Romance Sentimental* (1940), a valuable critical study.

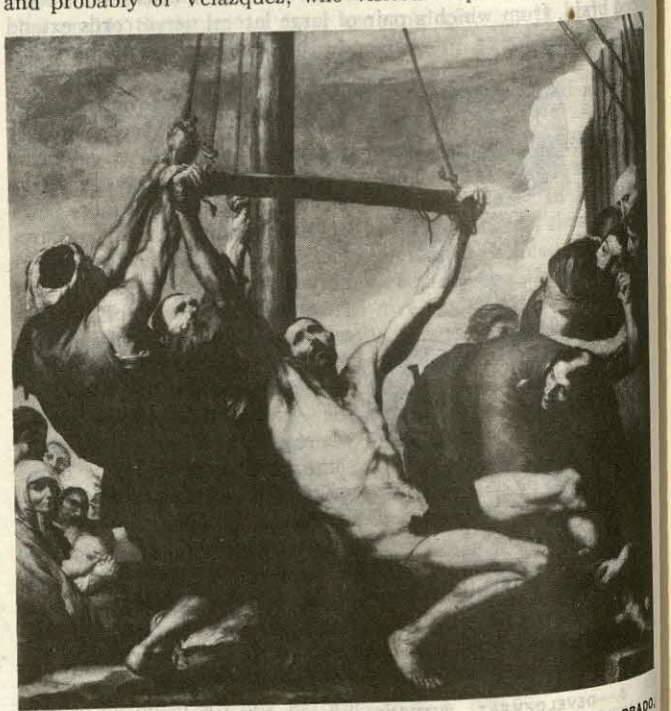
(N. J. L.)

RIBERA, JUSEPE (José) **DE** (Lo Spagnoletto) (1591–1652), Spanish painter and engraver who worked in Naples, Italy, was born at Játiva, near Valencia, but spent most of his life in Italy, where he was known as Lo Spagnoletto. Apart from his certificate of baptism (Feb. 17, 1591), there is no record of his life in Spain, though he is said by A. Palomino to have received his first training there under Francisco Ribalta. It is not known when he went to Italy but there is evidence that he worked as a young man in Parma and Rome. In 1616 he married in Naples, then under Spanish rule, where he was established during the rest of his life. In 1626 he signed as a member of the Roman Academy of St. Luke and in 1631 as a knight of the Papal Order of Christ. He died in Naples on Sept. 2, 1652.

The whole of Ribera's surviving work appears to belong to the period after he settled in Naples. His very large production comprises mainly religious compositions with a number of classical and genre subjects and a few portraits. He did much work for the Spanish viceroys, by whom many of his paintings were sent to Spain. He was also employed by the church and had numerous private patrons of various nationalities. Whether or not he first studied painting in Spain, he became in Italy one of the chief followers of Caravaggio, who formed the Neapolitan school, and he is often referred to as a Neapolitan artist.

Ribera's earliest known painting is probably the "Crucifixion" (Colegiata, Osuna), presumed to have been made for the duke of Osuna, viceroy in 1616–20. From 1621 onward there are numerous signed, dated and documented works; some of the more important are: etchings of "St. Peter" and "St. Jerome" (1621); "St. Jerome" (1626, Hermitage, Leningrad), "Drunken Silenus" (1626, Naples museum), his earliest dated paintings; "Martyrdom of St. Andrew" (1628, Budapest); "Archimedes" (1630, Prado museum, Madrid); "Portrait of a Bearded Woman" (1631, Lerma collection, Toledo); "Tityus" and "Ixion" (1632, Prado museum); "Immaculate Conception" (1635, Augustinian convent, Salamanca); "Pietà" and "Prophets" (1637–38), first commissions for the monastery of S. Martino, Naples; "Venus and Adonis" (1637, Galleria Nazionale, Rome); "Clubfooted Boy" (1642, Louvre, Paris); and "Holy Family" (1648, Metropolitan museum, New York). In 1651 he completed the "Institution of the Eucharist" (S. Martino, Naples), one of his last and most important works.

The chief elements of Ribera's style, tenebrism and naturalism, derived from Caravaggio, are used to emphasize the mental and physical suffering of penitent or martyred saints or tortured gods. Realistic detail, often horrific, is accentuated by means of coarse brush marks on thick pigment to represent wrinkles, beards, flesh wounds, etc. The influence of Bolognese and Venetian artists and probably of Velázquez, who visited Naples in 1630–31 and



ANDERSON

"THE MARTYRDOM OF ST. BARTHOLOMEW" BY RIBERA. IN THE PRADO, MADRID

1649–50, contributed to the more spacious settings, lighter tones, richer colours and more pleasing subjects which appear in Ribera's works after 1630; but he never entirely abandoned detailed realism or dramatic lighting. The objective realism of his portraits relates them to the early manner of Velázquez and to the school of Seville; while his figures of ancient philosophers in picaresque guise are typically Spanish subjects which Ribera popularized in Italy and Spain. He had many pupils and followers in Naples. In Spain his works were widely copied and imitated and were one of the chief sources of Caravaggesque naturalism. He was one of the few Spanish artists to produce numerous drawings, which were also much imitated. His etchings as well as his paintings contributed to his European fame. Like other Spanish "naturalists" he was admired and studied by 19th-century French painters.

RIBOT, ALEXANDRE FÉLIX JOSEPH (1842–1923), French statesman of the Third Republic, four times premier, was born at Saint-Omer on Feb. 7, 1842. He studied law and rose to be director of the Department of Criminal Affairs at the ministry of justice and a member of the Conseil d'État (1875), but he resigned in 1877 and was elected to represent Saint-Omer in the Chamber of Deputies. A moderate republican, he specialized in financial matters. He lost his seat in October 1885 but was returned for Pas-de-Calais in 1887 and constantly reelected. Minister of foreign affairs from March 1890 to February 1892, he initiated that *rapprochement* with Russia that was to ripen into alliance in 1894; and he resumed the portfolio of foreign affairs when he became premier on Dec. 6, 1892. In the next government (Jan. 13–March 30, 1893), he was premier and minister of the interior. Premier again and also minister of finance from Jan. 26, 1895, he sponsored the expedition to establish a protectorate over Madagascar but had to resign on Oct. 28 as a result of a financial scandal.

In opposition from 1896 to 1914, Ribot attacked the antireligious policies of Émile Combes (*q.v.*) and of the left-wing groups. He became a member of the Académie des Sciences Morales et Politiques in 1903 and of the Académie Française in 1906. He was elected senator for Pas-de-Calais in 1909. In June 1914, he was appointed minister of justice; and on Aug. 27, after the outbreak of World War I, he again became minister of finance. He retained that post till March 20, 1917, when he became premier and minister of foreign affairs. He resigned as premier on Sept. 7, 1917, but remained as foreign minister under Paul Painlevé till Nov. 13, 1917. Ribot died in Paris on Jan. 13, 1923.

Ribot's writings include *Quatre Années d'opposition,* two volumes (1905); *Lettres à un ami: Souvenirs de ma vie politique* (1924; English translation 1926); and *Journal . . . 1914–22* (1936).

RIBOT, THÉODULE ARMAND (1839–1916), French psychologist, best known for his studies in the pathology of the brain's functions, was born at Guingamp, Côtes-du-Nord, on Dec. 18, 1839. He studied medicine in Paris and became director of the first French psychological laboratory at the Collège de France. He was early impressed by the physiological and biological theories of contemporary British associationists (notably Herbert Spencer and Alexander Bain) and by the experimental researches carried out by Wilhelm Wundt at the Leipzig laboratory. He first attracted attention by his work on mental inheritance (*L'Hérédité: étude psychologique,* 1869)—a problem to which English writers had recently drawn attention—and by his survey of British psychology (*La Psychologie anglaise contemporaine,* 1870). His studies in psychopathology, like nearly all his later writings, were almost at once translated into English (*Diseases of Memory,* 1881; *Diseases of the Will,* 1884; *Diseases of Personality,* 1885). All such disorders he regarded as the direct outcome of cerebral disturbances, which he interpreted in terms of gross lesions rather than of a disorganization of the minuter structures (nerve cells and their connections); *i.e.,* as organic rather than functional. In later life he turned to the study of normal psychology (*The Psychology of Attention,* 1890; *The Psychology of Emotions,* 1897; *The Evolution of General Ideas,* 1889; *Essay on the Creative Imagination,* 1906). His systematic analyses of emotional states provided much of the material for the theories of "primary emotions" and "sentiments" subsequently developed by such British psychologists as William McDougall and A. F. Shand. Ribot died in Paris on Dec. 9, 1916. (Cy. B.)

RICARDO, DAVID (1772–1823), English economist who systematized and gave classical form to the rising science of economics, was born in London on April 19, 1772, of Jewish origin. His father, who was of Dutch birth, was a successful member of the London Stock Exchange. In 1786 Ricardo entered his father's office, where he showed much aptitude for business. After 1793, upon abandoning the Jewish faith for the Unitarian and marrying a Quaker, he was separated from his family for about eight years and was thrown upon his own resources. He continued as a member of the stock exchange, where his talents and character won him the support of an eminent banking house. He prospered immediately, and by 1815, when he prepared to retire from business, he had accumulated a large fortune. In 1819 he entered Parliament as a member for Portarlington. There he made valuable speeches on economic questions and helped bring about a change in opinion respecting freedom of trade which eventuated in the legislation of Sir Robert Peel (*q.v.*) on that subject. Ricardo died on Sept. 11, 1823, at his estate in Gloucestershire.

RADIO TIMES HULTON PICTURE LIBRARY

DAVID RICARDO, ENGRAVING AFTER A PORTRAIT PAINTED BY THOMAS PHILLIPS

His first published work on an economic subject appeared in 1809, a decade after a chance reading of Adam Smith's *Wealth of Nations* had diverted his attention from geology and mineralogy, which, along with mathematics and chemistry, had begun to interest him about 1797. His tract, *The High Price of Bullion, a Proof of the Depreciation of Bank Notes* (1810), gave a fresh stimulus to the controversy respecting the resumption of cash payments and indirectly led to the appointment of a committee of the House of Commons, commonly known as the Bullion Committee, to consider the question. The report of the committee confirmed Ricardo's views and recommended the repeal of the Bank Restriction Act, but the House of Commons declared that paper had undergone no depreciation.

In 1815, when the Corn Laws were under discussion, Ricardo published his *Essay on the Influence of a Low Price of Corn on the Profits of Stock,* directed against a tract by T. R. Malthus but based upon a theory of rent already stated by Malthus and James Anderson. In this essay are set forth the essential propositions of the Ricardian system: that an increase of wages does not raise prices; that profits can be raised only by a fall in wages and diminished only by a rise in wages; and that profits, in the whole progress of society, are determined by the cost of the production of the food which is raised at the greatest expense. These ideas were afterward incorporated in Ricardo's chief work *Principles of Political Economy and Taxation* (1817). In the field of the theory of banking and currency some of Ricardo's best work appears. His main ideas are expressed in three pamphlets: (1) *The High Price of Bullion,* in which he discusses the available means of testing the value of paper money and the power of the Bank of England to regulate the supply; (2) *Proposals for an Economical and Secure Currency* (1816), in which he elucidates the quantity theory and pronounces in favour of a monometallic standard; and (3) the *Plan for a National Bank* (1824), which was, in fact, an indictment of the methods of the existing bank, particularly in connection with its issue of paper money. In an

essay on the "Funding System" (1820), written for the Supplement to the 4th, 5th, and 6th editions of the *Encyclopædia Britannica*, Ricardo urged that nations defray their expenses, whether ordinary or extraordinary, at the time when they are incurred instead of providing for them by loans.

In his *Principles of Political Economy and Taxation*, Ricardo undertook "to determine the laws which regulate" the distribution, under free competition, of the "produce of the earth" among the "three classes of the community," namely, the landlords, the farmers, and the agricultural labourers. He applied his findings more widely, however, and elaborated various other economic principles. He found that the relative domestic values of commodities are dominated, but not wholly determined in the longer run, by the quantities of labour required in their production, rent being eliminated from the costs of production. He concluded that profits vary inversely with wages which move with the cost of necessaries; and that rent tends to increase as population grows, rising as the marginal costs of cultivation rise. He supposed, following J. B. Say, that there was little tendency to unemployment, but remained apprehensive lest population grow too rapidly, depress wages to the subsistence level, and, by extending the margin of cultivation, reduce profits and check capital formation. He concluded that trade between countries was not dominated by relative costs of production, but by differences in internal price structures which reflected the comparative advantages of the trading countries and made exchange desirable. He treated monetary questions and especially tax incidence at length.

In his exposition Ricardo usually made use of apposite hypothetical examples rather than of empirical data. While he built in part upon the work of Smith, he defined the scope of economics more narrowly than had Smith and included little explicit social philosophy. His views early won considerable support in England despite their abstract character and the many criticisms to which they were subjected. For this support Ricardo's two principal disciples were significantly responsible. J. R. McCulloch, a voluminous writer, was chosen to fill a lectureship on political economy commemorating Ricardo. James Mill, friend and political and editorial counselor to Ricardo, made of his son, John Stuart Mill, an able expounder and influential improver of the Ricardian system. Ricardo and the theories associated with his name have continued to command the critical attention of economists ever since.

His works and correspondence, in ten volumes, were edited by Piero Sraffa and M. H. Dobb for the Royal Economic Society (1951–55). *Principles of Political Economy and Taxation* appeared in several editions, including Everyman's Library. Several of the minor works were edited by J. H. Hollander.

RICCATI, JACOPO FRANCESCO, COUNT (1676–1754), Italian mathematician, whose authority on all questions of practical science was deferred to by the senate of Venice. Born at Venice on May 28, 1676, he died at Treviso on April 15, 1754. He studied at the University of Padua, where he graduated in 1696. He corresponded with many of the European savants of his day, and contributed largely to the *Acta Eruditorum* of Leipzig. He was offered the presidency of the academy of science of St. Petersburg (Leningrad), but declined, preferring the leisure and independence of life in Italy. Riccati's name is best known in connection with his problem called Riccati's equation, published in the *Acta Eruditorum*, September 1724. A complete account of this equation and its various transformations was given by J. W. L. Glaisher in the *Philosophical Transactions* (1881). His works were collected and published by his sons (4 vol., 1758).

RICCI, CURBASTRO GREGORIO (1853–1925), Italian mathematician, celebrated for the discovery of the absolute differential, or Ricci calculus, was born at Lugo, Romagna, on Jan. 12, 1853. From 1880 until his death on Aug. 7, 1925, he was professor at the University of Padua. His earliest work was in the fields of mathematical physics and differential equations. In 1887 appeared his first contribution to absolute differential calculus. Its origins are to be found in the differential geometry of G. F. B. Riemann, where it is necessary to study the behaviour of functions of partial derivatives in which the variables undergo transformation. First steps in the development of the appropriate technique of tensors had been taken by E. B. Christoffel, while important concepts had been introduced by E. Beltrami and R. O. S. Lipschitz. But the systematic theory is due to Ricci (1887–96); significant extensions were later contributed by his pupil T. Levi-Civita. For some time the new calculus found few applications; when, however, Einstein came to formulate his theory of general relativity, Ricci's methods proved to be the natural tool. The impulse given by Einstein has resulted in an intensive study of differential geometry based on the tensor calculus. (L. R.)

RICCI, MATTEO (1552–1610), Italian Jesuit missionary who with Michael Ruggieri opened China to evangelization, was born at Macerata in the march of Ancona on Oct. 6, 1552. After some education in his native town he went to study law at Rome (1568), where in 1571 he entered the Society of Jesus. He studied mathematics and geography under Clavius at the Roman college between 1572 and 1576, and in 1577, accompanied by others, he left for the Indies via Lisbon. He arrived in 1578 in Goa, where, after finishing his religious training, he taught in the college until 1582; he was then called to Macao to prepare himself for the task in China.

It was only after Alessandro Valignani became visitor of the Jesuit missions in the far east that the opening of China to Christianity was really taken up, although fruitless efforts had been made since Francis Xavier (*q.v.*). First Michael Ruggieri and then, in 1582, Ricci were summoned to Macao by Valignani for the undertaking. After various disappointments they established themselves at Ch'ao-ching, Kwangtung province, in Sept. 1583. Though never forgetting the spiritual purpose of his mission, Ricci proceeded with circumspection and contented himself with exciting the interest of the Chinese, even the more educated, with clocks, maps, European paintings and books and his own vast erudition. When in 1589 the new viceroy of Kwangtung-Kwangsi forced the missionaries to leave, Ricci obtained permission to settle elsewhere in the province in compensation for selling the mission property at a lower price. The church at Shao-chou was constructed in Chinese style and the missionaries themselves, relinquishing the costume of the despised bonzes, adopted that of the literati.

When after various misfortunes the occasion presented itself in 1595, Ricci, in the company of a high official, set out to realize his own fondest plan to establish himself in Peking. Upon arrival in Nanking, however, he found that, because of Toyotomi Hideyoshi's invasion of Korea, all foreigners were suspect and that it would be unwise to continue northward; he therefore established a new residence in Nan-ch'ang, Kiangsi province. His second chance to go to Peking came in 1597 when an official of the tribunal of rites, Kuang by name, invited Ricci to accompany him and help him compose the calendar. After waiting for two months before the gates of Peking he had to return south, again because of the Sino-Japanese conflict in Korea. He settled in Nanking until 1600 when, accompanied by two confreres, he traveled north once more. Their entrance into Peking was delayed by the intrigues of the eunuch Ma T'ang, who tried to take possession of the presents brought for the Wan-li emperor. The emperor, however, having already heard about Ricci, granted permission to enter and to offer the presents on Jan. 25, 1601. This event is recorded in the history of the Ming dynasty (Ming-shih).

They obtained a settlement with an allowance for subsistence in Peking, and from this time on to the end of his life Ricci's estimation among the Chinese increased. Besides the missionary and scientific work, from 1596 he was also superior of the mission, which in 1605 numbered 17. Ricci died on May 11, 1610, and was granted a place for burial by imperial order.

Ricci's efforts to attract and convert the Chinese intelligentsia brought him into contact with many outstanding personalities, among them Hsu Kuang-ch'i, Li Chih-tsao and Yang T'ing-yun, who later became known as the "Three Pillars of the Early Catholic Church" in China and who assisted the missionaries, especially in their literary efforts. Ricci's literary efforts include about 20

works, mostly in Chinese, ranging from religious and scientific works to treatises on friendship and local memory. Probably the most famous of his works are the "Mappamondo" and the "True Idea of God."

Ricci's "accommodation method" was the foundation of the subsequent success obtained by the Roman Catholic Church in China. The unhappy rites controversy (*q.v.*), however, which erupted shortly afterward, brought the mission near ruin. Probably the name of no European of past centuries is so well known in China as that of Li Ma-tou (Ricci Matteo).

RICCIO (ANDREA BRIOSCO) (*c.* 1470–1532), Italian sculptor, was born at Padua about 1470 and died in 1532. Trained in the workshop of B. Bellano and active principally as a bronze sculptor, he executed the great paschal candlestick for S. Antonio at Padua (1507–15) and the Girolamo della Torre monument in S. Fermo at Verona (1516–21). The bronze reliefs from the latter are now in the Louvre, Paris. The style and imagery of both works are strongly influenced by Paduan humanism. Riccio was also a prolific maker of bronze statuettes, for the most part of subjects from classical mythology. Unlike the statuettes of his contemporary Antico at Mantua, these are romantic in treatment, with marked individuality and expressive character. Outstanding examples are the "Boy Milking a Goat" in the Museo Nazionale, Florence, the "Warrior on Horseback" in the Victoria and Albert museum, London, and the "Arion" in the Louvre.

See L. Planiscig, *Andrea Riccio* (1927). (J. W. P.–H.)

RICCIO, DOMENICO (called IL BRUSASORCI) (*c.* 1516–1567), Italian painter of the Veronese school, pupil of Giovanni Francesco Caroto. He was a colourist, characterized by B. Berenson as "the first purely pictorial artist in Italy." His importance in art history is mainly the result of his being the predecessor of Paolo Veronese. There are pictures by him which resemble those of his great follower, both in design and colour; among these are the altarpieces in the churches of Sta. Eufemia and S. Lorenzo, and some single, well-preserved figures in his frescoes in the archbishop's palace at Verona. His principal works are in Verona; there are very few elsewhere. In 1551 he painted frescoes on the façade of the Casa Garavaglia in Via San Marco at Trent, representing Midas and Apollo, and a battle with Norsemen. His altarpiece at Mantua cathedral is dated 1552.

See B. Berenson, *North Italian Painters of the Renaissance* (1907); J. P. Richter, *A Descriptive Catalogue of Old Masters of Italian School in the Villa Doccia* (1907).

RICE, EDMUND IGNATIUS (1762–1844), founder and first superior general of the Institute of the Brothers of the Christian Schools of Ireland, better known as the Christian Brothers of Ireland, was born on June 1, 1762, at Callan, County Kilkenny. Inheriting a business in Waterford from his uncle, he became a prosperous merchant. Resolved to devote himself to the education of the sons of the poor, he opened his first school, in Waterford, in 1802. Further schools had been opened in Cork, Dublin, Limerick, and elsewhere when, in 1808, he and seven companions took vows and names in religion, he himself becoming Brother Ignatius. In 1820 his institute received the papal recognition that he had applied for in 1817. Ill health led to his retirement in 1838, and he died at Waterford on Aug. 29, 1844. Communities of his institute had by then been founded in England and one in Australia.

See J. D. Fitzpatrick, *Edmund Rice* (1945).

RICE, THOMAS DARTMOUTH (1808–1860), popularly known as "JIM CROW" RICE and regarded as the father of the American minstrel show, was born in New York City on May 20, 1808. He was an itinerant actor until his song and dance "Jim Crow," first presented in Louisville in 1828, caught the public fancy and made him one of the most popular specialty performers of his day. Although he was not the first entertainer to impersonate a Negro, Rice created a vogue for such impersonations in both the U.S. and England through a series of extremely successful tours. He wrote and appeared in *Ginger Blue, Jim Crow in London,* and a burlesque of *Othello.* These engendered the stereotypes for the skits in the popular minstrel shows which evolved in the 1840s, primarily as a result of Rice's success. Rice died in poverty at New York on Sept. 19, 1860.

See also MINSTREL SHOW. (O. G. B.)

RICE, a well-known cereal, is the staple food of hundreds of millions of people in Asia. Cultivated rice, *Oryza sativa,* was first mentioned in history in 2800 B.C. when a Chinese emperor proclaimed the establishment of a ceremonial ordinance for the planting of rice. Other authorities have traced the origin of rice to a plant grown in India in 3000 B.C. Rice culture gradually spread westward from southeastern Asia with the passage of time and was introduced to southern Europe in medieval times by the invading Saracens. This article briefly summarizes the botanical characteristics of rice and discusses its cultivation, preparation for the market and production. For additional information *see* TROPICAL AGRICULTURE; GRAIN PRODUCTION AND TRADE; FOOD SUPPLY OF THE WORLD; CEREALS.

See also articles on various rice-growing countries, as CHINA; etc.

The cultivated rice plant, an annual grass about 4 ft. tall, has numerous varieties that differ markedly in morphological characters and in physiological behaviour. It originated from wild species which are indigenous to Africa, India and Indochina. The rice plant has long, flattened leaves, about 2 ft. long and ½ in. wide, each provided with a pointed membranous structure called a ligule, where the leaf arises from the sheath, which surrounds the culm, or stem. The spikelets are borne on a loose panicle, which is erect at blooming, but nodding as the grains develop and mature. Each spikelet contains one flower enclosed by the compressed lemma and palea. At the base of each of these organs is a small lance-shaped glume. (Lemma, palea and glume are modified leaves, or bracts, typical of grass inflorescences.) The flower consists of six stamens and an ovary surmounted by two styles bearing a feathery stigma. The ovary, after fertilization, develops into the fruit or grain, which is enclosed by the lemma and palea, or hull. Most varieties are grown on submerged land, but others, known as upland rice, are grown on land not submerged.

PANICLE OF RICE

Cultivation.—Rice is grown in coastal plains, tidal deltas and river basins in tropical, semi-tropical and temperate regions where fresh water is available to submerge the land. In the Orient, where most of the farms are too small for the use of farm machinery, rice is generally grown by hand labour, although animals, when available, are used in preparing the land. The rice is sown broadcast on well-prepared beds, and when the seedlings are 25 to 50 days old they are transplanted to the field, or paddy, by hand. Before transplanting, the fields, which are enclosed by levees, or bunds, are submerged 2 to 4 in. and the surface soil is

thoroughly stirred. Two to five seedlings are placed in hills 3 to 6 in. apart in rows 8 to 12 in. apart. The land is submerged during most of the growing season, and the crop is harvested by hand. About 95% of the world's rice is produced in Asia and the Japanese, Philippine, Indonesian and other nearby islands.

Outside of the Orient, farm machinery usually is used for preparing the land, seeding and harvesting. The crop is grown in essentially the same manner as wheat, oats and barley, except that the land is submerged during most of the growing season. The principal rice-producing countries outside of the Orient are Egypt, Italy, Spain, Brazil and the United States. Rice was introduced to North America in the colony of South Carolina about 1685. By 1839 South Carolina produced 60% of the rice grown in the United States. Other rice-producing states were North Carolina and Georgia. The American Civil War and the Reconstruction period adversely affected this crop but rice acreage increased along the Mississippi River in Louisiana, becoming an important crop in this state with the introduction of mechanized farming methods. Commercial production of rice began in Arkansas, Texas and in the Sacramento Valley of California about the turn of the century. In the second half of the 20th century, many farmers broadcast seed and fertilizer by airplane on submerged land while others seed and fertilize their fields with a grain drill.

Preparation of Rice.—The kernel of rice as it leaves the thresher is enclosed by the hull, or husk, and is known as paddy or rough rice. Rough rice is used for seed and feed for livestock, but most of it is milled for human consumption by removing the hulls. Rice is a good energy food, and is consumed in vast quantities in the Orient. In the Western Hemisphere, however, rice is not the staple cereal food, except in certain Caribbean islands. A diet limited largely to well-milled rice renders people on a restricted diet liable to beriberi (*q.v.*), a deficiency disease caused by a shortage of essential thiamine (vitamin B_1) and minerals, which are present in adequate amounts in the whole grain. This disease, however, can be avoided by adding legumes, fish, fruits and vegetables to the diet.

Rough rice that is parboiled and dried prior to milling retains more thiamine and minerals than untreated rice, and hence is less apt to cause beriberi. It appears that in parboiling, the thiamine, which is largely in the germ and bran layers of the kernel, diffuses into and is fixed in the starchy endosperm.

Most of the rice is milled in or near the areas in which it is produced. In modern mills, special machines are used for removing the hull from the kernel, for removing the bran layers by attrition, for polishing, for coating and for grading. The object in milling is to remove the hull and the bran layers of the kernel with as little breakage as possible, for the most valuable product is the whole kernel. Milled rice is sometimes coated with glucose and talc to give a high glossy finish. The by-products of milling—bran and rice polish (finely powdered bran and starch resulting from polishing)—are used as feed for livestock, and oil is processed from bran for edible and industrial uses. Broken rice is used in brewing, distilling and manufacturing starch and rice flour. The hulls are used for fuel, packing, poultry litter, manufacturing furfural, industrial grinding and manufacturing fertilizer. Straw is used for feed, bedding livestock, thatching roofs and for mats, garments, packing and broomstraws.

World Production.—In the second half of the 20th century the world rice crop averaged between 360,000,000,000 and 460,000,000,000 lb. annually, from an average of about 250,000,000 ac. The average acre yield for the world was about 1,450 lb.

Principal producing countries included China, India, Japan, Pakistan, Indonesia, Thailand and Burma.

Annual rice production in the United States averaged about 5,000,000,000 lb. from an average of less than 2,000,000 ac. The average acre yield was more than 3,000 lb. Leading producing states were Texas, Louisiana, Arkansas, California and Mississippi.

RICE, WILD (*Zizania aquatica*), or Indian rice, water oats, also known locally by many other names, is an indigenous, coarse, annual grass, the grain of which has long been used as an important food by various Indian tribes and early settlers. It is commonly found on muddy bottom in fresh to brackish water along shores, streams, or in lakes and swampy places from the Atlantic coast west to the Mississippi Valley and is widely planted as food for waterfowl. This self-sowing grass, 4 to 8 ft. high, has a fruiting panicle up to 2 ft. long, the lower spreading branches of which bear male flowers whereas the upper erect branches bear female flowers. When well cooked, the slender, round, purplish black, starchy grain (nearly $\frac{3}{4}$ in. long) is delicious.

Among northern Indians "ricing" means harvesting wild rice by canoe and preparing it for winter storage. The primitive methods employed by them still yield a superior product. Unless kept in wet, cool storage, wild rice loses its viability. (T. K. J.)

RICH, BARNABE (1542–1617), English author and soldier whose *Farewell to Militarie Profession* was the source for *Twelfth Night*, was born in 1542. He entered military service in 1562 and fought in the Low Countries and Ireland, eventually becoming a captain and a self-styled gentleman. Later he was an informer for the crown in Ireland, under Elizabeth I, and, again, under James I. He died on Nov. 10, 1617.

Rich wrote at least 26 books, including five romances and translations, five military works, seven reports on Ireland, six commentaries on manners and morals, and three miscellaneous pamphlets. *Riche His Farewell to Militarie Profession* (1581), a collection of eight tales, is the best-known because of Shakespeare's borrowings in *Twelfth Night*. Though in this he emulated the euphuistic prose of John Lyly and appealed to English gentlewomen, ordinarily Rich boasted of his self-education, his "homely style" and his freedom from the affectations of the university. Despite his fulminations against iniquities in such tracts as *The Honestie of This Age* (1614), he appropriated material from other books and exhibited many of the hack writer's tactics of exploitation.

RICH, EDMUND: *see* EDMUND, SAINT.

RICH, JOHN (1682?–1761), English theatre manager and actor, was the originator of English pantomime and founder of Covent Garden Theatre. He was a manager by inheritance, receiving a half share in Lincoln's Inn Fields Theatre from his father, Christopher Rich (d. 1714), and after running that house successfully for 18 years he founded Covent Garden Theatre (1732). At both he staged entertainments of a new type based on Italian foundations, known as pantomime, in which, from 1717 until the year before his death, he played Harlequin (*q.v.*) under his stage name of Lun. He has thus a claim to be the inventor of the harlequin-

ade of English pantomime tradition. After Rich's death David Garrick paid tribute to the matchless expressiveness of his miming.

Rich has another special claim to be remembered. In 1727 he was offered John Gay's Newgate pastoral *The Beggar's Opera*, which Drury Lane had refused. Rich appreciated Gay's satire and produced the play on Jan. 29, 1728, at Lincoln's Inn Fields Theatre. It ran 62 performances, the longest then known, and, as was said at the time, "made Gay rich and Rich gay." (W. A. Dn.)

RICH, RICHARD RICH, 1st Baron (*c.* 1496–1567), lord chancellor of England, was born in the parish of St. Lawrence Jewry, London. Richard, a lawyer of the Middle Temple and M.P. for Colchester (1529), held various minor offices before becoming solicitor general in 1533. He took part in the trials of Sir Thomas More and Bishop Fisher, seeking their conviction, and was one of Thomas Cromwell's agents in the dissolution of the monasteries, himself obtaining large grants of monastic property. In 1536 he was M.P. for Essex and speaker of the House of Commons. That year also he was knighted and became the first chancellor of the newly established Court of Augmentations. By August 1540 he was a privy councilor. He was one of the executors of Henry VIII's will, was created Baron Rich in February 1547, and became lord chancellor in October. In October 1549 he joined the earls of Warwick and Southampton in overthrowing the duke of Somerset, the Protector, over whose trial he presided. He resigned the lord chancellorship, on grounds of ill-health, in December 1551, at the time of the final breach between Warwick (now duke of Northumberland) and Somerset. Like other councilors, he had to subscribe Edward VI's settlement of the succession on Northumberland's daughter-in-law, Lady Jane Grey, but after Edward VI's death he soon declared for Mary Tudor, whose religious policy he now supported, although henceforward he did not take a prominent part in public affairs. A "civil servant" rather than a politician, he had never been a heroic or a very attractive figure. He died at Rochford, Essex, on June 12, 1567, and was buried in Felsted Church. (R. B. Wm.)

RICHARD I (1157–1199), king of England, nicknamed "Coeur de Lion" and "Yes and No," was the third son of Henry II and Eleanor of Aquitaine. Born on Sept. 8, 1157, he was given the duchy of Aquitaine, his mother's inheritance, at the age of 11, and was enthroned as duke at Poitiers in 1172. In 1169 he had been betrothed to Alice, second daughter of Louis VII of France and Constance of Castile. Richard possessed precocious political and military ability, quickly won fame for his knightly prowess, and quickly learned how to control the turbulent aristocracy of Poitou and Gascony. Like all Henry II's legitimate sons, he had little or no filial piety, foresight, or sense of responsibility. He joined his brothers in the great rebellion (1173–74) against Henry II, who invaded Aquitaine twice before Richard submitted and received pardon. Thereafter Richard was occupied with suppressing baronial revolts in his own duchy. It was in crushing these that he made his lifelong reputation as a brilliant soldier: in 1179 he captured the supposedly impregnable fortress of Taillebourg in Saintonge. His harshness infuriated the Gascons, who revolted in 1183 and called in the help of the "Young King" Henry and his brother Geoffrey of Brittany in an effort to drive Richard from his duchy altogether. Alarmed at the threatened disintegration of his empire, Henry II brought the feudal host of his continental lands to Richard's aid, but the younger Henry died suddenly (June 11, 1183) and the rising collapsed.

Richard was now heir to England and to Normandy and Anjou (which were regarded as inseparable), and his father wished him to yield Aquitaine to his youngest brother John. But Richard, a true southerner, would not surrender the duchy in which he had grown up; and even appealed, against Henry II, to his close friend the young king of France, Philip II (Philip Augustus). At Bonmoulins, near Mortagne (now in the Orne *département*), he did homage (Nov. 18, 1188) to Philip for all the Angevin lordships on French soil, although his father was present. In 1189 Richard openly joined forces with Philip to drive Henry into abject submission. They chased him from Le Mans to Saumur, forced him to acknowledge Richard as his heir, and at last harried him to his death (July 6, 1189).

So far Richard had proved himself as a soldier and given promise of political adroitness. Now, after his accession to Normandy (July 20) and England (Sept. 3, 1189), he was to show himself a match even for Philip of France, the ablest ruler of his time in Western Europe. Richard, however, unlike Philip, had only one ambition, to lead the crusade prompted by Saladin's capture of Jerusalem in 1187. He had no conception of planning for the future of the English monarchy. Consequently, his policy in 1189 was to put everything up for sale, to buy allies, troops, ships, and munitions, regardless of the harm which the crown might suffer in consequence. Yet he had not become king to preside over the dismemberment of the Angevin empire. He broke with Philip of France and did not neglect Angevin defenses on the continent. Open war was averted only because Philip also took the cross. Richard dipped deep into his father's treasure, sold sheriffdoms and other offices, and for 10,000 marks released the king of Scots from the vassalage forced on him after his capture by Henry II in 1174. With all this he raised a formidable fleet and army and in 1190 departed for the Holy Land, traveling via Sicily. While in Sicily he repudiated his fiancée, Philip's sister Alice.

GIRAUDON

RICHARD COEUR DE LION, TOMB EFFIGY IN THE ABBEY CHURCH OF FONTEVRAULT, FRANCE

Richard found the Sicilians hostile and took Messina by storm (Oct. 4). To prevent the German emperor Henry VI from ruling their country, the Sicilians had elected the native Tancred of Lecce, who had imprisoned the late king's queen, Joan of England (Richard's sister), and denied her possession of her dower. By the Treaty of Messina Richard obtained for Joan her release and her dower, acknowledged Tancred as king of Sicily, declared Arthur of Brittany to be his own heir, and provided for Arthur to marry Tancred's daughter. Ominously, this treaty infuriated the Germans, who were also taking part in the Third Crusade, and it incited Richard's brother John to treachery and rebellion. Richard joined the other crusaders at Acre on June 8, 1191, having conquered Cyprus on his way there. While at Limassol, Richard married (May 12) Berengaria, daughter of Sancho VI of Navarre.

Acre fell in July 1191, and on Sept. 7 Richard's brilliant victory at Arsuf put the crusaders in possession of Joppa. Twice Richard led his forces to within a few miles of Jerusalem. But the recapture of the city, and the reconquest of the Christian feudal principalities of the Levant, which constituted the chief aim of the Third Crusade, eluded him. There were fierce quarrels between the main Western contingents, French, German, and English; more seriously there was a fundamental difference of outlook and policy between the Westerners as a whole and the resident Frankish nobility of the Latin kingdoms. The Westerners wanted spectacular victories and were ruthless and aggressive toward the Muslim. Richard, for example, allowed 2,600 prisoners to be massacred at Acre. The resident "Easterners" were half converted to an Oriental manner of living and more tolerant toward the Muslim. Richard insulted Duke Leopold of Austria by tearing down his banner and quarreled with Philip Augustus, who returned to France after the fall of Acre. Richard's candidate for the crown of Jerusalem was his vassal Guy de Lusignan, whom he supported against the German candidate Conrad of Montferrat. It was rumoured, unjustly, that Richard connived at the murder of Conrad by the Assassins. After a year's unproductive skirmishing, Richard (September 1192) made a truce for three years with Saladin which permitted the crusaders to hold Acre and a thin coastal strip and gave Christian pilgrims free access to the Holy Places.

Richard sailed home by way of the Adriatic, because of French hostility, and a storm drove his ship ashore near Venice. Because of the enmity of Leopold of Austria he disguised himself, but was

discovered at Vienna in December 1192 and imprisoned in the duke's castle at Dürrenstein on the Danube. Later, he was handed over to Henry VI, who kept him at various imperial castles. It was round Richard's captivity in a castle whose identity was at first unknown in England that the famous romance of Blondel was woven in the 13th century. Under the threat of being handed over to Philip II, Richard agreed to the harsh terms imposed by Henry VI: a colossal ransom of 150,000 marks and the surrender of his kingdom to the emperor on condition that he receive it back as a fief. The raising of the ransom money was one of the most remarkable fiscal measures of the 12th century and gives striking proof of the prosperity of England. The money was found chiefly by levying an aid of £1 on each knight's fee and imposing a general tax of one quarter of rents and movable goods. Ultimately a very high proportion of the ransom was paid, and meanwhile (February 1194) Richard was released.

He returned at once to England and was crowned for the second time on April 17, fearing that the independence of his kingship had been compromised. Within a month he went to Normandy, never to return. His last five years were spent in warfare against Philip II, interspersed with occasional truces. The king left England in the capable hands of Hubert Walter, justiciar and archbishop of Canterbury. Richard's conduct of the war showed that he had lost none of his early vigour and that he had learned something of the art of fortification while in the East: in 1196 he built the famous Château-Gaillard on the island of Andely in the Seine to guard the border between the Norman and the French Vexin, while in battles and skirmishes he was nearly always victorious. It was his characteristic impetuosity which brought him to his death at the early age of 42. The vicomte of Limoges refused to hand over a hoard of gold unearthed by a local peasant. Richard laid siege to his castle of Châluz, and in an unlucky moment was wounded. He died on April 6, 1199. He was buried in the abbey church of Fontevrault, where Henry II and Queen Eleanor are also buried, and his effigy is still preserved there.

Richard was a thoroughgoing Angevin, irresponsible and hot-tempered, possessed of tremendous energy. He was more accomplished than most of his family, a soldier of consummate ability, a skilful politician, capable of inspiring loyal service, and, last but not least in the eyes of his own age, a lyric poet of considerable power and the hero of the troubadours. But there was a cold, cruel side to his character, and in striking contrast with his father and with King John he was, there seems no doubt, a homosexual. He had no children by Queen Berengaria, with whom his relations seem to have been merely formal. As king of England, Richard brought the country great honour and prestige through his own crusading prowess, but he made no contribution to its government and recklessly commercialized royal offices and privileges. Of his reign of ten years, he spent only six months in England.

(G. W. S. B.)

RICHARD II (1367–1400), king of England from 1377 to 1399, younger son of Edward the Black Prince by his cousin Joan of Kent, was born at Bordeaux on Jan. 6, 1367. Created prince of Wales on Nov. 20, 1376, he succeeded his grandfather Edward III as king on June 22, 1377. Government during his minority was in the hands of councils nominated in Parliament, and little is heard of Richard until the Peasants' Revolt of 1381, when he displayed great courage and presence of mind in pacifying the rebels in London on June 14–15. Despite this exciting taste of power, the young king was allowed little influence, and until 1386 his uncle, John of Gaunt, duke of Lancaster, remained the most powerful figure in government. The Parliament of 1381 expressed concern about Richard's education and associates, and Richard Fitzalan, earl of Arundel, and Michael de la Pole (afterward earl of Suffolk) were appointed "to counsel and govern" the king's person. In January 1382 Richard was married to the emperor Charles IV's eldest daughter, Anne of Bohemia, to whom he became deeply devoted. His sensitive interest in literature and art was later expressed in his patronage of Chaucer, Gower, and Froissart, and in the rebuilding of Westminster Hall; but he had no taste for the warlike and chivalric pursuits so admired by his contemporaries. His Scottish expedition of 1385 proved an expensive promenade which achieved little success. By then a "court party" was beginning to form around the young king. Its nucleus was a group of chamber knights, organized by his tutor and acting chamberlain, Sir Simon Burley, but its most prominent figure was the vapid and frivolous Robert de Vere, earl of Oxford, Richard's closest friend and favourite. The courtiers soon became unpopular for their greed and extravagance. Their influence encouraged Richard to rebel against his tutelage. As early as April 1384 he had thrown off the control of Arundel, whom he hated, and had quarreled with his uncles, Lancaster and Thomas of Woodstock (afterward duke of Gloucester). He soon showed himself unduly sensitive to any criticism, and answered Archbishop William Courtenay's complaints about his household by drawing a sword and threatening to strike him down.

The first major crisis of the reign was provoked by Lancaster's leaving England in July 1386 to pursue his private dynastic ambitions in Castile. The removal of the moderating Lancastrian influence brought the royalists face to face with the hostility of Gloucester, Arundel, Thomas de Beauchamp, earl of Warwick, and other lords, who despised Richard for his indifference to war, for his dependence on a small circle of friends, and for the excessive favour shown to de Vere, who was created duke of Ireland in October 1386. When this opposition tried to make the chancellor, de la Pole, now earl of Suffolk, a scapegoat for the unpopular policies of previous years, Richard came to his defense, haughtily telling the Parliament of 1386 that he would not remove a scullion from his kitchen at their request. But parliamentary pressure was too great; Suffolk was dismissed and impeached, and a continual council was appointed with wide powers, to prolong the king's subjection to magnate control. In his resentment Richard began to recruit a bodyguard of archers from his Cheshire palatinate, and in August 1387, at Nottingham, he obtained from the judges a statement of the royal prerogative, which branded as treasonable some of the opposition's recent acts. In November 1387 Gloucester and his allies demanded the arrest of Suffolk, de Vere, and other royalists. Richard permitted their escape, and de Vere assembled an army in the northwest which marched on London, only to be dispersed by the magnates at Radcot Bridge in December 1387. Richard now had to pay the penalty for his rash defiance. His supporters were declared guilty of treason and attainted in the "Merciless Parliament" of 1388 by five lords appellant, and those who could be apprehended, including the faithful Burley, were put to death. The defenseless king had to submit to appellant control until May 3, 1389, when he declared his intention to rule freely as a monarch of full age.

BY COURTESY OF THE DEAN AND CHAPTER OF WESTMINSTER ABBEY

RICHARD II, PORTRAIT BY AN UNKNOWN ARTIST. IN WESTMINSTER ABBEY, LONDON

Lancaster's return from Spain in November 1389 began "the period of appeasement" when the king worked in apparent harmony with Gaunt and the barons. It is unlikely, however, that Richard had forgiven his humiliations in 1387–88, and he was cautiously waiting the opportunity to avenge himself on the appellants. Gradually he attracted to himself a second and stronger royalist party, including magnates like his cousin, Edward of York, earl of Rutland, and new men such as the notorious Sir John Bussy, Sir William Bagot, and Sir Henry Green. Meanwhile, his first Irish

expedition (1394–95) brought him some prestige, and his prudent conciliation of France led in 1396 to a further extension of the truce of Leulinghen (1389) and his marriage to the French princess, Isabella (Queen Anne had died in 1394).

By 1397 Richard felt strong enough to attack his former enemies. After being convicted of treason in the Parliament of September 1397, Arundel was executed, Warwick banished, and Gloucester murdered in his Calais prison. In September 1398 the famous quarrel between the two younger appellants, Gaunt's son, Henry Bolingbroke, and Thomas Mowbray, duke of Norfolk, enabled the king to order their summary banishment. Richard had now embarked on a policy which some historians believe was designed to establish an arbitrary despotism. Yet many of his acts were inspired by motives of revenge; others, such as his violent resentment of any pretended affront to the crown, reflect the growing unbalance of his character in later years. He did little to create the institutions of despotism, and the suspicion that he intended to supersede Parliament cannot be proved. His obsession with the pageantry of kingship and his high view of the prerogative and the divine character of his office suggest a ruler more concerned with the outward trappings of monarchy than with the less spectacular substance of power. His final acts of folly were his confiscation of the Lancastrian estates after Gaunt died on Feb. 3, 1399, followed by his departure for Ireland at the end of May. These provided the justification and opportunity for Gaunt's heir, Henry Bolingbroke, the future Henry IV, to invade England in July. Few of Richard's subjects were willing to defend him, and the majority approved the deposition of a king whose caprice and malice had alienated their loyalty. On his return from Ireland, Richard was tricked into surrender at Conway in August 1399, and on Sept. 30 was compelled to abdicate his throne. On Oct. 28 he was sent to Pontefract Castle, where he died in February 1400, probably of starvation, which may have been self-inflicted. Shakespeare's story of his murder by Piers Exton, a squire of Henry's, rests on no reliable authority.

(C. D. R.)

RICHARD III (1452–1485), king of England, youngest son of Richard, duke of York, by Cicely, daughter of Ralph Neville, 1st earl of Westmorland, was born at Fotheringhay castle on Oct. 2, 1452. At the coronation of his eldest brother Edward IV in June 1461 he was created duke of Gloucester. In contrast to his brother George, duke of Clarence, he was faithful to Edward IV and accompanied him into exile in 1470. On their return in 1471 he commanded with distinction the van at the battles of Barnet and Tewkesbury. According to Tudor historians, after the latter battle he stabbed to death in cold blood Queen Margaret's son Edward, the Lancastrian heir; but the contemporary evidence suggests that the prince was killed in battle. There is, however, strong testimony that Richard was implicated in the murder of Henry VI on the night of May 21–22, 1471, when he was certainly present in the Tower of London. For his services and fidelity he was rewarded with large grants of land and offices, and by marrying Anne (1456–85), younger daughter of Richard Neville, earl of Warwick, he secured a claim to half the vast Neville inheritance. This was resented by his brother, the duke of Clarence, who had already married the elder sister Isabel. The breach between them was never healed, but Richard does not seem to have been implicated in Clarence's death in 1478; this was a much later charge, developed in Tudor days.

Richard's share of the Neville inheritance was chiefly in the north; and in view of his proved ability and fidelity Edward IV used this as a foundation on which to build Richard's power in the north to viceregal proportions, to bring order and effective royal authority to this turbulent region. Eventually Richard was made king's lieutenant general in the north (1480) and hereditary warden of the west marches (1483). He used his powers with efficiency and wisdom to promote peace and justice and became much beloved in the north. To help him in the administration he instituted a council, which was the forerunner of the later celebrated council of the north. In 1482 he commanded a successful expedition into Scotland and recaptured Berwick-upon-Tweed.

RICHARD III, PORTRAIT BY AN UNKNOWN ARTIST

The reputation which he had built up in the north helped him on the death of Edward IV (April 1483). His brother had named him protector during the minority of his young son, Edward V, and the old nobility and the administrators of Edward IV supported him against the upstart Woodvilles, relations of Edward IV's queen, Elizabeth. The young king had been brought up by the queen's kindred, and Richard feared that through their influence over the boy they would dominate the government and effect his destruction. Hence he arrested the king's escorts and maternal relatives, Lord Rivers and Sir Richard Grey, at Stony Stratford (April 30, 1483) and took Edward V under his own protection. Later Rivers and Grey were executed. The Woodville faction was overthrown and the queen with her younger children took sanctuary at Westminster. Loyal supporters of the young king may have become alarmed at Richard's growing power and conspired against him; at any rate on June 13 he suddenly arrested Lord Hastings, John Morton, bishop of Ely, and Lord Stanley, and beheaded Hastings the same afternoon. By now it was probably too dangerous for him not to go forward; and on June 22, a friar, Ralph Shaw, was put up at St. Paul's cross to preach against the legitimacy of Edward IV's children. On June 25 an assembly of the three estates of the realm met in London and declared that Edward's marriage was invalid on the ground of his precontract with Eleanor Butler, daughter of John Talbot, 1st earl of Shrewsbury, and that Richard was rightful king. Richard accepted the proffered crown and from the following day began his formal reign.

On July 6 Richard was crowned at Westminster and immediately afterward made a royal progress through the midlands, on which he was well received. But he could not be secure while his nephews were alive. Queen Elizabeth Woodville had been induced to give up Edward's younger brother Richard and both he and Edward were lodged in the Tower of London. There seems to be little doubt that early in August they were murdered there by their uncle's orders. Attempts have been made to clear Richard's memory (*see* EDWARD V). But the report of the princes' death was believed in England at the time and it was referred to as a definite fact before the French estates-general in Jan. 1484. Richard never produced the boys to refute the charge, and for the alternative explanations of their disappearance no evidence (as distinct from speculation) has ever been offered.

The widespread disquiet in the south of England found expression in the duke of Buckingham's rebellion (Oct. 1483). Richard was lucky, however, and the revolt collapsed. But the defection of Buckingham and his supporters reduced still further the unsure foundation of Richard's power, a base rendered even more insecure by the death of his only son, Edward, in April 1484 and of his wife in March 1485. He tried hard to live down the past and gain support by his energy and devotion to his kingly duties. He showed zeal for trade and English interests abroad; he tried to repress disorder and promote justice; he made it easier for poor suitors to present their petitions to him and his council; he strove to make financial reforms and lessen the burden of royal demands for money. He endeavoured to win support among the

clergy by his tenderness for their privileges, his building of churches, his advocacy of morality, his patronage of learning. He strove to win the approval of the people by his magnificent dress, his princely building, his care for heraldry and pageantry, his liberality, his magnanimity toward the dependents of some of his fallen opponents, his many recorded acts of kindness to petitioners in distress. Given time, he might hope, like King John, to live down the murder of a boy heir and to die as a favoured son of the church. But time was not on his side; the support of the aristocracy and the gentry had been so largely alienated that the many timeservers among his remaining adherents doubted his power to survive. And public opinion was scandalized by the rumour that Richard intended, on the death of his wife, to marry his niece, Elizabeth of York. His rival Henry Tudor (later Henry VII) was joined in France by supporters of Edward IV, the Woodvilles, the Lancastrians and of Buckingham, and was encouraged by the French government, which was alarmed by Richard's declared intention to maintain English claims in France. On Aug. 7, 1485, Henry Tudor landed at Milford Haven, and, gathering support as he marched east, met Richard at Bosworth on Aug. 22. Richard had the larger forces, but the earl of Northumberland was disaffected, and the issue was decided by the treachery of Lord Stanley, Henry's stepfather, and his brother Sir William Stanley. Richard refused to flee and died fighting bravely against overwhelming odds. After the battle his bloody and naked body was carried to Leicester, trussed across a horse's back, and buried without honour in the church of the Greyfriars.

His reputation in Tudor days as a monster of unparalleled villainy was largely because of the fact that he had too little time to live down his deeds of 1483 and the fact that in Tudor England it was impolitic to vindicate his memory. As for the allegation that he was a hunchback, neither the portraits of Richard nor contemporary evidence testifies to any such deformity, though there is some indication that one shoulder was higher than the other. *See* also references under "Richard III" in the Index.

RICHARD, EARL OF CORNWALL and KING OF THE ROMANS (1209–1272), second son of John, king of England, born at Winchester (Jan. 6, 1209), was knighted and given the title "count of Poitou," and the county and tin mines of Cornwall (1225). On returning from his unsuccessful expedition to recover Poitou (March 1225–May 1227) he was created earl of Cornwall (May 30, 1227). Between 1227 and 1238 he frequently opposed his brother King Henry III, joining the barons in several crises, but never proceeding to rebellion and always making Henry pay heavily for reconciliation. He married (March 30, 1231) Isabella, daughter of William Marshal, earl of Pembroke, and widow of Gilbert de Clare, 6th earl of Gloucester; of their four children only Henry (of Almain) survived.

Richard joined Henry III's inglorious Breton expedition (1230); he took the cross (1236), and after Isabella's death (Jan. 17, 1240) led a small English force to the Holy Land (June 1240–January 1242) refortifying Ascalon and negotiating an advantageous treaty. During Henry's disastrous Poitevin campaign (1242), Richard's prompt retreat at Saintes and his persuasive diplomacy at Taillebourg saved Henry from capture. Richard married Sanchia of Provence, sister of Henry's queen (Nov. 23, 1243), abandoning his Poitevin title a few days later; his second surviving son, Edmund, was born of this marriage, which bound Richard closely to Henry's circle. As farmer of the mint he executed and financed the great recoinage of 1247–48, making £20,000 profit thereby. While acting regent of England during Henry's Gascon visit (1253–54), Richard summoned knights to represent the shires at the critical Parliament of Easter 1254. He founded and built the Cistercian Abbey of Hailes (1245–46). Reputedly the richest magnate in England, he refused Pope Innocent IV's offer of the Sicilian crown (1252–53), but accepted imperial candidature (1256), purchased four of the seven electoral votes, was elected king of the Romans and crowned at Aachen (May 17, 1257) by the archbishop of Cologne. By lavish bribery he gained recognition throughout the Rhineland, returning home in January 1259. He helped Henry to overthrow the Provisions of Oxford, but from June to October 1260 he again visited Germany, now discovering the absurdity of his hopes of the imperial crown. His third visit to Germany (June 1262–February 1263) also achieved nothing useful. He helped Henry invaluably against the rebel barons (1263–64) but was captured at Lewes (May 14, 1264) and imprisoned at Wallingford and then at Kenilworth until the overthrow of Simon de Montfort at Evesham (Aug. 4, 1265). Ably supported by his son Henry, he then worked ceaselessly to obtain the relatively moderate settlement of the *Dictum de Kenilworth* (Oct. 31, 1266). His fourth visit to Germany (August 1268–August 1269) is notable only for his third marriage, to Beatrice of Falkenburg (June 16, 1269). The murder of his son Henry at Viterbo (March 13, 1271) was a deadly blow to Richard, who died at Berkhamstead Castle on April 2, 1272.

RICHARD OF ST. VICTOR (d. 1173), theologian noted for his mystical treatises, was born in Scotland or England. He entered the Abbey of St. Victor in Paris, where he was a student of Hugh of St. Victor and where he became prior in 1162. Although Richard wrote doctrinal treatises on the Trinity and exegetical studies of the Scriptures, it is for his works on mysticism, which synthesize and elaborate Victorine teachings, using extensive symbolism, that he is chiefly remembered. They reflect the influence of Neoplatonism, St. Augustine, and especially Dionysius (*q.v.*) the Areopagite. According to Richard, the soul proceeds by six successive steps from sense perception to ecstasy, using the faculties of imagination, reason, and intuition, and employing secular learning as well as divine revelation, until it is finally carried beyond itself and united with God in divine contemplation. Richard profoundly influenced medieval mysticism, as exemplified by St. Bonaventura and Jean de Gerson, and also early modern mysticism, as is evidenced by the appearance of six editions of his works between 1506 and 1650. Dante placed Richard among the greatest teachers of the church. His collected works are published in volume cxcvi of J. P. Migne's *Patrologia latina*. (D. D. McG.)

RICHARDS, DICKINSON WOODRUFF (1895–), U.S. physiologist and Nobel laureate, noted for research on the human heart, was born at Orange, N.J., on Oct. 30, 1895. He graduated from Yale University in 1917, took a master's degree at Columbia University in 1922, and received his medical degree from Columbia the next year. After study in England he began his research in heart and lung physiology at the College of Physicians and Surgeons, Columbia, in 1928. From 1947 to 1961 he was Lambert professor of medicine there and was professor emeritus thereafter; and from 1945 to 1961 he was director of the Columbia medical division at Bellevue Hospital in New York City.

Adapting the pioneer experiments of Werner Forssmann (*q.v.*), Richards and André Frédéric Cournand (*q.v.*) measured blood pressure and other conditions inside the heart by means of cardiac catheterization (*q.v.*), and later extended the measurements to the lungs and general circulatory system. This research suggested new methods of diagnosing and treating heart disease and led to discoveries concerning the effects of disease and drugs on circulation. Richards shared the 1956 Nobel Prize in medicine with Cournand and Forssmann.

RICHARDS, THEODORE WILLIAM (1868–1928), U.S. chemist, received the Nobel Prize for Chemistry in 1914 for his researches on atomic weights (*q.v.*). He was born in Germantown, Pa., on Jan. 31, 1868. He graduated from Haverford College, Pa., (1885) and took advanced degrees at Harvard, where he became instructor in chemistry in 1891 and full professor in 1901.

Richards greatly improved the technique of gravimetric atomic weight determinations, introducing quartz apparatus, the bottling device, and the nephelometer (an instrument for measuring turbidity). Although the atomic weight values of Jean Servais Stas had been regarded as standard, about 1903 physicochemical measurements showed that some were not accurate. Richards and his

students revised these figures, lowering, for instance, Stas's value for silver from 107.93 to 107.88. Richards' investigations of the atomic weight of lead from different sources helped to confirm the existence of isotopes. His later researches were concerned mainly with the physical properties of the solid elements, and included much original work on atomic volumes and compressibilities. He died at Cambridge, Mass., on April 2, 1928.

(R. E. O.; X.)

RICHARDSON, DOROTHY MILLER (1873–1957), English pioneer in stream-of-consciousness fiction, was born in Abingdon, Berkshire, on May 17, 1873, and passed her childhood and youth in secluded surroundings in late-Victorian England. After her schooling, which ended when, in her 17th year, her home broke up, she engaged in teaching, clerical work and journalism. In 1917 she married the artist Alan Elsden Odle (1888–1948). She commands attention for her sequence novel *Pilgrimage* (published in separate volumes—she preferred to call them chapters—as *Pointed Roofs*, 1915; *Backwater*, 1916; *Honeycomb*, 1917; *The Tunnel*, 1919; *Interim*, 1919; *Deadlock*, 1921; *Revolving Lights*, 1923; *The Trap*, 1925; *Oberland*, 1927; *Dawn's Left Hand*, 1931; *Clear Horizon*, 1935; the last part, *Dimple Hill*, appeared under the collective title, four volumes, 1938). She died June 17, 1957, at Beckenham, Kent.

Pilgrimage is the extraordinarily sensitive story, seen cinematically through her eyes, of Miriam Henderson, an attractive, spinsterish and mystical New Woman. Unfortunately, she is more new than woman, since, for a character committed to the stream-of-consciousness technique of self-revelation, her reactions to her various experiences are selected and edited with peculiarly improper reticence; while hers is entirely a woman's consciousness, it is not nearly a woman's entire consciousness. Moreover, the author too often lavishes her surpassingly delicate perceptiveness upon dull material. Nevertheless, no student of fiction can afford to overlook *Pilgrimage*, one of the significant novels of the 20th century.

See J. C. Powys, *Dorothy M. Richardson* (1931); Caesar R. Blake, *Dorothy Richardson* (1960). (J. Pt.)

RICHARDSON, HENRY HANDEL (pseudonym of Ethel Florence Lindesay Richardson Robertson) (1870–1946), considered by some to be Australia's greatest novelist. Born at East Melbourne, Victoria, Jan. 3, 1870, she was educated at the Presbyterian Ladies' college, Melbourne, and in 1887 she went to Leipzig to study music. She was influenced by continental rather than English literature and thought, and apart from a short visit in 1912 to obtain material for her work, she did not return to Australia. In 1895 she married J. G. Robertson, who was appointed in 1903 to the chair of German literature in the University of London. Her first novel, *Maurice Guest* (1908), was based on her experiences in Leipzig and like much of her work was partly autobiographical. *The Fortunes of Richard Mahoney* (*Australia Felix*, 1917; *The Way Home*, 1925; *Ultima Thule*, 1929) is the story of an Irish immigrant who bears a strong resemblance to her father. Other works published during her life were: *Two Studies* (1931); *The End of a Childhood* (1934); *The Young Cosima* (1939).

She died at Hastings, Sussex, March 20, 1946, leaving an unfinished autobiography, *Myself When Young*, published in 1948.

Bibliography.—N. Palmer, *Henry Handel Richardson: a Study* (1950); L. J. Gibson, *Henry Handel Richardson and Some of Her Sources* (1954); E. Purdie and O. Roncoroni, *Henry Handel Richardson: Some Personal Impressions* (1958). (C. M. H. C.)

RICHARDSON, HENRY HOBSON (1838–1886), U.S. architect, was both the initiator of the Romanesque revival and a pioneer figure in the development of an indigenous, modern American style. He was born on Sept. 29, 1838, in St. James parish, La. After graduating from Harvard college in 1859, he studied architecture at the École des Beaux-Arts, Paris, returning to the United States in 1865. Shunning the neoclassical traditions in which he had been trained, Richardson experimented briefly with Victorian Gothic and then turned to the French Romanesque style epitomized in his famous Trinity church of Boston (1872–77).

The Marshall Field Wholesale building, Chicago (1887; demolished 1930), was the masterpiece of the bold, original style that he gradually evolved: characterized by an unornamented exterior and rows of tall, arched windows, it relied for effect upon its lines and the skillful handling of material. This style survives in his Ames-Pray building, Boston. Among his other notable works are the Pittsburgh courthouse and jail; the capitol at Albany, N.Y.; Sever hall, Harvard university; and many distinctive, shingled country houses such as Stoughton house, Cambridge, Mass. His Romanesque had an integrity and grace seldom achieved by his many imitators in the latter half of the 19th century; his modern style presaged the revolutionary work of Louis Sullivan (*q.v.*). Richardson died on April 27, 1886, in Boston.

See Henry Russell Hitchcock, *The Architecture of H. H. Richardson and His Times* (1936).

RICHARDSON, JOHN (1796–1852), Canadian novelist, whose most valuable works are autobiographical and historical, was born at Queenston, near Niagara Falls, on Oct. 4, 1796. During the War of 1812, Richardson, a gentleman volunteer, was taken prisoner at Moraviantown, where Tecumseh was killed. Released in 1815, Richardson served as a British officer in England, Barbados, and Spain. *Écarté* (1829), a novel of the salons of Paris, and *Kensington Gardens in 1830*, a satire in verse, reflect his gay life abroad. Drawing upon his experiences in Canada, he published *Tecumseh* (1828), a metrical romance, and *Wacousta* (1832), an exciting novel about the Pontiac conspiracy. Several minor books recorded Richardson's disagreement with Lieut. Gen. De Lacy Evans, his commanding officer in Spain.

Returning to Canada in 1838, he edited *The New Era* (1841–42) in Brockville and published *The Canadian Brothers* (1840), a sequel to *Wacousta; War of 1812* (1842), a historical account; and *Eight Years in Canada* (1847), an autobiography. Attracted by the American market for inexpensive editions of his works, including *The Monk Knight of St. John* (1850), *Hardscrabble* (1850), and *Wau-nan-gee* (1852), he spent his last years in New York, where he died on May 12, 1852.

See A. C. Casselman, *Richardson's War of 1812* (1902); W. R. Riddell, *John Richardson* (1923). (C. F. Kk.)

RICHARDSON, LEWIS FRY (1881–1953), British pioneer in the application of mathematics to weather forecasting, was born at Newcastle upon Tyne on Oct. 11, 1881, of an old Quaker family of tanners. He was educated at Bootham School, York, and at King's College, Cambridge. His mathematical work, marked by great originality of thought, mainly concerned the calculus of finite differences, the prediction of weather by computation, the study of diffusion, and, later, the use of mathematics to elucidate the causes of war (speculations arising from religious conviction). Richardson made major contributions to numerical methods of solving boundary-value problems in physics, and during 1913–22 applied these ideas to meteorology in a bold attempt to produce a systematic method of forecasting depending entirely on calculation. This work culminated in his classic *Weather Prediction by Numerical Process* (1922), with its scheme for "numerical" forecasting including a worked-out example. Although this example was a failure, caused partly by inadequate upper-air data and partly by the limitations of the mathematical method, the line of thought thus pioneered and the later invention of the high-speed electronic computer together made numerical forecasts practicable. In his work on diffusion Richardson was likewise ahead of his time, in that concepts that he advanced in 1926 were not fully recognized as valid until 20 years later, when they were rediscovered by others. His name is preserved in studies of convection by the "Richardson number," a fundamental quantity involving the gradients of temperature and velocity. He died at Kilmun, Argyll, on Sept. 30, 1953.

See E. Gold, *Obituary Notices of Fellows of the Royal Society*, 9 (1954); J. R. Newman (ed.), *World of Mathematics*, vol. 2 (1956). (G. Sn.)

RICHARDSON, SIR OWEN WILLANS (1879–1959), English physicist awarded the Nobel prize for physics in 1928, was one of the founders of atomic physics. He discovered the Richardson law, concerning the emission of electricity from hot

bodies, on which is based the action of wireless valves; his work on valves helped to revolutionize radio communication through the development of the hard thermionic valve. Born at Dewsbury, Yorkshire, on April 26, 1879, Richardson was educated at Trinity college, Cambridge. He was professor of physics at Princeton university, 1906–13, and at King's college, London, 1914–24, Yarrow research professor of the Royal society, director of research in physics at King's college and, from 1944, emeritus professor of physics of London university. Richardson was elected fellow of the Royal society in 1913 and was knighted in 1939. He died at Alton, Hampshire, on Feb. 15, 1959. Among other standard works he wrote *The Emission of Electricity From Hot Bodies* (1916; 2nd ed., 1921).

RICHARDSON, SAMUEL (1689–1761), English writer who created the dramatic novel in English. His detailed exploration of feelings and motives introduced a new dimension into fiction, and profoundly influenced the novel's development as an intimate record of inner experience and a means of expressing a serious criticism of life.

Life.—Little is known of Richardson's early life. The son of a London joiner, or cabinetmaker, he was born in Derbyshire in 1689, but later his family returned to London. He himself says that he had only "common school learning." Being "not fond of play" he was nicknamed "Serious" and "Gravity," but was in demand as a teller of stories, which always carried "a useful moral." He also acquired a reputation as a writer of letters. At age 10 he wrote anonymously to a widow of 50, reproving her hypocrisy and malice. He was "an early favourite with all the young women of taste and reading in the neighbourhood" and was employed to write answers to their love letters.

In 1706 he was apprenticed to the London printer John Wilde. He rose steadily, becoming a freeman of the Stationers' Company in 1715, and in 1718 or 1719 setting up his own business. In 1739 he acquired the lease of part of a house at North End, Hammersmith. This became a much-loved home, and in a "grotto," or summerhouse, in the garden, he wrote his novels and voluminous letters, and entertained his admirers, including the so-called "garden of ladies"—Sarah Fielding and her sisters, Mrs. Elizabeth Carter, Hester Chapone, Susannah Highmore, daughter of Joseph Highmore (*q.v.*), Sarah Westcomb, to whom he became an "adopted" father, Charlotte Lennox, and other "bluestockings," with whom he discussed his novels before publication. This country house was also a meeting place for other friends—Aaron Hill, Dr. Johnson, Hogarth, Colley Cibber, Arthur Onslow (the speaker of the House of Commons, who in 1724 had employed him to print its *Journals*), and Edward Young, whose *Night Thoughts* he published. In 1754 he became master of the Stationers' Company, and moved from North End to Parsons Green, where he died on July 4, 1761.

In his business career, Richardson was prosperous, respectable, hardworking, thrifty, prudent, and humdrum. His outward success concealed the impact of private tragedy. He was twice married, in 1721 to Martha Wilde (d. 1731), his master's daughter, and in 1732 to Elizabeth Leake, sister of a prosperous bookseller in Bath. Of six children of his first marriage, five died in infancy, and one, a boy of four, in 1730. Another son, born in 1739, died in 1740. These and other bereavements—11 between 1729 and 1731—helped to bring on the nervous ailments of his later life. His professional success also concealed any hint that he was to write the great tragic novel of his time.

Works.—*Pamela.*—Richardson began his first novel at the age of 51. He had acquired a reputation for writing indexes, prefaces, dedications, and abstracts; and in 1739 the booksellers Charles Rivington and John Osborn asked him to compose a collection of model letters for the use of people with little formal education. He wished to make it morally instructive, as well as useful, and when it was published (January 1741), it was entitled *Letters written to and for particular Friends, on the most Important Occasions. Directing not only the requisite Style and Forms to be observed in writing "Familiar Letters"; but how to think and act justly and prudently, in the common Concerns of Human Life.* Meanwhile, in writing letters suitable for a maidservant and her father, which would warn against masters' designs on their maids' virtue, he had remembered a real-life story about a girl whose resistance had been rewarded by marriage to her master, and had hit upon the idea of telling it in a series of letters written to her parents. So arose *Pamela, or, Virtue Rewarded*, published anonymously in November 1740. It became probably the most widely read novel of the century, going through five editions in less than a year, and being translated into French, Dutch, German, Italian, and Danish by 1750. Richardson's success was embittered, however, by attacks on its morality. Opinion in Europe became deeply divided, some regarding *Pamela* "as an example for Ladies to follow . . . . Others . . . [discovering] in it the behaviour of an hypocritical, crafty girl . . . who understands the Art of bringing a man to her lure." Outstanding among the attacks were two by Henry Fielding (*q.v.*): the parody of the *Apology for the Life of Mrs. Shamela Andrews* (1741), and *Joseph Andrews* (1742). Since Richardson brought to fiction a deeply moral purpose he was considerably stung, and he was further annoyed by the unscrupulous compilation of a sequel by the hack writer John Kelly. Having tried to prevent this, Richardson began his own continuation in two volumes (published, September 1741, as *Pamela's Conduct in High Life*), which had formed no part of his original plan, and, since it sprang from no imaginative impulse, shows him at his worst and most didactic.

Pamela's real significance lies in its dramatic and exploratory use of the letter form. The heroine is created from inside; the reader is not told about her by an all-knowing narrator, or a later self, but experiences her story through her own mind as the events occur. Writing a novel in letters has its own difficulties and clumsiness, but also great advantages. Pamela is startlingly alive, her homespun language gives immediate and complex insights into her mind, and the reader's understanding of her experience develops with hers. The form is "dramatic" because the author banishes himself and creates only through his characters, by imagining himself into their minds. It is "exploratory" because the more vividly he imagines this consciousness other than his own, the more he is led to discover in it unrealized depths. This exploration is increased when one character is set in conflict with others. Even in *Pamela*, in which the letters come almost entirely from the heroine, the conflict of values between the puritan girl and her rakish master, Mr. B., allows the reader to see Pamela as clearly through his eyes as to see him through hers, and to realize that both views are inadequate. We must never make the easy mistake of confusing Richardson with his characters. Through his dramatic exploration of his heroine's character in the carefully constructed early scenes, he came to realize weaknesses in her values, which may have been his own when he began to write. This led him to isolate her to explore the implications of his discovery. He finds a kind of blindness in her purity, a pride behind her prudence, a lack of faith in God and in man behind her guarded self-reliance. Only after 40 days and nights of imprisonment and temptation, during which she nearly succumbs to the ultimate sin of suicide, does she find that double faith; only when she finds it can she find happiness, or create the possibility of a human relationship with her tormented tormentor, struggling with his barren pride.

The novel has faults. It is often crude, sometimes comically so. Many of its attitudes, to class, to sex, to the "rewards" of virtue, especially, are limited. Richardson fails to examine his hero, or to create his development from plotting seducer thoroughly enough to make his final offer of marriage convincing. Yet the novel's significance lies in the way that its insights grow in depth, humanity, and understanding. It is not a great novel, but it is the preparation for one.

Clarissa.—Richardson had completed an outline of *Clarissa: or, the History of a Young Lady* by June 1744, but the first two volumes only appeared in November 1747. They are a powerful study of bourgeois materialism and family tyranny. The acquisitiveness of the Harlowes (Clarissa's parents), their authoritarianism, pride and cruelty, slowly enclose her in a trap from which there are only two exits: marriage to a man she despises, in obedience to their will, or elopement with the rakish Lovelace, into which she

is eventually tricked. Volumes III and IV (April 1748) explore the conflict between Clarissa's absolute moral values and the unscrupulous sex-war code of Lovelace, who uses her propriety and delicacy against her in a plan to seduce her if he can, and marry her only if he must. He tricks her into a London brothel, from which she escapes, only to be brought back as the darkest phase of the novel opens. In volumes V, VI, and VII (December 1748), Lovelace, incapable of giving up the view of men and women on which his view of life is based, his heart hardened by the urgings of the prostitutes and by his own wounded pride at his failure to win Clarissa, and obsessed with the need to satisfy that pride and impose his will, rapes Clarissa while she is under the influence of drugs. She temporarily loses her reason, her appeals to her family are rejected, and she herself rejects a Lovelace now aware of what he has done. She dies: but it is a holy death which Richardson clearly sees as a mark of divine grace, releasing her from a world in which human beings torture one another and themselves.

This novel is many things. Most significantly, perhaps, it explores the two chief forces in the world from which Richardson himself sprang. It is a sombre indictment of a life lived in terms of money and power; both the bourgeois Harlowes and the aristocratic Lovelace are opposed to deeper and truer values. It is also, however, a revealing exploration of the strength and weakness of the absolute, ultimately puritan, code of ethics to which Richardson himself subscribed. In his imaginative realization of Clarissa he brings out the implications of her passivity, her vulnerability to people less scrupulous than herself, her inability to understand evil. Yet, in tragedy and dissolution, he triumphantly vindicates her integrity, the ultimate moral and religious strength of her "holy living and dying."

Formally *Clarissa* represents a great advance on *Pamela.* Though most of the narrative is carried by Clarissa's letters, Richardson uses three further points of view to explore all the implications of the events: the consciousness of her vivacious and rebellious friend, Anna Howe; that of Lovelace; and that of his reforming friend, Belford. There is thus a continuous cross-illumination and complexity of analysis; but the reader must be constantly aware of the implications of each attitude, continually building up an understanding that is fuller, deeper, and more complex than that possessed by any character in the novel. The disadvantage is the novel's great length, as events are repeated from different points of view. Yet few who have experienced its slow inevitability and the depth of its gradually unfolding meaning count it too long. There are also letters from numerous minor characters, in all of which Richardson gave rein to his belief that "styles differ, too, as much as faces, and are indicative . . . of the mind of the writer."

Sir Charles Grandison.—The History of Sir Charles Grandison was published in 1753–54. Fielding's *Tom Jones* had achieved great success in 1749, and though there is little evidence that Richardson really knew it, and much that, if he did, he misunderstood it, it seems likely that *Grandison* was written to show what a really good man was like in contrast to Fielding's hero. Though it shows deeply felt ideals, it has only glimpses of the imaginative genius of *Clarissa.* Its hero behaves with undeviating rectitude and benevolence, in all kinds of awkward situations, including the ultimate one of a triangular relationship with two beautiful and good women, Harriet Byron and Clementina della Porretta, both of whom merit his respect. He is used to illustrate his creator's conviction that the foundation of morality is goodness of heart, and that the truest human pleasure flows from virtue and benevolence. Both ideas, ironically, are very close to Fielding's. The novel also illustrates Richardson's longing to extend the family beyond the mere accident of blood, as his men and women develop from friendship into a deeper brotherhood and sisterhood on a basis of profound moral harmony and love—so, in real life, he offered brotherhood and fatherhood to his admirers. It also shows his liberal attitude to religious differences, and his championship of a more liberal attitude to women.

With all this, however, the novel has a deadness at the core. If we find Sir Charles priggish it is because he knows little uncertainty, he is never forced into the abysses of his being as Pamela and Clarissa are. But good things remain. The lively description of Harriet Byron's first experiences of London are a reminder of Richardson's influence on Fanny Burney and Jane Austen. Into the mental conflicts of Harriet and Clementina the probing imagination of the author of *Clarissa* has entered, if not with the same sombre resonance, yet with life-giving and revealing power.

Influence.—Richardson had little permanent direct influence on English fiction. But his works played a part in the growth of the novel of sentiment, especially on the continent. Diderot eulogized him, Rousseau adapted him, and a whole series of German writers admired his emotional power. Yet this kind of influence misses his real strength. It was indirectly through Jane Austen—though after her epistolary juvenilia she discarded the letter-form—that the legacy of Richardson's "point-of-view" writing was transmitted to later English novelists. The modern novel, after Henry James and James Joyce, if it has not turned to Richardson himself, has been largely concerned with extending and developing the type of dramatic novel he created.

BIBLIOGRAPHY.—The standard edition of the novels is the Shakespeare Head edition, 19 vol. (1930–31). The *Familiar Letters on Important Occasions* of 1741 were ed. by B. W. Downs (1928). There are bibliographies of the works, by W. M. Sale (1936), and of critical studies (1896–1946), by F. Cordasco (1948). Scholarly studies are: A. D. McKillop, *Samuel Richardson, Printer and Novelist* (1936); and W. M. Sale, *Samuel Richardson: Master Printer* (1950). A useful critical introduction is R. F. Brissenden, *Richardson,* "Writers and Their Work" series (1958). A selection of Richardson's letters was ed., with a memoir based on Richardson's own manuscript memoirs, by A. L. Barbauld, 6 vol. (1801); *see* also *Selected Letters of Samuel Richardson,* ed. by J. Carroll (1964). I. P. Watt, *The Rise of the Novel* (1957), studies Richardson in the light of 18th-century society; Morris Golden, *Richardson's Characters* (1963), studies the works more psychologically. (M. K.-WE.)

RICHBOROUGH, a port on the Stour, in Kent, Eng., 15½ mi. N of Dover by road.

Richborough Castle is one of the most remarkable monuments of the Roman occupation of Britain. It marked the beginning of Watling Street and guarded the channel of the Wantsum, then separating the Isle of Thanet from the mainland. The site shows signs of occupation in the Early Iron Age but it only entered history with the invasion of Claudius in A.D. 43. A base, Rutupiae, was established there which was used throughout the occupation. The extant remains include the north wall of the Saxon Shore fort, possibly built by Carausius in the 3rd century, 460 ft. long and 22 ft. high. There is a cruciform platform of concrete, 126 ft. long and 82 ft. wide. It was probably a monument to the emperor Domitian. A subterranean passage runs under the foundations of the platform. In 1926 excavations revealed a double series of ditches surrounding the fortifications.

During World War I, to relieve the traffic in military stores through Dover, the old port was reestablished. The Stour was widened and deepened, a canal cut across a bend, and 250 ac. of marsh were reclaimed. Nearly a mile of wharfage was built and equipped. The port eventually became derelict.

RICHELIEU, ARMAND EMMANUEL DU PLESSIS, DUC DE (1766–1822), French statesman, prime minister from 1815 to 1818 and from 1820 to 1821, had previously served Russia for two decades as a soldier and administrator. Born in Paris on Sept. 25, 1766, the son of Louis Antoine du Plessis, duc de Fronsac, and grandson of Louis François Armand du Plessis, duc de Richelieu and marshal of France, he was known as the comte de Chinon. After a tour of Europe (1782–85), he succeeded his grandfather at court as first gentleman of the bedchamber and became duc de Fronsac on his grandfather's death (1788). Sent on a mission to Germany and Austria in September 1790, he joined the Russian army and was at the capture of Izmail from the Turks (December 1790). Succeeding his father as duc de Richelieu (1791), he fought (1792) with the royalists under Louis Joseph de Bourbon, prince de Condé, and with the Austrians (1793–94). Visiting Russia (1795), he was appointed lieutenant colonel of the cuirassiers of St. George. In 1803 the emperor Alexander I persuaded Napoleon to remove his name from the list of proscribed persons in France. In the same year the tsar appointed Richelieu governor of Odessa,

and in 1805 he also became governor general of the whole area north of the Black Sea, between the Dniester and the Kuban rivers. In a notable administration he established schools, reorganized finances, and particularly encouraged agriculture and exports.

Richelieu went to Paris (November 1814) during the First Restoration. On Napoleon's return from Elba (March 1815) he accompanied Louis XVIII as far as Lille but joined the tsar for the campaign against Napoleon. After the Second Restoration he was persuaded to become prime minister (September 1815), with control of foreign affairs. Despite the extreme difficulties of the period (*see* FRANCE: *History*), Richelieu's achievement was considerable. The Congress of Aix-la-Chapelle (1818), which he attended, marked the culmination of his work to clear France from a crippling indemnity and to obtain the withdrawal of the army of occupation. He resigned in December 1818 and toured Italy and Germany. From this time onward he suffered the unwanted attentions of Désirée, queen of Charles XIV John of Sweden, who followed him everywhere he went. After the murder of the duc de Berry, Richelieu reluctantly became prime minister again (February 1820). A moderate, caught between the attacks of the Independents and the increasingly powerful Ultras (extreme royalists), his position soon became untenable and he resigned in December 1821. He died in Paris on May 22, 1822. A statue of him was erected in Odessa in 1828.

Richelieu's marriage with Rosalie de Rochechouart had been arranged before his tour of Europe (1782–85); on his return he discovered his bride to be deformed and left her immediately after the wedding. Nevertheless, although their relations were never more than platonic, in later years he took pleasure in her company.

RICHELIEU, ARMAND JEAN DU PLESSIS, CARDINAL AND DUC DE (1585–1642), French statesman, was the principal minister of Louis XIII for 18 years, during which he raised the monarchy to unprecedented heights of power both in the domestic and in the European field of affairs. For the background to this article *see* FRANCE: *History;* THIRTY YEARS' WAR.

BULLOZ

ARMAND JEAN RICHELIEU, DETAIL FROM A PORTRAIT PAINTED BY PHILIPPE DE CHAMPAIGNE. IN THE MUSÉE CONDÉ, CHANTILLY, FRANCE

The Rise to Power.—Richelieu was born in Paris on Sept. 9, 1585, the youngest son of François du Plessis, seigneur de Richelieu (d. 1590), and Suzanne de La Porte. His father, who belonged to the petty nobility of Poitou, had been a favourite of Henry III, on whose death he transferred his services to Henry IV. His mother came from a family of lawyers.

Nominated bishop of Luçon, in Poitou, by Henry IV late in 1606, when he was still below the canonical age, the young Armand went to Rome to obtain his dispensation from Pope Paul V and was consecrated there in April 1607. In December 1608 he arrived in his little bishopric, where he remained for nearly six years. Elected by the clergy of Poitou to the Estates-General, which met in Paris in October 1614, he there attracted the attention of the queen mother, Marie de Médicis, who was continuing to govern France for her son Louis XIII (*q.v.*) after the formal termination of her regency. Richelieu was chosen to present the final address of the clergy of France, and thereafter he remained in Paris, becoming almoner to Louis XIII's consort, Anne of Austria, in 1615. The marshal d'Ancre, favourite of the queen mother, procured Richelieu's appointment as a secretary of state on Nov. 30, 1616.

The murder of the marshal d'Ancre (April 24, 1617) was followed by the exile of Marie de Médicis to Blois. Richelieu, no longer secretary of state, went with her, leaving Louis XIII's government under the control of Charles d'Albert de Luynes (*q.v.*). As Marie's chief adviser, he sought to ingratiate himself with the government by reporting on her actions; but his protestations of loyalty were received with skepticism, and a few weeks later, when he had retired to one of his benefices in Poitou, he received orders to remain there or in his diocese. In this retirement he composed *Les Principaux Poincts de la foi de l'église catholique* (1617), in answer to Protestant propaganda. Indiscretions by Marie and her supporters led to his being exiled to Avignon (April 1618).

When Marie de Médicis escaped from Blois to the protection of the duc d'Épernon (February 1619), the government decided that Richelieu should rejoin her to moderate her attitude. The Treaty of Angoulême (April 1619), which temporarily reconciled her with the king and allowed her to reside at Angers, was negotiated by him, and he remained with her as her chief adviser. After the futile rebellion of the following year, in which he was perforce involved, he negotiated the Peace of Angers (August 1620), which saved Marie and her faction.

The death of Luynes (December 1621) made possible a *rapprochement* between Louis XIII and Marie de Médicis, who was admitted to the king's council. Richelieu furnished her with arguments and with criticisms of other ministers. She in turn promoted his interests, and on Sept. 5, 1622, he was created cardinal by Pope Gregory XV.

On April 29, 1624, Richelieu was himself admitted to Louis XIII's council. He was recognized as one of the chief (*premier*) ministers on the disgrace of the *surintendant* of the finances, Charles de La Vieuville (Aug. 13); and in subsequent letters patent Louis XIII designated him as "principal minister in our council of state."

Relations with the King.—Louis XIII had the highest concept of the royal authority and wished to reign as a great king; and in Richelieu he saw an energetic minister who would see that his decisions were respected. Initially, Louis felt a genuine friendship for the cardinal; but after a few years this affection cooled, as Louis resented the way in which Richelieu enhanced his personal authority and exercised control over all the kingdom's affairs by dealing with them himself or by entrusting them to creatures of his own. Above all, the scrupulous king's conscience was troubled by the cardinal's foreign policy and by the misery which long war and heavy taxation imposed on the people of France. There was thus the risk that someone might supplant Richelieu, and he had always to beware of intrigues woven in the king's immediate entourage—with the complicity, moreover, of members of the royal family. His pliancy in such moments of stress was the complement of his resolute and authoritarian nature. Louis XIII, meanwhile, however much he might sometimes wish for a change, never forgot that Richelieu was the only man capable of maintaining order. He therefore never consented to schemes for dismissing the cardinal. The consequence was a *ministériat*, that is, a sustained period of government through the "principal minister."

Internal and Foreign Politics.—Richelieu's political objectives were clear from the beginning: to reduce all the king's subjects to obedience, and to raise the monarchy's international prestige to its due height. Thus he had on the one hand to struggle against the refractory nobility and against the Huguenots (*q.v.*) in France; and on the other to intervene in the Thirty Years' War in order to prevent the Habsburgs from winning supremacy throughout Europe. The imperial line of the Habsburgs was ruling Austria, the lands of the Bohemian crown, and Alsace, apart from its theoretical suzerainty over Germany, while the Spanish line ruled the whole Iberian Peninsula, the southern Netherlands, Franche-Comté, Milan, Naples, Sicily, and Sardinia, as well as the Central and South American colonies.

Order within the kingdom was a prerequisite for action abroad. Circumstances, however, did not favour the immediate application

of a program of thoroughgoing reforms, and once the major war started (from 1635) new disorders ensued within the kingdom. Thus Richelieu's domestic and foreign policy must be considered together.

At the Assembly of Notables of 1626–27 Richelieu presented a program of reforms which he had planned as early as 1625. This comprised the cleansing of the financial system, measures to revive the economy and overseas trade, the destruction of the private strongholds owned by the nobility, the prohibition of dueling and blasphemy, and the reorganization both of teaching and of the Catholic Church in France. If this program was to be implemented, peace was necessary, at least temporarily; and this necessity explains the shortlived settlement with the Huguenots (February 1626) and the Treaty of Monzón with Spain on the question of the Valtellina (May).

Richelieu had also tried to reach agreement with England through the marriage of Louis XIII's sister, Henrietta Maria, to Charles I (1625). But just as the French supported the English Catholics, so did the English support the Huguenots; and the latter's main stronghold in France was the seaport of La Rochelle. Richelieu, moreover, as "grand master, head, and superintendent of the commerce and navigation of France" (from 1627), was determined to uphold the king's power at sea and to protect the coasts of France. So it was not for religious reasons but on grounds of general policy that he undertook the great enterprise of 1627–28 against La Rochelle, which had abetted an English attack on the Île de Ré and was expecting help from the English Navy. After the fall of La Rochelle, a campaign against the Huguenot rebels in Languedoc led to the Peace of Alès (1629), which put an end to the political and military privileges of French Protestantism.

Richelieu's action against the Huguenots encouraged the *parti dévot*, or pious Catholic faction, headed by the keeper of the seals, Michel de Marillac, to believe that he would favour an alliance between the Catholic Powers of Europe, but in fact he had little faith in friendship with Spain. After the reduction of La Rochelle, when the *dévots* stood for retrenchment and peace, Richelieu advocated an active foreign policy for which he was ready to sacrifice "all thought of repose, of thrift, and of adjustment within the kingdom." Consequently, while he was ruthless toward nobles who conspired or broke the law, as in the case of Henri de Talleyrand, marquis de Chalais (*see* CHEVREUSE, MARIE DE ROHAN-MONTBAZON, Duchesse de), or François de Montmorency, comte de Boutteville (*see* DUEL), he had also to use force of arms to suppress the revolts of peasants and townsmen against new taxes.

Richelieu did not entertain any impracticable designs for territorial aggrandizement, such as the pushing of the French frontier to the Rhine. He wanted, however, to occupy strategic points which would hinder the movement of the Spanish and imperial armies and make their junction more difficult—the so-called "policy of gateways." He was thus interested above all in Italy, taking advantage of the War of the Mantuan Succession (1628–31) to establish French garrisons at Pinerolo (on Savoyard territory) and at Casale (*see* MONTFERRAT). At the Diet of Regensburg, moreover, in 1630, French diplomats worked to weaken the authority of the Holy Roman emperor Ferdinand II in Germany and to procure the dismissal of Wallenstein, who had led the imperial army to great success against the Protestant princes.

It was during this period, toward the end of the Diet of Regensburg, that Richelieu was most in danger of falling from Louis XIII's favour. Marie de Médicis had come to terms with the keeper of the seals and his brother, the marshal Louis de Marillac; and they almost succeeded in procuring the cardinal's disgrace. Richelieu discovered their intentions and tried in vain to justify himself. He finally despaired and was on the point of retiring when the king decided to uphold him as his principal minister. This crisis (Nov. 10–12, 1630) is known as the Day of Dupes. Michel de Marillac was dismissed from office, and Louis de Marillac was accused of peculation and beheaded after an iniquitous trial. The cardinal was created duc de Richelieu and a peer of France (August 1631), and obtained the rights to a personal bodyguard.

Marie de Médicis in July 1631 fled to the Spanish Netherlands to join her younger son, Gaston, duc d'Orléans (*q.v.*), who was heir presumptive to the throne in view of the king's childlessness. In 1632 the governor of Languedoc, Henri de Montmorency, put himself at the head of a revolt against taxation, and Gaston led an army to support him. Taken prisoner at Castelnaudary, Montmorency was tried and beheaded at Toulouse.

Richelieu continued to make the influence of France felt in the affairs of Europe. When Germany, devastated by ravaging armies, was ready for peace, Richelieu kept the war going because its continuance was the only means of ensuring that the House of Austria would not establish its supremacy in the Empire (*see* again THIRTY YEARS' WAR). He made the Treaty of Bärwalde with Gustavus II Adolphus of Sweden (1631), began obscure negotiations with Wallenstein, and after the death of Gustavus (1632), provided French subsidies for the upkeep of the Swedish armies in Germany and for Bernhard of Saxe-Weimar. After the imperial victory at Nördlingen (1634), however, the electors John George I of Saxony and George William of Brandenburg came to terms with the emperor under the Peace of Prague (1635). Then Richelieu, whose hand was strengthened by France's alliances with the United Province of Netherlands and with several Italian princes, passed to the declaration of open war against Spain (May 1635). Hostilities in Germany were already in progress before the emperor Ferdinand II retaliated by declaring war on France (1636).

Richelieu had some unequivocally devoted collaborators: for example, Father Joseph, the chancellor Pierre Séguier (*qq.v.*), François Sublet de Noyers, Michel Le Tellier, and the comte de Chavigny (Léon Bouthillier; *see* BOUTHILLIER). With their help he managed to obtain from different social groups things which they had had no intention of giving him—above all, money for the war. The assembly of the clergy, manipulated by subservient bishops, voted subsidies; the *bourgeoisie* bought administrative or judiciary offices, the number of which was increased; the nobility became accustomed to serving with more regularity in the army; the ordinary people submitted, for the most part, to heavier taxation; and the tax farmers, who enriched themselves in the process, always contrived to find the necessary money. The most dangerous of the popular risings was that of the *Va-nu-pieds* in Normandy (1639), which was put down with the help of foreign mercenaries. Generals who failed were liable to be punished, as in the case of the duc de La Valette (Bernard de Nogaret) after his defeat at Fuenterrabia in 1638. While the right of remonstrance of the *parlements* was restricted, extraordinary judicial commissions were instituted to force recalcitrants to obedience. Even so, there were conspiracies against Richelieu till the end: for example, that of Louis de Bourbon, comte de Soissons, in 1641, and that of Cinq-Mars (*q.v.*) in 1642.

It is difficult to say whether fear or apathy did more to subdue public opinion, or rather public opinions, into accepting the cardinal's regime. Richelieu was clever enough at whipping up enthusiasm for his policy by hiring propagandists or by granting special protection to journalists, such as Théophraste Renaudot (*q.v.*), founder of the *Gazette*. The splendour with which he surrounded himself and his accumulation of honours and enormously lucrative offices made a gross contrast with the misery of the people but did much to raise his personal prestige; he built the Palais Cardinal (later the Palais Royal) for himself in Paris, transformed his family's house at Richelieu into a magnificent château, and also bought a great suburban house at Rueil. Lastly, he did not extinguish all hope of reform in the kingdom, but simply postponed such reform till the return of peace.

Economic and Overseas Affairs.—Richelieu always encouraged profitable investments in overseas trade. He believed that France's products could compete advantageously with those of other countries and that a proper exploitation of resources should make France self-sufficient—able to export much and needing few imports. He encouraged the manufacture of tapestry and glassware, the plush and silk industries of Tours, the cloth of Normandy and Berry, the linen of Normandy and Maine.

Irked by the fact that overseas trade was at first virtually monopolized by the Dutch, Richelieu made great efforts to bring it into French hands; to French shipowners he sold well-found mer-

chant vessels which could be armed in time of war; and he granted privileges to companies which established colonies on the American mainland and in the West Indies. Samuel de Champlain (*q.v.*) set up permanent French posts in Canada; and Richelieu favoured this colony especially because he thought that the fur trade, carried on by barter, would not involve the dispatch of any money from France and that the conversion of the Indians to Catholicism by French missionaries would redound to the king's glory. The companies did not all prosper, as the Breton and Norman shipowners looked askance at monopolies. The Compagnie de Saint-Christophe, however, was successful in the Antilles, bringing artisans and labourers to populate the islands and eventually becoming the Compagnie des Îles d'Amérique, with exclusive rights of trading and sovereign powers. Other companies reached the region of the Amazon, the Cape Verde Islands, Senegal, and even Madagascar, where Port-Dauphin was founded.

Treaties were concluded with the Barbary States and with Morocco. At first hesitant about the Mediterranean trade, which he regarded as confined to expensive luxury goods, Richelieu became interested in it when he saw how French wood and hemp could be exported and exotic produce obtained for consumption in France or for sale along the Italian coasts, payment being made in Spanish doubloons. Wartime taxation, however, diminished the purchasing power of the French consumer, without which this trade could not be conducted regularly or profitably; and only a small number of capitalists were rich enough to make the prerequisite investments. The war, though it was ruinous to the country as a whole, helped individuals to make great profits, especially men who were already rich. Meanwhile the cardinal's interest in the navy led to victories on the high seas and to successful operations in the Mediterranean.

Intellectual and Cultural Interests.—From 1622 Richelieu was provisor, that is to say, official protector, of the Sorbonne (the chapel of which he reconstructed in the style of the churches in Rome). In matters of teaching, he wanted to develop a spirit of friendly rivalry between the universities and the Jesuits. He was unwilling to see any great extension in the study of law, lest it should increase the number of lawyers in a nation already overly addicted to litigation. On the other hand he was glad to see the upper classes concerning themselves with literature and the fine arts, and he enjoyed listening to the debates of experts on aesthetic questions. His incorporation of the Académie Française by royal letters patent (1635) bears witness to his belief that the prestige of the intellect would contribute to the glory of the reign. France's achievement in the intellectual field during his regime owed very much to his personal benevolence.

Conclusions.—Foreign affairs, his chief concern, in fact prevented Richelieu from giving effect to the far-reaching reforms outlined in his *Testament politique;* and in any case he was gifted more with the broad vision of statesmanship than with any talent for administrative detail. First and last in his political thinking was the "reason of state," which required above all that the state should be powerful internationally. For internal affairs, so long as circumstances did not allow any radical reorganization, empirical methods sufficed. This explains his recourse to the employment of commissioners, sometimes with the title of intendant (*q.v.*), who were sent into the provinces to supervise local officials, to impose new taxes, and, so far as possible, to maintain order, but who could be recalled at the king's pleasure. While the war lasted, men counted for more than institutions, though Richelieu was well aware that the authority and the efficiency of institutions ought to be enhanced.

Richelieu's regime transformed France from a state medieval in many respects into a more modern one, with a discipline overriding the concurrent interests of the various social elements. When he died, worn out by overwork, in the Palais Cardinal on Dec. 4, 1642, his death was greeted as a relief by the people; but it made no difference to events in the long run, since Jules Mazarin (*q.v.*) was eventually able to bring his work to completion. Though Richelieu died before victory had been won in his war, the king's armies were occupying important towns in the Spanish Netherlands, had overrun Lorraine and Alsace, and, on the farther bank of the Rhine, were in possession of Breisach, while on the southwestern frontier Roussillon had been conquered and Catalonia, in revolt against Spanish rule, had put itself under Louis XIII's protection. France had never before been so powerful or so much feared in Europe.

Writings.—Richelieu's letters, diplomatic instructions, and state papers are edited by the vicomte G. d'Avenel in eight volumes (1853–77). Of his *Mémoires,* the best edition is that by the Société de l'Histoire de France, in ten volumes (1908–31), covering the years 1600–29; but the editions in the Petitot and Michaud-Poujoulat collections (ten volumes [1823] and three volumes [1837–38] respectively) supply also the text for the years 1630–38. The *Testament politique,* which reflects Richelieu's thought even though the authenticity of the whole is open to question (since the manuscript is lost), first appeared in 1688 and is best edited by L. André (1947).

(V. L. T.)

RICHEPIN, JEAN (1849–1926), French writer in the tradition of Villon and the poets of low life. Born at Médéa, Algeria, Feb. 4, 1849, the son of an army doctor, he left the École Normale early and during the Franco-German War joined the *francs-tireurs.* He worked as a sailor, an actor, and a docker before his first book of poems, *La Chanson des gueux* (1876), won him both instantaneous fame and a month's imprisonment for its immorality. When Zola revolutionized the French novel by introducing Naturalism, Richepin did the same for poetry in *Les Caresses* (1877), *Les Blasphèmes* (1884), and *La Mer* (1886). He wrote novels himself: *Les Morts bizarres* (1876), *La Glu* (1881), and *Miarka* (1883); besides very successful plays: *Nana Sahib* (1883), in which he acted with Sarah Bernhardt, *Le Flibustier* (1888), *Par le glaive* (1892), *Les Truands* (1899), and *Le Chemineau* (1897; Eng. trans. by W. Wallace, 1910), a lyric drama with music by Xavier Leroux. To be properly appreciated he should be considered in his period, when thinkers were preoccupied with materialism and "scientism" as expounded by Ernst Haeckel and Ludwig Büchner. *Les Blasphèmes* translates this philosophy into verse of great power, and it has been said that Richepin's very defiance of God was almost a tribute to him. He was director of the Académie Française (to which he was elected in 1908) when he died in Paris on Dec. 11, 1926.

(R. DL.)

RICHET, CHARLES (ROBERT) (1850–1935), French physiologist, who was awarded the Nobel Prize for Medicine in 1913 for his work on anaphylaxis (hypersensitive reaction of the body to foreign proteins; *see* ALLERGY AND ANAPHYLAXIS), was born in Paris on Aug. 26, 1850. Richet received his medical degree in 1877, but before this he had carried out important researches on the role of conditioned reflexes in the digestive process and had discovered that the acid of gastric juice is hydrochloric acid. In 1881 he was appointed codirector of the *Revue Scientifique* and in 1887 became professor of physiology at the University of Paris. He worked on the physiology of respiration, on epilepsy, on the regulation of body heat, and on the treatment of tuberculosis by feeding with raw meat. Most important were

his researches on immunity and serum therapy. His studies of anaphylaxis (the term is Richet's) threw new light on such conditions as hay fever and asthma and on drug reactions and serum sickness, and explained mysterious cases of intoxication and sudden death.

Richet was a man of many interests. He was distinguished not only as a physiologist but also as a bacteriologist, pathologist, psychologist, and medical statistician, and he won further fame as a pioneer of aviation, an earnest worker on behalf of peace, a scientific investigator of occult phenomena, and as a poet, novelist, and playwright. He died in Paris on Dec. 4, 1935.

(W. J. Bp.; X.)

RICHFIELD, a village of Hennepin county in southeastern Minnesota, U.S., is located immediately south of Minneapolis. It experienced rapid growth after 1940, its population increasing from less than 7,000 to more than 40,000 by 1960. (For comparative population figures *see* table in MINNESOTA: *Population.*)

Originally called Harmony and Richland, it was renamed in 1858 when the early residents of the area held their first town meeting in a schoolhouse near Richfield Mills. It was incorporated as a village in 1908; in 1950 it adopted a village-manager form of government.

Although mainly a residential suburb of Minneapolis, it has several small light-industrial establishments that manufacture metal and wood products. Agriculture was once the dominant industry and, while its importance has diminished in the economy of the community, there is still significant dairying and truck farming of small vegetables, fruits and berries. (R. W. F.)

RICHLAND, a planned city and atomic-industry town in Benton County, Wash., U.S., is located near the confluence of the Yakima and Columbia rivers about 50 mi. W of Walla Walla. Once it was the home of the Wanapam, or Wanapum, Indians, a division of the Sahaptin stock. Nelson Rich, builder of a local irrigation system, laid out a town there in 1892; incorporated in 1910, its population of about 250 remained virtually static until the site became part of the 400,000-ac. reservation of the Hanford atomic energy plant.

Its population was 1,415 by 1944, grew to 13,453 the next year, and rose to 23,548 by 1960. (For comparative population figures *see* table in WASHINGTON: *Population.*)

First administered by the U.S. army corps of engineers and E. I. du Pont de Nemours & Co., the Atomic Energy Commission and the General Electric Company took over on Jan. 1, 1947. Transfer of real estate to its residents began in 1957, and in 1958 it became incorporated as a city with a council-manager form of government. (H. J. De.)

RICHMOND, EARLS AND DUKES OF. The English title earl of Richmond appears to have been in existence for some time before it was held in accordance with any strict legal principle. Until the end of the 14th century it was usually held by counts or dukes of Brittany or by claimants to the duchy, and the honour (territory) was at first called the honour of Brittany. EUDON (d. 1079), younger brother of Alan III (d. 1040), duke of Brittany, at first disputed the ducal title with Alan and with Alan's successor Conan II (d. 1066), but was eventually satisfied with a partition of the family lands and the style of "count of Brittany." Eudon's third son ALAN I (d. 1089), the Red, accompanied William the Conqueror to England (1066) and a few years later was granted the Yorkshire lands formerly belonging to Edwin, earl of Mercia. He built a castle at Richmond. Alan died unmarried and was succeeded in turn by two of his brothers, ALAN II (d. 1093), the Black, and STEPHEN (d. 1135–36), Eudon's youngest son. Stephen also succeeded his eldest brother Geoffrey Boterel (d. 1093) or Geoffrey's son Conan (d. 1098) as count of Brittany. Stephen's second son ALAN III (d. 1146), the Black, the first to be formally styled earl of Richmond, fought for King Stephen at the Battle of Lincoln (1141). His wife Bertha was daughter and heiress of Duke Conan III, and their son CONAN (d. 1171) became duke of Brittany as Conan IV as well as earl of Richmond. He married Margaret, sister of Malcolm IV of Scotland. Conan IV left no sons and Brittany and the honour of Richmond passed to his daughter Constance (d. 1201). Her first husband GEOFFREY (d. 1186), a son of Henry II of England, was recognized as duke of Brittany and earl of Richmond in the year of their marriage (1181). RANULF DE BLUNDEVILLE (d. 1232), earl of Chester, second husband of Constance, also assumed the style of duke of Brittany and earl of Richmond. His marriage was annulled (1199). Constance's third husband Guy de Thouars administered the honour after his wife's death, without, however, obtaining the title.

ARTHUR I (1187–1203; *q.v.*), duke of Brittany, son of Constance and Geoffrey, was styled earl of Richmond during his mother's lifetime. He disappeared in 1203 (probably murdered by his uncle, King John) and his sister Eleanor died in prison in England, unmarried, in 1241. Meanwhile Peter, count of Dreux (Pierre Mauclerc), husband of Alix (daughter of Constance and Guy), established himself as duke of Brittany. He was granted seisin of the Richmond lands by Henry III in 1219, but the grant was revoked in 1235 when he renounced his allegiance to the English king. In 1240 Henry III gave the honour of Richmond to his wife's uncle, PETER OF SAVOY (d. 1268; *q.v.*), and he was popularly styled earl of Richmond. On Peter's death any title he may have held reverted to the crown. The earldom of Richmond was then (1268) granted to JOHN I (1216–85), duke of Brittany, eldest son of Alix and Peter. John I, however, soon surrendered the earldom to his son JOHN II (1239–1305), duke of Brittany, who accompanied the future Edward I on crusade (1270–74) and fought in the Welsh wars in 1277. His eldest son Arthur II (d. 1312) succeeded him in Brittany; his second son JOHN (*c.* 1266–1334) fought in Edward I's Scottish wars and was granted the earldom of Richmond in 1306. He died unmarried and his nephew JOHN III (1286–1341), duke of Brittany, son of Duke Arthur II, successfully claimed the honour of Richmond and was summoned to Parliament as earl in 1335. Although on friendly terms with Edward III he fought in the French Army in the early engagements of the Hundred Years' War. He left no legitimate issue and in Brittany the succession was disputed between his half-brother JOHN (1293–1345), count of Montfort-l'Amaury, and his niece's husband Charles of Blois. John of Montfort was supported by Edward III who made him earl of Richmond. But after John's capture at Nantes (1341), Edward gave the earldom (1342) to his son JOHN OF GAUNT (1340–99), afterward duke of Lancaster (*see* LANCASTER, JOHN OF GAUNT, Duke of). Gaunt surrendered the earldom in 1372 and it was restored to JOHN IV (*c.* 1339–99; *q.v.*), John de Montfort's son, who was recognized as duke of Brittany in 1365. On the death of John IV the earldom was seized by the crown and was not again held by a duke of Brittany. The Richmond lands (but not the title) were granted in October 1399 to Ralph Neville (d. 1425), earl of Westmorland, and on his death passed by a reversionary grant to JOHN (1389–1435), duke of Bedford, third son of Henry IV, who had been created earl of Richmond in 1414. Bedford died without heirs and all his honours became extinct.

EDMUND TUDOR (*c.* 1430–56), eldest son of Owen Tudor by Queen Catherine, widow of Henry V, was created earl of Richmond by his half brother Henry VI in 1452. He married Margaret Beaufort, heiress of John Beaufort, duke of Somerset. Their son HENRY TUDOR (1457–1509) was deprived of the title and lands on the accession of Edward IV in 1461 and after 1471 was in exile in France. He returned to England in 1485, defeated Richard III at the Battle of Bosworth, and became King Henry VII. The earldom of Richmond was thus merged in the crown.

HENRY FITZROY (1519–36), illegitimate son of Henry VIII by Elizabeth Blount, was created duke of Richmond in 1525. He left no successor and the title was not granted again until the 17th century. LUDOVIC STEWART (1574–1624), duke of Lennox in the peerage of Scotland, was created earl (1613) and duke (1623) of Richmond by James I. On his death without legitimate issue, his English honours became extinct but his Scottish titles passed to his brother Esmé, who was already earl of March in the peerage of England (*see* LENNOX, EARLS AND DUKES OF; MARCH, EARLS OF). Esmé's son, JAMES STEWART (1612–55), created duke of Richmond in 1641, supported Charles I during the Civil War and was in charge of the king's funeral in 1649. His son ESMÉ (1649–60) died while still a child, and most of his dignities, including the

dukedom of Richmond, passed to his cousin CHARLES STEWART (1639–72), a gentleman of the bedchamber to Charles II, whose wife Frances Teresa was a celebrated beauty at the same court. On his death without heirs the titles became extinct.

CHARLES LENNOX (1672–1723), illegitimate son of Charles II by Louise de Kéroualle, was created duke of Richmond in 1675. He was aide-de-camp to William III from 1693 to 1702 and lord of the bedchamber to George I from 1714 to 1723. His son CHARLES LENNOX (1701–50), the 2nd duke, held household appointments under George I and George II and fought at Dettingen (1743) and against the Jacobites (1745). On the death of his grandmother Louise de Kéroualle in 1734, he inherited the title of duc d'Aubigny in France. The 2nd duke's daughter, Lady Caroline, married (1744) Henry Fox, afterward Baron Holland, and became the mother of the statesman Charles James Fox. Another daughter, Lady Sarah, became, by her second husband George Napier, mother of the generals Sir Charles and Sir William Napier. Lennox' son CHARLES (1735–1806), the 3rd duke, was secretary of state for the southern department (May–July 1766) and master general of the ordnance with a seat in the cabinet (March 1782–April 1783, December 1783–February 1795). An ardent advocate of reform, he steadily opposed the war against the American colonists, favoured relief measures for Ireland, and in 1780 introduced a bill proposing annual parliaments and manhood suffrage. His "Letter . . . to lieutenant-Colonel Sharman of the Irish Volunteers," first published in 1783, became almost a manifesto of the reforming societies of the time.

The 3rd duke was succeeded by his nephew CHARLES (1764–1819), who had an army career, was a Tory M.P., and in 1818 became governor general of Canada. His son CHARLES (1791–1860) fought in the Peninsular War. As a member of the House of Lords he opposed Catholic Emancipation in the 1820s and in the 1840s opposed Sir Robert Peel's free trade policy. On succeeding in 1836 to the estates of his mother's brother George Gordon, 5th duke of Gordon, he took the name Gordon-Lennox by royal licence. His son CHARLES HENRY GORDON-LENNOX (1818–1903), 6th duke of Richmond, led the Conservative peers from 1870 to 1876, when he was created duke of Gordon. His son CHARLES HENRY (1845–1928) was succeeded in turn by his son CHARLES HENRY (1870–1935) and by his grandson FREDERICK CHARLES (1904–), 9th duke of Richmond.

RICHMOND, a municipal borough in the Richmond (Yorks) parliamentary division of the North Riding of Yorkshire, Eng., 45 mi. NNW of York. Pop. (1961) 5,776. It lies on the left bank of the Swale, where the valley is still narrow and steep-sided before the river emerges from the Pennines into the Vale of York.

The town is chiefly interesting because of the castle, which occupies the summit of a high cliff. The castle was founded about 1071 by Alan Rufus of Penthièvre in Brittany, who is said to have rebuilt the town on obtaining from William the Conqueror the estates of the Saxon earl Edwin, which embraced some 200 manors of Richmond and extended over nearly a third of the North Riding. This tract was called Richmondshire at that time, but the date of the creation of the shire is uncertain. William the Lion of Scotland was imprisoned in the castle in the reign of Henry II; otherwise the town owes its importance chiefly to its lords. It was a valuable possession in the Middle Ages, and was usually in royal or semiroyal hands. The whole shire reverted to the crown on the accession of Henry VII. The original castle covered an area of 5 ac., but the only portions remaining are the Norman keep, with pinnacled tower and walls 109 ft. high by 11 ft. thick, and some smaller towers.

The French name of Richmond (*Richemund*) was not traced farther back than about 1100, but it is probable that there was an earlier settlement on the site. As far as is known, the earliest charter was granted in 1145 giving the burgesses the borough of Richmond to hold for ever in fee farm at an annual rent of £29, but a charter dated 1146 shows that the burgesses enjoyed some municipal liberties at an earlier period. In 1278, a yearly fair was granted and in 1329, Edward III gave the first royal charter to the town. A charter of incorporation, under the title of aldermen and burgesses, was granted in 1576 by Queen Elizabeth I who also allowed a market each Saturday, an animal market every fortnight, and a fair each year on the vigil of Palm Sunday. In 1668, Charles II granted a charter under the title of mayor and aldermen.

This charter, though superseded later, was restored in the reign of James II, and, until the passing of the Municipal Corporations Act of 1835, was regarded as the governing charter of the borough. Although Richmond received a summons as early as 1328, it was not represented in Parliament until 1584, from which time it usually sent two members. From 1867 to 1885 one member was sent. In 1889, Richmond became the seat of a bishop suffragan in the diocese of Ripon, but the second and last bishop died in 1921.

The church of St. Mary is transitional Norman, Decorated, and Perpendicular, and is largely restored. The Church of the Holy Trinity, in the large marketplace, is ancient and was restored to use from ruins; only the nave and a detached tower remain. A curfew bell is tolled every evening and in the mornings the 'Prentice bell. The 16th-century tower of a Franciscan abbey, founded in 1258, still stands. Close to the town are the ruins of Easby Abbey, a Premonstratensian foundation of 1152, beautifully situated by the river. The remains include a Decorated gateway, an Early English chapel, and fragments of the transepts and choir of the church, with sufficient portions of the domestic buildings to enable the complete plan to be traced. In Friar's Wynd is the Theatre Royal, a Georgian theatre (1788). In Hill House lived Frances l'Anson or Janson, "the lass of Richmond Hill," to whom her future husband, Leonard MacNally, wrote the verses of the famous song.

The free grammar school existed in 1390, and was refounded in 1567, but the present building dates from 1850.

RICHMOND, a city of Contra Costa county, Calif., U.S., is situated on the eastern shore of San Francisco bay, 16 mi. NE of San Francisco via the San Francisco-Oakland bay bridge. The Richmond-San Rafael bridge connects it with Marin county.

The city, which is in the San Francisco-Oakland standard metropolitan area, experienced a phenomenal growth during World War II, and the population grew from 23,642 in 1940 to 99,545 in 1950, but with removal of wartime public housing declined to 71,854 in 1960. (For comparative population figures *see* table in CALIFORNIA: *Population*).

Development of the area dates from 1899, when the Santa Fe railway purchased a right of way to the bay shore. In 1900 Point Richmond became the western terminal of the system, and ferry service was established to San Francisco. The construction of a large oil refinery in 1902 furthered settlement. The city is an important industrial centre, and its harbour is one of the busiest on the Pacific coast. Major industries include petroleum refining, railroad shops, food processing and the manufacture of chemicals, electronic equipment, aircraft parts and plumbing fixtures.

The city was incorporated in 1905 and adopted the council-manager form of government in 1920. Richmond civic centre includes the city hall, hall of justice, a public library and an auditorium. (M. H. Mo.)

RICHMOND, a city of Indiana, U.S., is located 68 mi. E. of Indianapolis; the seat of Wayne county. Settled in 1806 by migrating North Carolina antislavery Quakers and German and Irish immigrants, Richmond has always been a centre of Quaker influence and organizations. The publications office and the general offices of the Five Years Meeting of Friends (Quakers) are located there, and the sessions of this group are regularly held in the city. Earlham college, a Quaker-controlled liberal arts coeducational institution founded in 1847 and noted for the large number of its graduates who have distinguished themselves in public life, is also located in Richmond, on a modern 120-ac. campus.

The Art association, civic theatre, symphony orchestra, Musical Arts society and Wayne County Historical museum are civic enterprises. Richmond also has several golf courses and city parks. Located in a prosperous agricultural area, early industries included grain threshers and steam engines, buggies and carriages, and lawn mowers; later industries were diversified and include automotive parts, school-bus bodies and cut-flower production. It was char-

tered as a city in 1840. For comparative population figures *see* table in INDIANA: *Population.* (WI. R.)

RICHMOND, a borough of New York city and a county of New York, U.S., the two having identical boundaries. Richmond includes all Staten Island and part or all of several smaller islands in New York harbour. It was named after the duke of Richmond, son of Charles II of England.

Indian attacks wiped out the earliest settlements. The first permanent settlement was made under Dutch authority in 1661 at Oude Dorp ("Old Town"). Three years later the British drove out the Dutch and took control. Gen. William Howe landed his forces on Staten Island in 1776, making it a base for his successful attack on Gen. George Washington's positions on Long Island and Manhattan. During the 19th century, Richmond grew more slowly than other sections of modern New York city, partly because it was cut off by water barriers and had to rely on ferries for transportation. When greater New York city was formed in 1898, Richmond county became one of its five boroughs.

Modern Richmond is linked by bridges to the mainland. It is an important shipping and manufacturing centre and an expanding residential area. In Richmond are Wagner college (Lutheran, established 1883), Notre Dame College of Staten Island, for women (Roman Catholic, established 1931), a community college, a zoo, museums, libraries, hospitals and several historic houses. There at Billopp house in 1776 Adm. Richard Howe tried to persuade representatives of the Continental congress to reconcile their differences with England. *See* also NEW YORK (CITY); STATEN ISLAND. (J. A. FR.)

RICHMOND, the capital of Virginia, U.S., and the seat of Henrico county, is located at the falls of the James river, 100 mi. S. of Washington, D.C. Its maximum elevation above sea level is 312 ft. The annual precipitation is 43 in. and the mean annual temperature is about 58° F. (about 14° C.), combining to give the city a moderate and comfortable climate. In 1960 Richmond had a population of 219,958. The standard metropolitan statistical area (SMSA), comprising the city of Richmond and Chesterfield and Henrico counties, had 408,494 inhabitants; in 1963 Hanover county was added to the SMSA resulting in an adjusted 1960 population of 436,044. For comparative population figures for the city *see* table in VIRGINIA: *Population.* Although the city lost population between 1950 and 1960, the metropolitan area made a substantial gain. Residential suburbs have grown with great speed since World War II. Despite this rapid growth, Richmond has managed to preserve a civic personality which, in its friendliness and good humour, is usually found only in much smaller communities.

History.—The first Europeans to visit the present site of Richmond were a party of 21 men led by Christopher Newport and John Smith, who sailed up the James in 1607 a short time after the founding of Jamestown. In 1637 Thomas Stegg established a trading post at the falls of the James, and in 1644, following the Indian massacre of that year, Ft. Charles was built. Indian attacks continued to harass the settlers, and in exchange for a grant of land William Byrd I undertook to maintain 50 men at Ft. Charles to protect the frontier. In 1737 William Byrd II, who had inherited a large tract of land at the falls, allowed Maj. William Mayo to lay out a town on what is now Church hill; it was incorporated by the general assembly in 1742 and in that year had a population of 250.

Richmond was the scene of the Virginia conventions of 1774 and 1775, and in 1780 was made the state capital, replacing Williamsburg. At that time the town had less than 300 buildings and when it was occupied by the British in 1781 the capitol was so humble a structure that the invaders were unable to find and destroy it. Construction of the present capitol was begun four years later.

By the beginning of the 19th century, Richmond's population had grown to 5,735, and the city was becoming a commercial and transportation centre of increasing prominence. In 1840 it was linked to Lynchburg by the James river and Kanawha canal. By 1860 there were 43 tobacco factories, several iron foundries, flour and corn mills, and establishments manufacturing carriages, textiles, nails, cutlery and paper; the census of 1860 ranked Richmond 13th among American cities in manufacturing. By that same year six railroads terminated in the city. Culturally the ante-bellum years were brightened by visits of such famous literary and stage figures as Charles Dickens, William Thackeray, Jenny Lind and Joseph Jefferson. Edgar Allan Poe edited the *Southern Literary Messenger* in Richmond from 1834 to 1837.

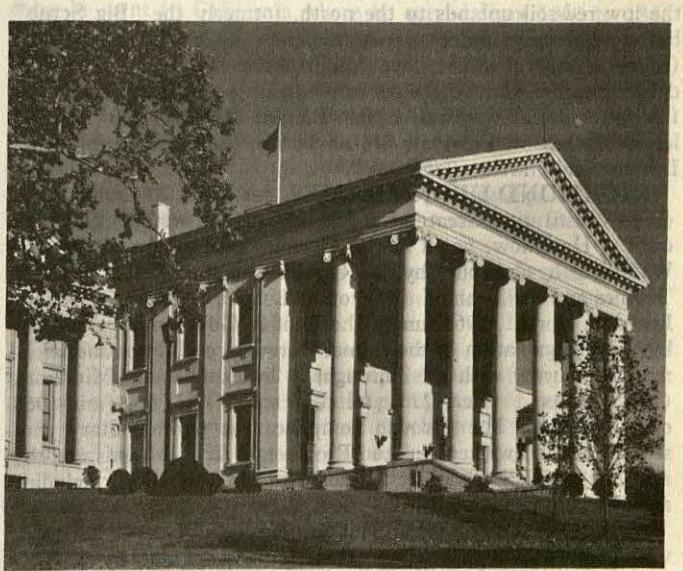
The coming of the American Civil War brought Richmond into a national and international prominence unparalleled in the city's history. Following the secession of Virginia in April 1861, the capital of the Confederacy was moved to Richmond from Montgomery, Ala. As the seat of government, and also because of its factories and railroads, Richmond was the major military objective of Union armies for four years.

In 1862 Gen. George B. McClellan's army of the Potomac was within hearing of the city's church bells but was driven away in the Seven Days' battle, June 26–July 2. Although threatened from time to time by cavalry raids, the city was not again closely beset until June 1864, when the siege of Richmond and Petersburg began. Finally, on April 2, 1865, Gen. U. S. Grant broke through the Confederate defenses, and the city was abandoned that same night, a large part of the business section being destroyed by fire in the course of the evacuation.

During the difficult postwar years Richmond was more fortunate than other southern cities in having an industry with a seemingly unlimited market: tobacco, especially cigarettes. With this as an economic base, rebuilding and recovery were soon under way. Flour mills and an iron foundry were revived; railroads were reconstructed; paper and chemical factories were established. By 1890 the population was 85,000, more than twice that of 1860. The depression of the 1930s once again demonstrated the value of the tobacco industry to the municipal economy, for Richmond suffered much less than many other U.S. cities.

Economic revival and growth were greatly stimulated by the advent of World War II. After the war, in 1948, the strong mayor type of government was discarded in favor of the council-manager system.

Historic Sites.—Richmond is pre-eminently a historic city, a fact in which its citizens have always taken great pride. The capitol was designed by Thomas Jefferson, after the Maison Carrée at Nîmes, France, and contains the famous Houdon statue of George Washington. St. John's church, where Patrick Henry delivered his "Liberty or Death" address, is still a place of worship. At the corner of 9th and Marshall streets stands the house designed, built and occupied by Chief Justice John Marshall. Reminders of the American Civil War period are numerous. Richmond is, in fact, perhaps the chief repository and guardian of the Confederate legend. The Confederate White House, the Valen-



BY COURTESY OF VIRGINIA CHAMBER OF COMMERCE, PHOTO BY FLOURNOY

THE STATE CAPITOL AT RICHMOND

tine museum, Battle abbey and the Virginia Historical society all contain books, paintings, relics and manuscripts from the war years. On Monument avenue stand large bronze statues portraying Jefferson Davis, Generals Lee, Jackson and Stuart and Comdr. Matthew Fontaine Maury. Remains of elaborate entrenchments that encircled the city can still be found in many places.

Commerce, Industry and Transportation.—In the economic life of the city, commerce is more significant than manufacturing. The chamber of commerce estimates that retail stores draw customers from 40 counties and 9 cities, including a population of over 1,000,000. The three leading components of this trade are general merchandise, food and automobiles. Richmond's wholesale market embraces most of the state plus the eastern half of North Carolina, with a sales volume twice that of retail trade. The most important products manufactured or processed in the Richmond area (ranked according to employment) are tobacco, chemicals, food, metals, paper products, printing, clothing, lumber and wood products. The presence of a federal reserve bank makes the city a financial centre for five states and the District of Columbia.

Richmond is the state's most important transportation centre and is served by several major railroads and airlines, as well as bus and truck lines. The Richmond-Petersburg turnpike allows north-south traffic to bypass both cities. At the Deepwater terminal on the James ocean-going vessels bring cargoes from the Gulf coast, Canada and elsewhere.

Education and Cultural Activities.—Richmond has a vigorous public-school system, which absorbs one-fourth of the municipal income, and a number of excellent private and parochial schools. Among the institutions of higher learning are the University of Richmond (Baptist, founded 1830), Medical College of Virginia (state-supported), Union Theological seminary (Presbyterian, founded 1812) and Virginia Union university (Baptist, established 1865).

The Mosque, a municipal auditorium seating over 4,500, is the scene of dramatic productions, as well as concerts by the Richmond Symphony orchestra and visiting orchestras. The state's finest collection of paintings and *objets d'art*, including the works of Rubens, Murillo and Reynolds, is exhibited by the Virginia Museum of Fine Arts. Library facilities include the Virginia State library and the Richmond Public library.

See also references under "Richmond" in the Index.

(L. H. J.)

RICHMOND RIVER, one of the main coastal streams of New South Wales, Austr., is usually associated with the Tweed and Clarence as the "Northern Rivers" region of the state. The three valleys form a sizable coastal lowland, in part floored by rich alluvial soils largely devoted to sugar cane. The region is also one of the leading dairying areas of Australia, especially on the low red-soil uplands to the north, formerly the "Big Scrub" but now largely under paspalum pasture. Maize (corn) and (more recently) millets are important crops associated with dairying, which (because of distance from the Sydney market) is for butter rather than raw milk. Bananas are also grown. The lower reaches of the rivers are navigable, the chief towns being Lismore and Grafton (*qq.v.*). (O. H. K. S.)

RICHMOND UPON THAMES, one of the 32 London boroughs constituting Greater London, is bounded west by the Borough of Hounslow; north by the Thames; east by the Borough of Wandsworth; and south by the Royal Borough of Kingston-upon-Thames and the Thames. This outer London borough was established on April 1, 1965, under the London Government Act 1963 by the amalgamation of the former Boroughs of Barnes and Richmond in Surrey with the Borough of Twickenham in Middlesex (*see* LONDON). Area, 22 sq.mi. (57 sq.km.). Pop. (mid-1965 est.) 181,130. The borough comprises the parliamentary constituencies of Twickenham and Richmond. It is administered by a council consisting of nine aldermen and 54 councilors, including a mayor and deputy mayor.

The area is served by the Southern Region of British Railways, with 11 stations on the line to Waterloo Station, and by the District Line of the London Underground, with two stations for the West End of London. The Chertsey arterial road traverses the borough from east to west; the most important north to south route is the road from Kew Bridge to Kingston-upon-Thames.

The borough lies on each side of the Thames and is primarily residential in character, providing homes for about 60,000 families, most of whom depend on employment in London itself.

It has a river frontage of 12 mi. (19 km.) which extends from Hammersmith to Sunbury-on-Thames in Surrey. At its nearest point it is about seven miles from Charing Cross. It is one of the most attractive suburbs in the southwest outer London area. Outstanding features are the large number of open spaces and famous buildings. Richmond Park, Bushy Park, Barnes Common, Sheen Common, Ham Fields, Marble Hill Park, and Old Deer Park are all available to the public. There are six golf courses. Twickenham, the international home of Rugby Football, lies within the borough, and the course of the Oxford and Cambridge universities boat race follows its river boundary. The Richmond Royal Horse Show is of national importance.

Famous houses, past and present, include Hampton Court Palace (the home of Henry VIII); the former Richmond Palace (used by Queen Elizabeth I); White Lodge, Richmond Park (where the Duke of Windsor was born; later, the headquarters of the Royal Ballet); Strawberry Hill (built by Horace Walpole; later a teachers' training college); Kneller Hall (built by Sir Godfrey Kneller, the painter; later the Royal Military School of Music); Marble Hill (erected by George II for the Countess of Suffolk); Orleans House (the refuge of the exiled French royal family); York House (the home of Lord Clarendon, chancellor to Charles II); and Ham House (built in 1610 and now preserved by the National Trust). The Royal Botanic Gardens at Kew are world-famous. Kew Observatory which is still in use was built in 1768 for George III.

More modern buildings are the Star and Garter Home for ex-servicemen erected on the summit of Richmond Hill to replace another famous house of the same name, and the National Physical Laboratory and Admiralty Research Laboratory, both at Teddington. There are extensive film and television studios in the borough, but no general industry of any size.

Richmond has an important shopping area which serves most of the eastern side of the borough. Smaller shopping centres are in East Sheen, Twickenham, Teddington, Hampton, and Whitton.

The greater part of the borough is influenced by its proximity to the Thames, around which it has developed. Small riverside industries are a feature of the older parts of the area, including yards for the building and repair of small craft and marine stores and accessories. There are many clubs for enthusiasts in rowing, yachting, sailing, and fishing.

There are four cinemas in the area; one professional theatre and many amateur ones; a large ice-skating rink on the riverside; and a host of clubs and societies for the benefit of those interested in drama, the arts, and other recreational and educational pursuits. The Richmond Institute of Adult Education provides a wide program of classes and the Twickenham College of Technology offers industrial and commercial courses especially for building, printing, and allied crafts. (W. H. Jo.)

RICHTER, HANS (1843–1916), German conductor who introduced the works of Wagner and Brahms into England, was born at Raab (Győr), Hungary, on April 4, 1843. He studied at the Vienna Conservatory and in 1867 was recommended by Wagner as conductor of the Munich opera, where he was associated with Hans von Bülow. In 1870 he introduced *Lohengrin* to Brussels and later conducted at Pest and Vienna. In 1876 he conducted the *Ring des Nibelungen* at Bayreuth and later became principal conductor of the Wagner festivals there. In 1877 he shared the conductorship of the Wagner festival in London with the composer and in 1882 gave the first London performances of *Die Meistersinger* and *Tristan und Isolde*. He was in charge in London of the annual Orchestral Festival Concerts (later known as the Richter Concerts) until 1897, when he became conductor of the Hallé Orchestra in Manchester. It was under his direction that this orchestra acquired its high reputation. He introduced to England many German works of the Romantic period, and also gave the first performances of Elgar's *Enigma Variations* (London, 1899), *Dream of Gerontius* (Birmingham, 1900), and First Symphony (Manchester,

1908). He last conducted at Bayreuth in 1912 and died there on Dec. 5, 1916. (E. Lr.)

RICHTER, JOHANN PAUL FRIEDRICH (1763–1825), usually called Jean Paul, the most important German humorist and, according to Stefan George, "the greatest German poetic power (although not the greatest poet)," was born in Wunsiedel, in the Fichtelgebirge, on March 21, 1763. He was the eldest of five sons of a musically gifted school teacher, who in 1765 became pastor in the village of Joditz on the Saale. There he spent an idyllic childhood, later poetically transfigured in his unfinished autobiography. In 1776 his family moved to the rather larger Schwarzenbach on the Saale where he was able to go to school more or less regularly. Eager to learn, he had access to the large library of the neighbouring pastor Erhard Friedrich Vogel, who first recognized the boy's genius. In Schwarzenbach Richter began the collection of excerpts which he continued, although in different forms, all his life, and he started to write short essays which he called "Exercises in Thinking." From 1779 to 1780 he attended the grammar school in Hof in the Vogtland, but in 1779 his father died and the family was reduced to great poverty. At Easter 1783 Richter started to study theology at the University of Leipzig, but soon gave up his studies for free-lance writing. In 1783 he found a publisher for a collection of satirical essays which he called *Grönländische Prozesse*. Soon afterward debts forced him to return to Hof, where he lived with his mother and brothers in one room, tirelessly writing witty satires, abounding in metaphors and similes, on the model of Swift and Pope, which no one would publish. It was not until 1789 that he again appeared in print, with a satirical collection, *Auswahl aus des Teufels Papieren*, which was even less successful than his first. Richter then spent several years as a private tutor in Töpen and as headmaster of a little school in Schwarzenbach (1790–94).

About 1790 the death of two intimate friends and a hallucinatory vision of his own death brought about a fundamental change in his nature, and sentiment and imagination, hitherto intentionally suppressed, broke through, bitter satire turned into sentimental humour, and Sterne replaced Swift as a model. The first product of the new period was the comic idyll *Leben des vergnügten Schulmeisterleins Maria Wuz in Auenthal*, which appeared in 1793 as an appendix to an unfinished novel in the Sterne tradition, *Die unsichtbare Loge* (English translation, *The Invisible Lodge*, 1883); as a token of admiration for Jean Jacques Rousseau, he published it under the pseudonym Jean Paul, the French form of his first two names. It was only, however, with the next work, the sentimental novel *Hesperus* (1795; English translation, 1865), that he had a decided success. He was invited by Charlotte von Kalb, the friend of Schiller and Hölderlin, to visit Weimar, where he was received warmly by Herder, and with reserve by Goethe and Schiller. Other works quickly followed, the most important *Leben des Quintus Fixlein* (1796; English translation by Thomas Carlyle, 1827) and *Ehestand, Tod und Hochzeit des Armenadvokaten Siebenkäs* (1796–97), a story of a provincial town. At the end of 1797 Richter moved to Leipzig and a year later to Weimar, where he began to write his chief work, the four-volume novel *Titan* (1800–03; English translation, 1862), in which he discusses the revolutionary ideas of the time.

During a stay in Berlin he married Caroline Mayer, the daughter of a member of the Supreme Court (1801); she bore him two daughters and one son. Richter moved with his wife to Meiningen, then, in 1803, to Coburg and, in 1804, to Bayreuth, which was his home until his death on Nov. 14, 1825. In 1804–05 he followed *Titan* with the unfinished novel *Flegeljahre* (English translation, *Walt and Vult, or the Twins*, 1846), which is at once his most "German" and his most charming work. He then published two theoretical writings, *Vorschule der Ästhetik* (1804), on poetry, and *Levana* (1807; English translation, 1848), on education. In his Bayreuth period he published several humorous works: *Des Feldpredigers Attila Schmelzle Reise nach Flätz* (1809; English translation by Carlyle, 1827), *Doktor Katzenbergers Badereise* (1809), in the manner of Tobias Smollett, and the great comic novel *Der Komet* (1820–22), which was to have been a kind of German Don Quixote but which remained a fragment. He also published several political writings inspired by the desperate situation of his country (*Friedenspredigt*, 1808; *Dämmerungen für Deutschland*, 1809; *Fastenpredigten*, 1817) as well as numerous periodical essays and reviews for the *Heidelberger Jahrbücher*, including a long one of Madame de Staël's book on Germany (1814; English translation by Carlyle, 1830). An unfinished treatise on the immortality of the soul inspired by the early death of his son was published posthumously (1827).

Longfellow called Richter "Jean Paul the Only-One" and he was indeed in many respects a unique phenomenon, hard to classify among the usual concepts of literary history. He stands between *Sturm und Drang* and *Romanticism*, but his work includes rationalist elements taken from the Enlightenment, and in certain respects it is reminiscent of Baroque writing. He united the great contrasts of humour and sentimentality, reason and imagination. His overflowing creativity often produced formlessness. He was incapable of either poetic or dramatic form, but as a prose writer he wrung from the language, to quote Stefan George, "die glühendsten Farben und die tiefsten Klänge" ("the most glowing colours and the richest music"). He had a great influence on his contemporaries, particularly on women and young men, and on later generations down to the middle of the 19th century. Then for a long time he appeared to be almost forgotten. But Ludwig Börne's prophecy that he was waiting for his public on the threshold of the 20th century was largely fulfilled.

Bibliography.—A complete edition of Jean Paul's works planned by himself appeared posthumously, 65 vol. (1826–38); historical critical edition of the Preussische (now Deutsche) Akademie der Wissenschaften directed by E. Berend, in three parts, *Werke, Nachlass, Briefe* (1927 *et seq.*). Numerous selected works and anthologies include Stefan George, *Stundenbuch für Jean Pauls Verehrer* (1900). *See* also C. Otto and E. Förster (friend and son-in-law respectively), *Wahrheit aus Jean Pauls Leben*, 8 vol. (1826–33); R. O. Spazier (nephew), *J. P. F. Richter*, 5 vol. (1833); J. Firmery, *Jean Paul* (in French, 1886); P. Nerrlich, *Jean Paul, sein Leben und seine Werke* (1889); W. Harich, *Jean Paul* (1925); J. Alt, *Jean Paul* (1925); M. Kommerell, *Jean Paul*, 2nd ed. (1939); *Denkwürdigkeiten*, ed. by E. Förster, 4 vol. (1863); E. Berend, *Jean-Paul-Bibliographie*, 2nd ed. (1963). (Ed. Be.)

RICHTHOFEN, FERDINAND PAUL WILHELM, Baron von (1833–1905), German geographer and geologist and one of the outstanding personalities during the period of reemergence of geographical studies in Germany, was born on May 5, 1833, at Karlsruhe in Silesia. He studied chemistry, physics, and geology at Breslau (now Wroclaw, Pol.) and then Berlin, where he also attended Carl Ritter's geographical lectures. Geological investigations in the Dolomites and Transylvania established his reputation and in 1860 he was invited to join, as its geologist, a German economic mission to the Far East. He visited Ceylon, Japan, Formosa, Celebes, Java, and the Philippines, and journeyed across the Malay Peninsula from Bangkok to Moulmein. From there he went to California where he stayed from 1863 to 1868 carrying out geological investigations, some of which led to the discovery of vast goldfields. In 1868 he went back to the Far East and in remarkable journeys penetrated into almost every part of China. In 1872 he returned to Germany and devoted the following years to the preparation of his work, *China, Ergebnisse eigener Reisen und darauf gegründeter Studien*, five volumes plus atlas (1877–1912), the last three volumes published posthumously. He was appointed professor of geography at Bonn in 1875 but deferred taking up his duties until 1879.

In 1883 Richthofen succeeded O. Peschel at Leipzig and in 1886 he took over the chair at Berlin and held this post until his sudden death on Oct. 6, 1905.

Von Richthofen's main achievements are his great work on China and his contributions toward the establishment of the science of geomorphology, and toward the development of geographical methodology. He was president of the Berlin Geographical Society and in 1899 he organized the Berlin International. Geographical Congress. He also founded the Berlin Institute of Oceanology.

He was honoured by the award of the founder's medal of the Royal Geographical Society in 1878, and on his 70th birthday by the establishment of the Richthofen Foundation. In his memory a Richthofen Colloquium is held annually at Bonn and the

Richthofen Medal is awarded by the Berlin Geographical Society.

The most important of his other writings are his inaugural lecture, *Aufgaben und Methoden der heutigen Geographie* (1883); *Führer für Forschungsreisende* (1886), the first systematic treatment of geomorphology; *Triebkräfte und Richtungen der Erdkunde im neunzehnten Jahrhundert* (1903), his address on the occasion of his installation as vice-chancellor. Posthumously published were: *Tagebücher aus China,* two volumes, edited by E. Tiessen (1907); *Vorlesungen über allgemeine Siedlungs- und Verkehrsgeographie,* edited by O. Schlüter (1908).

(K. A. S.)

RICIMER (Flavius Ricimer) (d. 472), patrician and "kingmaker" in the Western Roman Empire, was the son of a chief of the Suebi and of a Visigothic princess, and early became a friend of the future emperor Majorian (*q.v.*). He defeated an attempted Vandal invasion of Sicily at Agrigentum in 456, pursuing the enemy's fleet to the neighbourhood of Corsica, where he overcame it. He was appointed master of the soldiers in that year, and defeated the emperor Avitus at Placentia (Piacenza) on Oct. 17, 456, compelling him to abdicate. On Feb. 28, 457, he was appointed patrician, and, after elevating Majorian to the Western throne, he became consul in 459. But he was soon at enmity with his protégé Majorian. When the latter returned from Gaul to Italy without an army after the disastrous failure of his campaign against the Vandals, he fell into Ricimer's hands at Dertona (Tortona) on Aug. 2, 461, and was dethroned and executed on Aug. 7. On Nov. 19 Ricimer appointed Libius Severus as Western emperor at Ravenna. A dangerous rival to his power was Marcellinus, a former officer of Aetius, who had set up something like an independent state in Dalmatia. After Avitus' death a conspiracy was formed with a view to putting this Marcellinus on the throne; but it came to nothing, and Ricimer was able to keep him at a distance. Another foe was Aegidius, a general of Majorian, but he was tied down by wars against the barbarians in Gaul and died in 464. Gaiseric and the Vandals constantly raided Italy and Sicily, and on Aug. 15, 465, Libius Severus died. The Eastern emperor Leo I appointed Anthemius (*q.v.*) as emperor of the West on April 12, 467; and in the following year both emperors launched a vast expedition against Vandal Africa. It was utterly defeated, and Anthemius soon fell under Ricimer's displeasure. In April 472 Ricimer elevated Olybrius to the throne, and laid siege to Anthemius in Rome. He completely defeated his opponent's forces outside the city, and Anthemius was beheaded on July 11, 472. But Ricimer himself died on Aug. 18 and his puppet Olybrius on Nov. 2 of that year.

Ricimer was an Arian Christian, and as a barbarian he could not hope to have himself recognized as emperor. Hence his policy of elevating puppet rulers in whose name he could act. For 16 years he held the fate of Italy in his hands, apart from the time when Majorian was on the throne (for Majorian was no puppet). He was not wholly unsuccessful in defending Italy against the Vandal fleets, and he also kept under control the barbarian mercenaries on whom his power largely rested. In addition, he defended the provinces successfully against the Ostrogoths and the Alani. He was succeeded as master of the soldiers by his nephew, the Burgundian Gundobad.

(E. A. T.)

RICKENBACKER, EDWARD VERNON (1890–), U.S. airline executive, was born in Columbus, O., Oct. 8, 1890. He had little formal education but very early became interested in internal combustion engines and in engine-driven vehicles of all kinds. By the time the United States entered World War I, Rickenbacker had become famous for his reckless preoccupation with speed on the racetracks. He was one of the country's top three racing drivers and had set a world speed record of 134 m.p.h. at Daytona Beach, Fla. He went overseas as an army sergeant-driver attached to Gen. John J. Pershing's staff but quickly gravitated into aviation. He proved to be a natural fighter pilot and ended the war as America's outstanding "ace," with the rank of captain. He was awarded almost every decoration attainable.

Rickenbacker returned to the automobile industry after World War I. He headed his own company, the Rickenbacker Motor Car Company, for a time and on its dissolution joined Cadillac Motor Car Company and then its associated aviation interest, General Aviation Mfg. Co. He transferred to the airline business in 1932, first with American Airways and then with North American Aviation, Inc. On Jan. 1, 1935, he began his career with Eastern Air Lines, rising from general manager to chairman of the board of directors. Except for a period during World War II when he toured many of the combat theatres as a special representative of the U.S. secretary of war, he applied his energies to build Eastern Air Lines into one of the leading air-transport systems of the world.

(S. P. J.)

RICKETS, a disease of infancy and childhood characterized by a disturbance of the normal process of calcification of bones, with resultant deformity. It most commonly occurs toward the end of the first year and during the second year of life. The disease is caused by a deficiency of vitamin D, which is found in certain foods and is synthesized in the skin under the influence of ultraviolet light (*see* Vitamins: *Vitamin D*). Rickets is uncommon in the tropics, whose inhabitants are exposed year-round to strong sunlight; and in regions where fish is a main article of diet, as in the far north. It has become a rare disease in the United States, Canada, Western Europe, and other places where supplementary vitamin D is regularly prescribed for infants and where eggs and milk are part of most children's diet.

Factors predisposing to the development of rickets are premature birth and unusually rapid growth. Common early symptoms include restlessness and profuse sweating particularly during sleep; lack of muscle tone in the limbs and abdomen; slowness to sit, crawl, and walk; and delay in the eruption of the teeth. Softening of the bones of the skull in the first few months of life is another early sign. Enlargement of the ends of the long bones and a knobbed appearance of the ribs at their junctions with the costal cartilages, due to enlargement of the epiphyseal cartilages, are common findings. Definitive diagnosis is made by X-ray examination of the long bones, and determination of calcium and phosphorus levels in the blood.

Unless treatment is instituted early, the bones show various degrees and types of curving and deformity, the legs being more deformed than the arms so that "bow legs" or "knock knees" develop. Bending may occur in the legs before walking is begun, although with weight-bearing the bending increases. Deformity of the pelvis in the female may have the long-range effect of difficulty with childbearing. If untreated, the disease terminates in time with the hardening of the deformed bones. Complications associated with rickets include bronchitis, bronchopneumonia, gastroenteritic disturbances, muscular weakness, enlargement of the liver and spleen, and anemia. Tetany (spasms of the hands and feet, and sometimes convulsions, caused by abnormal calcium metabolism) may occur, particularly in early spring.

Rickets is treated with vitamin D in the form of concentrates, irradiated ergosterol, fish-liver oils, exposure to sunlight or ultraviolet light, or at times merely with an adequate enriched diet. The disease is observed in conjunction with, or as a complication of, other diseases such as scurvy, coeliac disease, cystinosis, paroxysmal laryngitis, and renal failure. A rare form of rickets is refractory to vitamin D therapy; the cause for this is unknown.

Osteomalacia, sometimes called adult rickets, is a progressive softening of the bones due to vitamin D deficiency in later life. The spine, pelvis, and lower limbs may become deformed. Osteomalacia occurs chiefly in the Orient. It is fairly frequent among Muslim women, who customarily remain indoors much of the time and, when they do go abroad, are completely shrouded against sunlight.

RICKETTS, LOUIS DAVIDSON (1859–1940), U.S. mining engineer who brought more of the world's great copper-mining properties into production than perhaps any other engineer, was born in Elkton, Md., on Dec. 19, 1859. He received the degrees of B.S. and doctor of science from Princeton University in 1881 and 1883, respectively, then spent seven years acquiring experience in western mining camps. He was given important assignments as consulting engineer and manager by the Phelps Dodge Corporation and the Anaconda Copper Mining Company chiefly in properties in which those firms were interested in Arizona and Mexico. Though he was consultant to many companies, his connection with the Inspiration Company, beginning in 1912, was perhaps his most important administrative post, as he became president of the firm. His specialty was the design and construction of copper-ore concentrators, smelters, and leaching plants.

He was president of the American Institute of Mining Engineers in 1916, and was designated Arizona's "most useful citizen" in 1915. He died on March 4, 1940. (E. H. R.)

RICKETTSIAE are microorganisms which resemble very small bacteria but which grow only within susceptible cells—not in cell-free culture media, as bacteria do. The rickettsiae are primarily parasites or symbiotes of arthropods—especially lice, fleas, mites, and ticks; from these hosts the rickettsiae may spread to man and domestic animals, causing serious disease. (*See* Q FEVER; TYPHUS FEVER; ROCKY MOUNTAIN SPOTTED FEVER AND OTHER SPOTTED FEVERS.)

History.—The history of the rickettsiae is intimately associated with those forms causing human disease. Epidemic typhus, one of the great plagues of mankind, was first differentiated from typhoid fever on clinical grounds in 1837. Its nature was so catastrophic that it completely dominated the field, and sporadic occurrences of other similar diseases were hardly noticed. Late in the 19th century, however, a typhuslike disease (Rocky Mountain spotted fever) was recognized in the United States and river fever (tsutsugamushi disease, or scrub typhus) was first clearly described in Japan. By 1910 association of these diseases with arthropods was being established on firm scientific grounds with the demonstration of tick transmission of spotted fever and louse transmission of typhus. Elucidation of the microbes causing these diseases began with the work of Howard Taylor Ricketts, who described the organism of spotted fever in 1906 and who, with R. M. Wilder in 1910, also described the organism of typhus fever from the blood of patients in Mexico. Confirmatory reports appeared in rapid succession, and in 1916 the typhus-fever organism was named *Rickettsia prowazekii* in honour of Ricketts and Stanislas von Prowazek, both typhus victims themselves. For a time the etiology of typhus again became clouded because of technical difficulties, isolation of spurious agents, and the discovery of nonpathogenic rickettsialike microorganisms in lice, but the relation between the louse-borne *Rickettsia prowazekii* and typhus fever was clearly settled by 1922. A louse-borne rickettsialike agent causing trench fever was discovered during World War I.

Meanwhile, productive studies continued on spotted fever in the United States; variants of spotted fever were recognized in different parts of the world; and scrub-typhus rickettsiae were isolated. In the 1920s and 1930s numerous symbiotic organisms resembling rickettsiae were found in various arthropods. The tick-transmitted agent of heartwater fever in ruminants was identified with the rickettsiae, as were several other agents from domestic animals.

A mild typhuslike disease (Brill-Zinsser disease) was first noted in 1898 in New York, later also in other eastern seaboard cities, in immigrants from typhus-afflicted areas of Europe; the disease existed under conditions precluding louse transmission. A very similar disease, for a time confused with Brill's disease, was recognized in the southern United States beginning about 1913. However, on epidemiological grounds Kenneth F. Maxcy correctly postulated in 1929 that the southern disease was harboured by rodents and transmitted by a biting arthropod. During the 1930s murine typhus, borne by rat fleas, was clearly differentiated from epidemic typhus, borne by body lice. Still, the northern cases did not seem to be explained by the distinction. Hans Zinsser then suggested that they were sporadic recrudescences of past epidemic typhus infections—a hypothesis later verified.

In the late 1930s Q fever, first recognized independently in Australia and the United States and subsequently shown to have a wide geographic distribution in man and domestic animals, yielded a new rickettsial agent, *Coxiella burnetii* (or *Rickettsia burneti*). Still another rickettsial disease, rickettsialpox, caused by *R. akari* and transmitted by mites of the house mouse, was recognized in New York City in 1946.

Morphology and Chemistry.—Rickettsiae are minute (usually under 0.5 micron in diameter), nonspore-forming, nonmotile organisms which vary in form from round to rod-shaped. They stain poorly with ordinary aniline dyes, are Gram-negative but may be seen readily under the ordinary light microscope with special stains. A cell wall from which the protoplast inside readily shrinks on drying is clearly visible under the electron microscope and, at least in typhus rickettsiae, contains an antigenic polysaccharide. Like bacteria, rickettsiae of typhus and Q fever contain both ribonucleic and deoxyribonucleic acids; purified suspensions of some, unlike small viruses, display a modest array of independent metabolic activities.

Taxonomy.—Despite a long-felt and still-growing impression among many authorities that rickettsiae are closely related to bacteria, they have been placed in a separate class (Microtatobiotes) along with the viruses. Controversy has long existed about the inclusion of numerous other pathogenic and nonpathogenic morphologically similar organisms with the rickettsiae. While there is no sound biological basis for excluding nonpathogenic rickettsialike organisms from the rickettsial group, the fact remains that the human pathogens have been subjected to the greatest study. Controversy about classification will undoubtedly persist until more adequate information is at hand on all forms to provide sound taxonomic criteria.

Biological Properties.—Most rickettsiae are peculiarly adapted to arthropods. The mite- and tick-borne forms are especially well adapted, being harmless to the vector and transmitted from one generation to the next through the egg. Spotted-fever rickettsiae from overwintering ticks must undergo a unique reactivation phenomenon to gain full virulence for mammals. The association of *R. prowazekii* with body lice, wherein the vector itself succumbs to the infection and passage through the egg does not occur, suggests less complete and possibly more recent adaptation. From the widespread occurrence of rickettsialike symbiotes in arthropods and the prominent role of arthropods in rickettsial transmission has evolved the idea that pathogenic forms may have developed originally from symbiotes accidentally introduced into the vertebrate host by biting arthropods. Man appears only as an incidental host except in epidemic typhus, and probably trench fever, where man is the only known reservoir.

Most rickettsiae pathogenic for man (except possibly *R. quin-*

Some Important Human Rickettsioses

Disease	Causative rickettsia	Main vector	Vertebrate reservoir
Typhus group			
Epidemic typhus (including Brill-Zinsser disease)	*Rickettsia prowazekii*	body louse	man
Murine typhus (endemic typhus)	*Rickettsia typhi* (*mooseri*)	rat flea	rats
Spotted fever group (selected examples)			
Rocky Mountain spotted fever	*Rickettsia rickettsii*	ticks	probably wild rodents
Fièvre boutonneuse	*Rickettsia conorii*	ticks	dogs, rodents (?)
Rickettsialpox	*Rickettsia akari*	mites	mice
Scrub typhus (tsutsugamushi disease)	*Rickettsia tsutsugamushi*	chiggerlike mites	wild rodents
Trench fever	*Rickettsia quintana*	body louse	man
Q fever	*Coxiella burnetii*	occasionally tick; mainly air, dust, contact	cattle, sheep goats, bandicoots

tana) grow only within animal cells (in intact animals, embryonated eggs, or tissue cultures), where they multiply by binary fission. There is no confirmed growth in cell-free media. Optimal growth occurs at about 35° C, lower than the body temperature of most mammalian hosts. Outside cells, most rickettsiae perish quickly unless they are preserved by freezing (−70° C) or lyophilization. Suspensions of some pathogenic rickettsiae exert a rapid toxic effect on the vascular systems of susceptible laboratory animals as well as a destructive (lytic) action on the red blood cells of certain animal species.

Rickettsial Diseases.—Most human rickettsial diseases resemble one another remarkably. Symptoms include abrupt onset of fever, lasting one to two weeks and accompanied by headache, varying degrees of mental clouding, prostration and, after a few days, a rash. Q fever, an outstanding exception, is generally mild, produces no rash but commonly presents lung infiltrations. All are naturally transmitted by some arthropod. Q fever, however, is more often contracted by contact with infected domestic animals (including carcasses) or by the inhalation of contaminated airborne particles.

During infection the organisms are disseminated throughout the body by the blood, although some proliferate also at the site of introduction to produce a small ulcer (eschar). Except for *R. quintana* and *C. burnetii*, rickettsiae causing human disease tend to proliferate in, and damage, the cells lining small blood vessels. Vascular damage in the skin is often associated with rash, hemorrhage, or necrosis.

The intracellular habitat is probably responsible for certain unusual features of rickettsial infections, for within some body cells rickettsiae seem to be protected from antibodies and other deleterious substances. Despite the appearance of circulating antibodies just preceding and during convalescence, some viable rickettsiae persist within lymphoid tissues for months and even years after apparent recovery from epidemic typhus, Rocky Mountain spotted fever, or scrub typhus. In most instances they persist there harmlessly, but sometimes recrudescence of the latent epidemic typhus infection at a later date gives rise to a relatively mild, recurrent, typhuslike illness (Brill-Zinsser disease). During recrudescences rickettsiae again circulate in the blood. Lice feeding upon such a patient may become infected and capable of transmitting fully virulent epidemic typhus.

See BACTERIA; *see* also references under "Rickettsiae" in the Index.

RICKMANSWORTH, an urban district in the South West Herts parliamentary division of Hertfordshire, Eng., lies at the confluence of the Colne, the Gade, and the Chess on the borders of Buckinghamshire and Middlesex. Pop. (1961) 28,549. Area 11.9 sq.mi. (31 sq.km.). Rickmansworth is an old market town which has grown since World War I into a large residential district spreading into the river valleys and the surrounding woodland. Stretches of water meadows and woods have been acquired by the council as part of London's greenbelt. In the long High Street are some red-brick Georgian buildings including St. Joan of Arc's Convent School and Basing House, once the home of William Penn, the founder of Pennsylvania, and now the council offices. The Royal Masonic School for Girls was built in Rickmansworth in 1928–33 and Merchant Taylors' School was built (2 mi. [3 km.] E) in 1931–33. Moor Park, to the east, is an 18th-century mansion built on the site of a house once belonging to Cardinal Wolsey. It now belongs to the council and is used as a golf clubhouse; there are three golf courses in its 400 ac. (162 ha.) of parkland.

RICKOVER, HYMAN GEORGE (1900–), U.S. naval officer who made a major contribution to the development of nuclear propulsion for ships, was born on Jan. 27, 1900, in tsarist Russia. Taken to the United States as a child, he was reared in Chicago, Ill., and graduated from the U.S. Naval Academy in 1922. After serving at sea in various types of ships he was given command of the USS "Finch," a minesweeper, in 1937. Meanwhile he studied electrical engineering at the Navy's postgraduate school and at Columbia University, and during World War II was placed in charge of the electrical division of the Navy Department's Bureau of Ships.

After the war, Rickover went to Oak Ridge, Tenn., for instruction in nuclear physics and engineering, returning to the Bureau of Ships in September 1947. It was at this time that he began to manage the Navy's nuclear propulsion program. His driving energy was an important factor in the successful development and early delivery of the world's first nuclear-powered submarine, the USS "Nautilus," which went to sea under nuclear power in January 1955. While continuing his duties with the Navy he was placed in charge of research on reactor development for the Atomic Energy Commission. In this capacity he helped to develop the experimental nuclear plant built at Shippingport, Pa., in 1956–57 to generate electric power. Rickover was promoted to the rank of rear admiral in 1953, and to vice admiral in 1959; in the latter year he received a gold medal awarded by Congress. He became a highly controversial figure because of his single-minded insistence on the development of nuclear power and because of his public criticism of U.S. educational practices. (J. B. Hn.)

RIDDLE, a word used to describe many kinds of enigmatic questions and intentionally ambiguous statements requiring an answer. In some cultures, the term includes more than it does in Western use. African riddlers regard legal aphorisms illustrated by examples as riddles; and among Middle Eastern peoples, riddles are not differentiated from some narrative forms (*e.g.*, allegory, fable, and parable; *qq.v.*); from some proverbs; or from other kinds of enigma (the logogriph, the long riddling passage properly called an enigma, the rebus [*q.v.*], and the epigram; *q.v.*).

Robert Petsch (see *Bibliography*) recognizes two main kinds of riddle: the descriptive riddle, and the shrewd or witty question. These are differentiated in subject, use of traditional formulas, and in relationship to culture.

Descriptive Riddles.—These describe an animal, person, plant, or object, in an intentionally enigmatic manner, to suggest something different from the correct answer. "What runs about all day and lies under the bed at night?" suggests "A dog" but the answer is "A shoe." The description usually consists of one general and one specific element. The general element stands first and is to be understood metaphorically. Thus, in an English rhyming riddle of ancient origin, with counterparts in France, Sweden, Denmark, Finland, Switzerland, and Germany, beginning "Humpty Dumpty sat on a wall/ Humpty Dumpty had a great fall," the name seems to describe a man. And in

> Little Nancy Etticoat
> In a white petticoat
> And a red nose:
> The longer she stands
> The shorter she grows.

a girl seems to be described. The second element, to be understood literally, appears to contradict the first. Humpty Dumpty cannot be put together again, because he is an egg; Nancy Etticoat grows shorter the longer she stands, because she is a lighted candle.

Either element may be implied. Thus, a general element is lacking in the "cow-riddle": "Two lookers, two crookers, two fly-flappers,/ Four walkers, four hang-downers, and one switch-about," but the puzzling names for eyes, horns, etc., provide the difficulty. A few simple riddles, such as the Araucanian "It is stretched out in the path"—"A snake"; and "Jumping, it moves along the path"—"A toad," seem to lack the contradictory element, but may have a puzzling quality in the original language. Riddles of this sort are characteristic of relatively primitive cultures. An apparently late development is the use of puns: *e.g.*, "Black and white and red all over"—"A newspaper," in which both "red" and "all over" are to be understood in more than one sense.

Descriptive riddles may begin with a request for solution ("Here's a hard one"), a formula ("Riddle me, riddle me ree") or a suggestion of locality ("As I was walking over London

Bridge"), and may end with a threat, or the promise of a reward.

Traditional descriptive riddles describe familiar plants, animals, objects, natural phenomena, and parts of the body. Abstract ideas, such as love or anger, are not found as answers. Hunger and death occur occasionally, generally in riddles of literary origin. The worldwide comparison of a year with a tree, with 12 limbs, 30 branches, and 365 leaves, each black on one side and white on the other, seems to be a literary invention accepted by the "folk."

Descriptive riddles deal with appearance, not function. Thus, an egg is "A little white house without door or window," not something to eat or something from which a chicken hatches. Paradoxical riddles (*e.g.*, "What grows bigger the more you take from it?"—"A hole." "The man who made it did not want it; the man who bought it did not use it; the man who used it did not know it"—"A coffin") are descriptions in terms of action.

"Humpty Dumpty," "Little Nancy Etticoat," the worldwide "fish-riddle"—"Robbers came to our house/ And we were all in./ The house leaped out at the windows/ And we were all ta'en" (fish caught in a net)—and many other versifications are the work of folk poets. At two periods when riddles were popular in England, in the 10th century, and at the Renaissance, many riddles were versified and new ones invented. Some of the earliest Anglo-Saxon riddles are in the Exeter Book (*q.v.*). At the Renaissance many early riddles were given a more polished form. For example, the comparison of a bird to a snowflake, known to Herodotus, became the 17th-century

> White bird featherless
> Flew from Paradise,
> Perched upon the castle wall.
> Up came Lord John Landless (*i.e.*, the sun)
> Took it up handless,
> And rode away horseless
> To the king's white hall.

which alludes to the legend of the wingless bird of Paradise. This is also known in Scottish, German, and Swedish versions.

Descriptive riddles are universal. They rarely occur in folktales and ballads, although in Germanic legends the winning of a bride may depend on the answer to a riddle. A rare example of a descriptive riddle in a folktale is that asked by the Sphinx, the monster that terrorized the Boeotian Thebans: "What has one voice, and walks on four legs in the morning, two at noon, and three in the evening?" The answer was given by Oedipus: "A man, who crawls on all fours in infancy, walks on two feet when grown, and leans on a staff when aged."

The origin of riddles and their place in folk culture have been much discussed. Johan Huizinga calls them evidence of the play element in folk culture (*Homo Ludens*, 1949). As tests of wit and ingenuity they may be used in rituals, especially of initiation.

In one kind of descriptive riddle, things characterize themselves by speaking, as in the Basque " 'Let's go, let's go!' 'Let's stay, let's stay!' 'Let's play, let's play!' "—"River," "Stone," and "Fish." Perhaps the most widespread dialogue riddle is " 'Zigzag, where are you going?' 'Bald is your crown, what do you care?' 'Hair will grow on my head/ Before the straightening of your crooked steps' " (the mown hayfield speaks to the winding brook flowing through it), found from Wales to India.

The "neck-riddle" describes something known only to the asker, and, by its proving insoluble, a condemned man may save himself. The earliest example, in the Book of Judges 14, although not involving such a serious penalty, can only be solved by someone sharing the secret. Samson offers a reward to anyone who, in seven days, solves the riddle "Out of the eater came something to eat,/ Out of the strong came something sweet" (honey made by bees that had settled in a dead lion that he had seen).

Questions.—Lacking a generic name in English, shrewd or witty questions are classed with riddles. They are of ancient origin. Those in English, German, and Scandinavian ballads (*e.g.*, "What is whiter than milk?"—"Snow" and "What is deeper than the sea?"—"Hell") have parallels in the Sanskrit Rigveda, and may be associated with ancient rituals. A classical example, the Greek "What is the strongest of all things?"—"Love: iron is strong, but the blacksmith is stronger, and love can subdue the blacksmith," has been widely translated. Questions of this sort have only been reported in the higher cultures.

Shrewd questions may be classified by subject and form. Those dealing with letters of the alphabet, words, and symbols are generally statements calling for interpretation: *e.g.*, "ICUR YY 4 me" ("I see you are too wise for me"); "What is in the middle of Paris?"—"R"; "Spell 'dry grass' with 3 letters?"—"Hay." The influence of school in such riddles (sometimes called "catch riddles") is clear. An ancient variety of the shrewd question is catechetical in character. Juvenal's scornful allusion to those who ask who was Achilles' nurse, and Suetonius' remark that grammarians ask what song the sirens sang, imply use of question and answer in instruction. Medieval collections of biblical questions (*e.g.*, "Who died but was not born?"—"Adam") have modern parallels: *e.g.*, "Why did Cain kill his brother?" "Because he was able."

Shrewd questions may be serious or humorous. Arithmetical questions such as "One friend said to another 'Give me a dollar, and I'll have twice as much as you.' How many dollars did they have?"—"Five and seven," are parodied in, for example, "If you had five pennies and spent two and lost three, what would you have in your pocket?"—"A hole." Questions such as "What is the difference between . . . and . . . ?" or "Why is . . . like . . . ?" usually contain puns and are probably modern. Such catch questions as these seem to be known only in European cultures.

RIDGWAY, MATTHEW BUNKER (1895–), U.S. army officer who, during World War II, was responsible for the planning and execution of the first major airborne assault in the history of the U.S. Army with the attack on Sicily in July 1943. He was born at Fort Monroe, Va., March 3, 1895, and graduated from the United States Military Academy in 1917. Before World War II he served in various staff positions. As commanding general of the 82nd Airborne Division, he parachuted with his troops into Normandy in 1944 and subsequently led the 18th Airborne Corps in action in the Netherlands, Belgium, and Germany.

Assuming command of the U.S. 8th Army in Korea during the Chinese Communist offensive in late 1950, Ridgway rallied the United Nations forces and initiated a counteroffensive that drove the enemy out of South Korea. (*See* KOREAN WAR.) Assigned in 1951 as the overall Allied commander in the Far East, succeeding Gen. Douglas MacArthur, he continued the successful defense of the Republic of Korea and assisted in the rehabilitation of Japan. In 1952 he succeeded Gen. Dwight D. Eisenhower as supreme commander, Allied forces in Europe, and in 1953 was appointed chief of staff of the U.S. Army. He retired in 1955, having reached the rank of general in 1951. Ridgway's war memoirs appeared in 1956 under the title of *Soldier.* (W. ST.)

RIDING, a Scandinavian term for the third part of a shire or county, *e.g.*, the ridings of Yorkshire and of Lindsey in Lincolnshire. In Iceland the third part of a *thing,* which corresponds roughly to an English county, was called *thrithjungr;* in Norway, however, the *thrithjungr* seems to have been an ecclesiastical division. To the riding were brought causes which could not be determined in the wapentake, and a matter which could not be determined in the riding was brought into the court of the shire. There is abundant evidence that riding courts were held after the Norman Conquest.

Each of the ridings of Yorkshire has its own lord lieutenant and commission of the peace and, under the Local Government Act of 1888, forms a separate administrative county. They are distinguished as the north, east, and west ridings.

RIDING: *see* HORSEMANSHIP AND RIDING.

RIDLEY, NICHOLAS (*c.* 1503–1555), English Reformer

and martyr, who made his mark as one of the best academic brains in the first generation of the English Reformation. Born about 1503, the eldest son of Christopher Ridley (younger son of a landed gentleman), possibly of Unthank Hall in Northumberland, he entered Pembroke Hall, Cambridge, in 1518, proceeding B.A. in 1522 and M.A. in 1525. After a period of study in Paris and Louvain, he returned to a university career at Cambridge. He began to show sympathies with Reformed doctrines about 1534 and became chaplain to Archbishop Thomas Cranmer in 1537. He took a leading part in the general conversion of Cambridge into that Reformist seminary which was to contribute so much to the intellectual life of English Protestantism. In 1540 he was elected master of his college, having meanwhile obtained promotion in the church (vicar of Herne in Kent, 1538). During the last years of Henry VIII, when a reaction toward Catholicism had set in, he attracted attention as a suspected heretic (1543). As soon as Edward VI's accession returned the Reformation to favour, Ridley was appointed bishop of Rochester (1547). In 1550, after the trial and condemnation of Edmund Bonner, in whose deprivation he had played a leading part, he was promoted to Bonner's see of London, which he rapidly made into the showpiece of Reformed England. Especially he caused much uproar by a campaign for the use of a plain communion table in place of the altar. On Mary's accession (1553) he was arrested. Tried at Oxford with Cranmer and Hugh Latimer, he was burned at the stake together with the latter on Oct. 16, 1555.

Ridley was rather younger than his colleagues in the period of England's move away from Rome, but his theological learning, efficiency, and stern character put him among the leaders. Apart from his martyrdom, his chief service to the Church of England lay in the fact that he contributed an element of a native tradition to the debates and decisions of Edward VI's reign, which were strongly guided by continental influences. Clear-sighted without being a fanatic, he played an important part in assisting Cranmer to lay the foundations of Anglican doctrine.

BIBLIOGRAPHY.—Ridley's *Works*, ed. by H. Christmas (1841); J. G. Ridley, *Nicholas Ridley* (1957). For Ridley's part in the Reformation *see* also C. H. E. Smyth, *Cranmer and the Reformation under Edward VI* (1926). (G. R. E.)

RIDOLFI (DI RIDOLFO), **ROBERTO** (1531–1612), Italian-born conspirator whose name has been given to the plot (1570–71) to overthrow Elizabeth I of England, place the imprisoned Mary Stuart, queen of Scots, on the throne, and marry her to a Catholic, Thomas Howard, duke of Norfolk, was born at Florence on Nov. 18, 1531. He was trained as a merchant and banker, and settled in London about 1555 as a mercantile agent. Although employed by Elizabeth's government in financial business, his ardent Catholic beliefs led him to interfere in politics on behalf of discontented English Catholics. These activities culminated in the plot in 1570–71. Ridolfi left London in March 1571 and visited the duke of Alva, Pope Pius V, and Philip II, in order to describe his plot and to gain the necessary military and financial support. But before the scheme could mature, Ridolfi's messenger, Charles Baillie, was arrested at Dover; his confession, and the letters he was carrying, led to the capture of many of the English conspirators. Norfolk was executed in June 1572. Ridolfi, who was still abroad when the plot was discovered, returned to Florence, where he died on Feb. 18, 1612. (T. I. R.)

RIEBEECK, JAN VAN (1619–1677), Dutch East India Company official, was the founder in 1652 of the settlement that became Cape Town and was primarily responsible for the introduction of free burghers (colonists) which inaugurated the history of white settlement in South Africa. Born at Culemborg, in Holland, on April 21, 1619, he joined the company as an assistant surgeon in April 1639 and sailed that month to Batavia. He achieved rapid promotion in the clerical service, went to Japan (1643), and in 1645 took charge of the company trading station at Tonking (Tonkin). After returning to Batavia in 1647, he left in January 1648 for Holland, where he was dismissed for having defied the ban on private trading by company officials when he was in Tonking. In 1651 he interested himself in the company's preparations for an expedition to establish a provisioning station at the Cape for ships plying the East India route. Having previously visited the Cape, he compiled a memorandum for the company and was placed in command of the expedition (December 1651).

Riebeeck's *Journal* records the arrival in Table Bay of his ship, the "Drommedaris," on April 6, 1652. When the expedition had landed, work began on the construction of a fort and garden, while cattle and sheep were bartered from local Hottentot clans. After early setbacks caused by crop failures and Hottentot thefts of cattle, Riebeeck informed the company in 1655 that his mission would fail unless free burghers, working their own farms, were introduced. His suggestion was adopted in 1657 with the establishment of former company servants, who were granted "letters of freedom" under conditions which protected company interests. He also encouraged the importation of slaves and the exploration of the interior and fought a "war" with the Hottentots (1659–60). He enforced no colour bar, and interracial marriages were permitted, provided both parties were Christians. When he left the Cape in May 1662, after pressing throughout his stay for a transfer to the East, there were over 100 colonists proper, including the wives and children of free burghers, and the Cape, though still a financial burden, was fulfilling its function as a provisioning station. He returned to Batavia and in 1665 became secretary to the Council of India, a post he retained until his death in Batavia on Jan. 18, 1677. A translation of Riebeeck's *Journal*, edited by H. B. Thom, was published in three volumes in 1952–58. For portrait, *see* article SOUTH AFRICA, REPUBLIC OF.

See C. L. Leipoldt, *Jan van Riebeeck* (1936). (N. G. GA.)

RIEGER, FRANTISEK LADISLAV (1818–1903), Czech political leader, a major representative of the more conservative element in the national reawakening, was born at Semily in Bohemia on Dec. 10, 1818. The son of a miller who wished him to follow the same calling, he secretly studied law with the encouragement of his mother, and at an early age was drawn into the Czech national movement. In April 1848 he headed a delegation to present the demands of the Czechs to the new Austrian government in Vienna; and in November he was one of the Czech representatives at the Kremsier (Kromeriz) Parliament (*see* AUSTRIA, EMPIRE OF). When this Parliament was dispersed (March 1849), Rieger went into exile in France, a country which was to remain of great significance to him. Returning home in 1851, he married the daughter of Frantisek Palacky (*q.v.*) in 1853. Having been refused an academic position in Prague, he brought out the *Slovnik Naucny*, 11 volumes (1850–74), the first encyclopaedia in Czech. In 1861 he founded the first important Czech newspaper, *Narodni Listy*.

In 1861 Rieger was elected to the Bohemian Diet and also to the lower house of the Austrian *Reichsrat* in Vienna; since Palacky had been nominated to the upper house, Rieger was thenceforward the political leader of the Czechs for most practical purposes. Friction with the dominant Germans caused Rieger to decide to withdraw from the *Reichsrat* in June 1863; and, except for a brief period in 1870–71, the Czechs maintained this boycott till 1879. The bitterest experience of the Czechs came in 1867, when the emperor Francis Joseph made his "Compromise" with Hungary, but refused to recognize the Czechs' claim to the same autonomous status as the Magyars. In that year Rieger went with Palacky to Moscow as part of a Pan-Slav gesture, which offended the Poles.

In 1869 Rieger had a secret audience with the French emperor Napoleon III, the news of which leaked out; in 1870 he took the lead in pro-French demonstrations. Criticism from his own people of these actions and the lack of any practical gain for the Czech nation led to the emergence of a new and more intransigent party called the Young Czechs. The younger generation regarded Rieger as too conservative and frowned on his association with the Bohemian nobility. It was increasingly felt that to boycott the *Reichsrat* left the German deputies in control at the expense of the Czechs. At last in 1879, when Eduard, Graf von Taaffe, headed a new government more favourable to the Slavs in its attitude, Rieger abandoned the policy of abstention and the Czech deputies returned to Vienna. In 1891 Rieger lost his parliamentary seat and retired from political life, after very nearly realizing a practical compromise between the Czechs and Germans of Bohemia. He

was, however, frustrated to the last by opposition from the Young Czechs, who then stepped into his political inheritance. He was created a baron in 1897.

Rieger took great interest in the municipal government of Prague and was particularly concerned with the establishment of the Czech National Theatre there—the foundation stone of this was laid in 1868, though a fire caused many years' delay before the theatre was opened. Rieger was also a champion of a Czech university in Prague; it had, indeed, been tacitly agreed before the Czechs returned to the *Reichsrat* in 1879 that the Charles University should be divided into separate German and Czech institutions, and, in 1881 to Rieger's great satisfaction, the independent Czech university emerged. He died in Prague on March 3, 1903. His *Vybrane řeči* ("Selected Speeches") appeared in 1924.

(E. WI.)

RIEL, LOUIS (1844–1885), French-Canadian political leader of discontents in western Canada, was born in St. Boniface, Red River Settlement, Oct. 22, 1844. He was educated at St. Boniface and, between 1858 and 1866, at the Sulpician Collège de Montréal, in Canada. After briefly studying law he secured employment as a clerk in St. Paul, Minn.

During 1868–69, arrangements for the transfer of the Hudson's Bay Company territories to Canada aroused the local inhabitants, largely made up of French and Scotch métis (having some Indian blood). Riel assumed leadership of these discontents, and in 1869, not only halted Canadian surveyors but organized the French métis into a politico-military party which prevented William McDougall, the governor-designate, from entering Red River. He then seized Ft. Garry (Winnipeg) and established a provisional government of which he became president. In 1870 he sent delegates to Ottawa where, in May, the Canadian Parliament adopted legislation (Manitoba Act) by which the province of Manitoba, which included Red River, was established. However, such was the emotional excitement aroused in Ontario by the execution of an Ontario Orangeman, Thomas Scott, by a métis court-martial, that the Canadian government refused to fulfill the promise of amnesty to the insurgents. When Canada sent a military expedition to Red River to maintain order, Riel and his associates fled.

Several times elected a member of the Canadian Parliament, Riel did not take his seat, and in 1875 was outlawed for five years. After spending some months in mental hospitals in Montreal and Quebec, he moved to Montana. In 1883 he became a U.S. citizen, and endeavoured to organize the American métis on behalf of the Republican Party.

Aroused by the westward expansion of Canadian settlement and encouraged by discontented whites, the métis of the Saskatchewan Valley sent for Riel in June 1884, to lead the Second Riel Rebellion. In March 1885 he formed a provisional government and solicited the support of the Indians. Following his defeat by Canadian government forces, Riel was tried for treason and executed at Regina, Nov. 16, 1885. His death increased racial and religious tensions in Canada, severely damaged the Conservative Party in Quebec, and gave rise to a French-Canadian "nationalist" movement under Honoré Mercier.

(G. F. G. S.)

RIEMANN, GEORG FRIEDRICH BERNHARD (1826–1866), German mathematician, exerted a profound influence on several branches of mathematics, particularly geometry and function theory (*see* RIEMANNIAN GEOMETRY). He was born on Sept. 17, 1826, in the village of Breselenz in Hanover, the son of a Lutheran pastor. From 1846 to 1851 he studied at the universities of Göttingen and Berlin.

In 1851 he obtained his doctorate at Göttingen with his celebrated dissertation, "Foundations for a General Theory of Functions of a Complex Variable." In it he set forth an approach to function theory based on general principles and geometrical ideas rather than on formal calculation. His probationary essay for admission to the faculty in 1853 was "On the Representation of a Function by Means of a Trigonometrical Series." His trial lecture for admission to the faculty in 1854 was "On the Hypotheses Which Form the Foundation of Geometry." In this he introduced a new approach to geometry which covered ordinary Euclidean geometry, the non-Euclidean geometry of Nikolai Lobachevski, Johann Bolyai and C. F. Gauss, and other possible non-Euclidean geometries as special cases. His idea was to study the properties of a geometrical space locally rather than to insist on one overall framework for the whole space.

He became successively a *Privatdozent* (official but unpaid lecturer), assistant professor (1857), and professor (1859), succeeding P. G. L. Dirichlet (who had succeeded Gauss four years earlier). Tuberculosis began to take its toll in the early 1860s and Riemann died on July 19, 1866, at Selasca, in northern Italy.

In addition to the work mentioned above he published equally significant papers on Abelian functions, the distribution of primes, and air waves of finite amplitude. His posthumously published papers and even the fragments published in his collected works proved to be rich in new ideas. Some idea of his influence can be obtained from the impressive list of methods, theorems, and concepts that bear his name: the Riemann approach to function theory, the Riemann-Roch theorem on algebraic functions, Riemann surfaces, the Riemann mapping theorem, the Riemann integral, the Riemann-Lebesgue lemma on trigonometrical integrals, the Riemann method in the theory of trigonometrical series, Riemannian geometry, Riemann curvature, Riemann matrices in the theory of Abelian functions, the Riemann zeta function, the Riemann hypothesis, the Riemann method of solving hyperbolic partial differential equations, Riemann-Liouville integrals of fractional order and others. In fact, it has been said that he anticipated a large part of 20th-century research in geometry and analysis.

Riemann was interested in physical problems and for a time was an assistant in the Göttingen physics laboratory. His idea of defining analytic functions and geometrical spaces in terms of their local properties no doubt was motivated by physical considerations. His approach to geometry made possible the general relativity theory of Albert Einstein. Riemann also gave the first mathematical treatment of shock waves.

In view of the tremendous importance of Riemann in the history of mathematics, it is somewhat surprising that his collected works occupy only one moderately sized volume edited by R. Dedekind and H. Weber (1876; second edition, 1892; French translation, 1898; reprint of second German edition with the 1902 supplement, 1953).

(P. T. B.)

RIEMANNIAN GEOMETRY, one of a group of non-Euclidean systems that reject Euclid's postulate of parallels. Founded by G. F. B. Riemann (*q.v.*) in 1854, it is the geometry of a coordinate space $(x^1, \ldots, x^n)$ in which there is a nondegenerate quadratic differential form called the element of arc:

$$ds^2 = \sum_{1 \le i,k \le n} g_{ik}(x)dx^i dx^k$$

The geometry reduces to Euclidean geometry if the element of arc takes the special form $ds^2 = (dx^1)^2 + \ldots + (dx^n)^2$. The two-dimensional case was considered before Riemann by C. F. Gauss, as the intrinsic geometry on a surface in ordinary Euclidean space. In pure mathematics the differential form ds^2 is generally supposed to be positive definite, an assumption that is essential to many of the important consequences. In applications to general relativity, where the Riemannian space is the physical universe, ds^2 is supposed to be hyperbolic; *i.e.*, reducible to a sum

of squares minus the square of a linear differential form (*see* GEOMETRY, NON-EUCLIDEAN).

Basic Properties.—The ds^2 allows the definition of the arc length of a curve $x^i = x^i(t)$ as the integral

$$s = \int_{t_0}^{t_1} \sqrt{\left| \sum_{i,k} g_{ik} \frac{dx^i}{dt} \frac{dx^k}{dt} \right|}\, dt \tag{1}$$

Geodesics are curves that are shortest between any two of their points, sufficiently near to each other. An n-dimensional domain has a volume given by the integral $\int \sqrt{|g|}\, dx^1 \ldots dx^n$, where g is the determinant of g_{ik}.

The coordinates x^i are local coordinates in the sense that they can be subjected to a general differentiable transformation $x'^i = f^i(x^1, \ldots, x^n)$, where $i = 1, \ldots, n$ with nonvanishing Jacobian determinant (*see* DIFFERENTIAL GEOMETRY). For ds^2 to be invariant under such changes of local coordinates g_{ik} should be transformed according to the equations

$$g_{ik} = \sum_{j,l} g'_{jl} \frac{\partial x'^j}{\partial x^i} \frac{\partial x'^l}{\partial x^k} \text{ where } i, j, k, l = 1, \ldots, n \tag{2}$$

and are therefore the components of a symmetric covariant tensor field of order two. The elements g^{jl} of the inverse matrix of the matrix (g_{ik}), which are related to g_{ik} by the equations

$$\sum_k g_{ik} g^{kl} = \delta_i^l = \begin{cases} 1, & i = l \\ 0, & i \neq l \end{cases} \text{ where } i, k, l = 1, \ldots, n \tag{3}$$

are the components of a symmetric contravariant tensor field of order two. The fundamental tensors g_{ik} and g^{jl} can be used to derive new tensors from those given. Thus, if $A^{ij}{}_k$ is a tensor field,

$$A^i_{jk} = \sum_l g_{lj} A^{il}{}_k, \; A^{ijk} = \sum_l g^{kl} A^{ij}{}_l$$

are new tensor fields. They are said to be associated to each other, and the process is described as that of raising or lowering indices. The length of a vector A^i is

$$|A| = \sqrt{\left| \sum_{i,k} g_{ik} A^i A^k \right|}$$

The angle θ between two vectors A^i, B^j of lengths different from zero is defined by the formula

$$\cos\theta = \sum_{i,k} g_{ik} A^i B^k / |A| \cdot |B|$$

From the fundamental tensor g_{ik} E. B. Christoffel (*see* TENSOR ANALYSIS) constructed in 1869 the quantities

$$\Gamma_{ijk} = \frac{1}{2}\left(\frac{\partial g_{ij}}{\partial x^k} + \frac{\partial g_{jk}}{\partial x^i} - \frac{\partial g_{ik}}{\partial x^j} \right), \; \Gamma^i_{jk} = \sum_l g^{il} \Gamma_{ljk} \tag{4}$$

These are not the components of a tensor, but can be used to define the covariant derivative of a tensor field, giving a tensor field of one more covariant order. In the cases of contravariant and covariant vector fields and that of a mixed tensor field of type (1,1), their covariant derivatives are respectively

$$\begin{aligned} A^i{}_{,k} &= \frac{\partial A^i}{\partial x^k} + \sum_j \Gamma^i_{jk} A^j \\ A_{i,k} &= \frac{\partial A_i}{\partial x^k} - \sum_j \Gamma_i{}^j{}_k A_j \\ B^i{}_{j,k} &= \frac{\partial B^i{}_j}{\partial x^k} + \sum_l (\Gamma_l{}^i{}_k B^l{}_j - \Gamma_j{}^l{}_k B^i{}_l) \end{aligned} \tag{5}$$

Similar expressions are valid for the covariant derivatives of more general tensor fields. The covariant derivative of g_{ik} vanishes identically. Conversely, Γ^j_{ik} can be characterized as the quantities that are symmetric in i,k and for which the covariant derivative of the fundamental tensor is zero. In geometrical language Γ^j_{ik} defines a parallel displacement of vectors along curves; the vector field A^k is parallel along a curve $x^i = x^i(t)$ if

$$\frac{dA^i}{dt} + \sum_{j,k} \Gamma^i_{jk} \frac{dx^j}{dt} A^k = 0, \text{ where } i, j, k = 1, \ldots, n \tag{6}$$

This is called the Levi-Civita parallelism. It is an affine connection in the general terminology of connections, but is one related in a special way to the Riemannian metric. Under the parallelism of Levi-Civita the scalar product of two vectors remains unchanged. A geodesic is either a curve of zero length or one along which the unit tangent vector is parallel. The former possibility does not appear in the case of a positive definite metric.

The notion of curvature arises in studying the parallel displacement of a vector around a closed curve. When the closed curve is an infinitesimal parallelogram the new position of the vector can be obtained from the initial position by an infinitesimal rotation. Analytically this association is described by the Riemann-Christoffel curvature tensor. Its expression is

$$R_i{}^j{}_{kl} = \frac{\partial \Gamma^j_{il}}{\partial x^k} - \frac{\partial \Gamma^j_{ik}}{\partial x^l} + \sum_m (\Gamma^m_{il} \Gamma^j_{mk} - \Gamma^m_{ik} \Gamma^j_{ml}), \; R_{ijkl} = \sum_m g_{jm} R_i{}^m{}_{kl} \tag{7}$$

The components of the curvature tensor have the following symmetry properties

$$\begin{aligned} R_{ijkl} &= -R_{jikl} = -R_{ijlk} \\ R_{ijkl} &= R_{klij} \\ R_{ijkl} &+ R_{iklj} + R_{iljk} = 0 \end{aligned} \tag{8}$$

As a result there are $n^2(n^2-1)/12$ independent components; *e.g.*, 6 for a three-space, 20 for a four-space, and 1 for a two-space. In the latter case the quotient $K = -R_{1212}/g$ is a scalar and is the Gaussian curvature (*see* SPACE-TIME: *Riemann's Geometry*). If a vector is given a parallel displacement around a closed curve on a surface, it returns with its direction changed by an amount equal to $\int K d\sigma$, the Gaussian curvature of the surface integrated over the surface area bounded by the closed curve. As a consequence, the excess (over π) of the angle sum in any geodesic triangle is $\int K d\sigma$, a famous theorem due to Gauss.

In the case of three or more dimensions the curvature properties can no longer be expressed by a single magnitude, but require for their description the whole curvature tensor. The concept of Gaussian curvature is replaced by that of Riemannian curvature or sectional curvature. This is, at any point p and any plane element (two-dimensional) through p, the Gaussian curvature of the geodesic surface through p and tangent to the plane element. If the latter is spanned by the vectors A^i, B^j, the Riemannian curvature is given by the formula

$$K = -\sum_{i,j,k,l} R_{ijkl} A^i A^k B^j B^l \Big/ \sum_{i,j,k,l} (g_{ik} g_{jl} - g_{il} g_{jk}) A^i A^k B^j B^l \tag{9}$$

In general, K will depend both on the point and on the plane element through it. In other words, with regard to curvature, the space may be nonhomogeneous as well as anisotropic. However, for $n \geq 3$, F. Schur's theorem says that if K is everywhere isotropic (*i.e.*, independent of the choice of the plane element at every point) it is constant throughout. Riemannian spaces for which the Riemannian curvature is constant for all points and all plane elements through them are said to be of constant curvature. They include the Euclidean and non-Euclidean spaces. Analytically they are characterized by the conditions

$$R_{ijkl} = -K(g_{ik} g_{jl} - g_{il} g_{jk})$$

with constant K. The curvature tensor gives by contraction the symmetric tensor $R_{ik} = \sum_j R_i{}^j{}_{jk}$ called the Ricci tensor. A further contraction gives the scalar invariant $R = \sum_i R_i{}^i$.

Potential Theory on a Riemannian Manifold.—A Riemannian manifold is a differentiable manifold with a positive definite Riemannian metric (*see* MANIFOLDS). One of the main

reasons for the importance of Riemannian geometry is that such a metric exists on every manifold and can therefore be used to describe its properties. If the manifold is oriented (*i.e.*, if a covering exists such that the Jacobian determinants of overlapping local coordinate systems are everywhere positive) the orientation of the manifold defines an orientation in every tangent or cotangent space (*i.e.*, the space of covariant vectors). The Riemannian metric on the manifold gives rise to an inner product in the cotangent (or tangent) space, which defines the lengths of vectors and, more generally, the r-dimensional measures of r-vectors. To an r-vector L of the cotangent space there exists a uniquely determined $(n-r)$-vector $*L$ having the properties: 1) $*L$ is completely perpendicular to L; 2) the r-dimensional measure of L is equal to the $(n-r)$-dimensional measure of $*L$; 3) L and $*L$ span the whole oriented cotangent space. This passage from L to $*L$ is a generalization, for $n = 3$, $r = 2$, of the vector product of vectors in ordinary vector analysis (*see* VECTOR ANALYSIS). By linearity this star operator can be extended into a linear operator which maps an antisymmetric covariant tensor of order r into one of order $n-r$. If the former has the components $A_{i1} \ldots _{ir}$, the components of $*A$ are given by the formula

$$(*A)_{i_1} \ldots _{i_{n-r}} = \frac{1}{r!}\sqrt{g} \sum \epsilon_{j_1} \ldots _{j_r i_1} \ldots _{i_{n-r}} g^{j_1 k_1} \ldots g^{j_r k_r} A_{k_1} \ldots _{k_r} \quad (10)$$

In this sum $\epsilon_{i_1} \ldots _{i_n}$ is equal to zero if the indices are not all distinct and is otherwise equal to 1 or -1, according as $i_1, \ldots, i_n$ form an even or odd permutation of $1, \ldots, n$, while the summation is taken over all repeated indices from 1 to n. Combination with the operator of exterior differentiation gives rise to the further operators

$$\delta = (-1)^{nr+n+1} *d*, \quad \Delta = d\delta + \delta d \quad (11)$$

When expressed in terms of exterior differential forms, the star operator converts a form of degree r into one of degree $n-r$, d increases the degree by one, δ decreases it by one, while Δ keeps the degree unchanged. The operator Δ is called the Laplace operator, generalizing the one with the same name in Euclidean space. An exterior differential form ω such that $\Delta\omega = 0$ is called harmonic.

For compact orientable Riemannian manifolds of class C^∞ the use of harmonic forms is justified by the following fundamental decomposition theorem: Every C^∞ exterior differential form can be expressed in one and only one way as a sum $\omega = \omega_1 + d\eta + \delta\zeta$ where ω_1 is harmonic. It follows that every closed form differs by a derived form from a harmonic form, and that the latter is uniquely determined. The dimension of the space of harmonic forms of degree r is the rth Betti number of the manifold. Every cohomology class (with real coefficients) contains one and only one harmonic form. These results give a hold on the study of homological properties of a manifold (*i.e.*, topological properties pertaining to homology or bounding), when certain analytical behaviour of the manifold is known. This is, for instance, the case of the manifolds of the classical Lie groups (*e.g.*, the unitary group and the rotation group) for which the Betti numbers can be determined by the use of this theorem (*see* GROUPS, CONTINUOUS).

Among the important geometrical applications of harmonic forms is the analysis of the homological properties of compact Hermitian-Kählerian manifolds. A complex manifold with the local coordinates $z^1, \ldots, z^n$ is called Hermitian, if there is given a positive definite Hermitian differential form

$$\sum_{1 \le i,k \le n} h_{ik}(z,\bar{z}) dz^i d\bar{z}^k$$

To this is associated a real-valued quadratic exterior differential form

$$\frac{i}{2} \sum_{i,k} h_{ik} dz^i \wedge d\bar{z}^k$$

If the latter is closed, the Hermitian manifold is called Kählerian. The complex projective space of n dimensions and, in particular, the Riemann sphere in the theory of functions of one complex variable, are Kählerian manifolds. The same is true of any nonsingular algebraic variety in complex projective space. W. V. D. Hodge, the initiator of harmonic forms, gave a deep analysis of the differential forms on compact Kählerian manifolds. Instead of the real differential forms it is necessary to consider on a complex manifold complex-valued exterior differential forms. A form which can locally be written

$$\sum A_{i_1} \ldots _{i_p j_1} \ldots _{j_q} dz^{i_1} \wedge \ldots \wedge dz^{i_p} \wedge d\bar{z}^{j_1} \wedge \ldots \wedge d\bar{z}^{j_q}$$

is said to be bihomogeneous of bidegree (p,q). Let h_{pq} be the dimension of the space of complex-valued harmonic forms of bidegree (p,q). These are integers which describe the global properties of compact Kählerian manifolds. They are symmetric in p,q: $h_{pq} = h_{qp}$, and are "finer" than the Betti numbers. In fact, the rth Betti number is equal to the sum $\sum_{p+q=r} h_{pq}$

Space-forms and Symmetric Riemannian Spaces.—Riemannian manifolds of constant curvature K, on account of the very restrictive curvature property, can be described rather explicitly. Examples of such manifolds are, for $K = 0$, the Euclidean space; for $K > 0$, the sphere of radius $1/\sqrt{K}$ in Euclidean space; and, for $K < 0$, the hyperbolic space of curvature K. A Riemannian manifold is called complete if every geodesic can be extended indefinitely, where return of the point to its original position and repetition of the geodesic are allowed. The completeness assumption is to exclude those Riemannian manifolds which are open subsets of a larger one. A complete Riemannian manifold of constant curvature is called a space-form. Its universal covering manifold has the further property of being simply connected. The fundamental theorem on space-forms asserts that a complete simply connected Riemannian manifold of constant curvature is isometric to the Euclidean space, the spherical space, or the hyperbolic space mentioned above, according as the curvature is zero, positive, or negative. The problem of determination of space-forms then reduces to that of determination of discontinuous subgroups Γ of motions without fixed points in these three spaces, the space-form being a quotient space relative to Γ. The multitude of such subgroups depends very much on the sign of curvature. Roughly speaking, they are relatively few if K is positive and far more numerous if K is negative, while the case of zero curvature occupies an intermediate position. In fact, an even-dimensional space-form of positive curvature is either the spherical space or the elliptic space obtained from the former by the identification of its antipodal points. Odd-dimensional space-forms of positive curvature exist already in abundance. The question of three-dimensional Euclidean space-forms (*i.e.*, zero curvature) is related to crystallography (*q.v.*), where the discontinuous subgroups of the group of Euclidean motions are studied. Space-forms give an important source of examples of manifolds.

In applications of Riemannian geometry the condition of constant Riemannian curvature is too restrictive. A wider and more important class of Riemannian manifolds is the symmetric Riemannian spaces of E. J. Cartan (*q.v.*). These are the Riemannian spaces which locally have the property that the symmetry at every point is an isometry with the point as an isolated fixed point. This is equivalent to the property that the sectional curvature is preserved under the parallelism of Levi-Civita. Analytically it is expressed by the condition that the covariant derivative of the Riemann-Christoffel curvature tensor is zero. Symmetric Riemannian spaces include the spaces of simple Lie groups and spaces which play an important role in the theory of automorphic functions of several complex variables.

Global Problems.—Among the most important problems in Riemannian geometry are those which relate the local curvature properties with the behaviour of the manifold as a whole. Thus a theorem of O. Bonnet says that if a two-dimensional complete Riemannian manifold has a positive lower bound for its curvature, it must be compact. The Gauss-Bonnet formula then implies that its Euler characteristic is positive and hence that the manifold is homeomorphic to a sphere. The delicacy of such

problems can be realized when it is observed that a two-dimensional Riemannian manifold of positive curvature need not be compact.

Global problems in Riemannian geometry can generally be classified into three categories: characteristic classes, implications of local properties of curvature, and behaviour of geodesics. The simplest result of the first category is the Gauss-Bonnet formula, expressing the Euler-Poincaré characteristic of a compact orientable Riemannian manifold M as an integral: $\chi(M) = \int I dV$, where dV is the volume element and the integrand I is zero when n is odd and is equal to

$$\frac{g^{-1}}{(2\pi)^{\frac{n}{2}} 2^n \left(\frac{n}{2}\right)!} \sum \epsilon_{i_1 \ldots i_n \epsilon_{j_1 \ldots j_n}} R_{i_1 i_2 j_1 j_2} \cdots R_{i_{n-1} i_n j_{n-1} j_n}$$

when n is even, the summation being over all the repeated indices from 1 to n. It follows from the formula that the Euler-Poincaré characteristic of a four-dimensional compact Riemannian manifold is positive, if the sectional curvature is positive for all plane elements or negative for all plane elements. The formula has a generalization for a domain with boundary in the manifold; as such it is a generalization of the formula for the sum of solid angles of a simplex. The Euler-Poincaré characteristic is only one of a set of invariants derived from the differentiable structure of the manifold and independent of the choice of the Riemannian metric on it. Further invariants of this kind are the Pontryagin characteristic classes introduced by L. Pontryagin in 1942. These are cohomology classes with real coefficients and can all be described in the sense of De Rham's theorem by exterior differential forms constructed explicitly from the curvature tensor.

The problems of the second category begin with a study of Riemannian manifolds whose sectional curvature keeps the same sign. If the sectional curvature is nonpositive and the manifold is complete, its universal covering manifold is homeomorphic to the Euclidean space. From this follow properties of the fundamental group of compact manifolds of negative curvature, one of which says that it is not Abelian. If the sectional curvature has a positive lower bound, Bonnet's theorem mentioned above can be generalized to n dimensions, so that the manifold is compact. S. B. Myers observed that the same conclusion remains true under the weaker hypothesis that the Ricci curvature tensor majorizes a fixed positive definite tensor. As a consequence, the fundamental group of a compact Riemannian manifold with a positive definite Ricci tensor is finite and hence its first Betti number is zero. The last conclusion was also shown by S. Bochner (1948) by applying the theorem on harmonic forms. Bochner's method also gives sufficient local conditions on curvature for the vanishing of the higher Betti numbers. J. L. Synge showed that an even-dimensional orientable Riemannian manifold with a positive lower bound for the sectional curvature is simply connected. While these results deal with the topological implications of the curvature properties of a Riemannian manifold, a more decisive theorem was demonstrated by H. E. Rauch in 1951. Rauch's theorem asserts that if the sectional curvature of a complete simply connected Riemannian manifold satisfies the inequalities $0 < hL < K \leq L$, where $h = 0.74$, then M is homeomorphic to a sphere; this value of h is not the best possible.

The behaviour of the geodesics on a Riemannian manifold has been the object of extensive study. If the manifold is of constant negative curvature, the geodesic flow is ergodic. Another problem is that of closed geodesics. They certainly exist on a complete Riemannian manifold that is not simply connected, for the shortest curve in a free homotopy class of curves nonshrinkable to a point is a closed geodesic. The famous Lusternik-Schnirelmann theorem says that on a closed surface of genus zero there are at least three closed geodesics (*see* CRITICAL POINTS). A geodesic segment can be assigned an index, depending on the number of conjugate points on it. This notion has been found useful in homotopy problems in topology.

General Relativity.—The space of general relativity (*see* RELATIVITY) is a four-dimensional Riemannian space with an indefinite metric that can be written locally as $ds^2 = \omega_1^2 + \omega_2^2 + \omega_3^2 - \omega_4^2$, where $\omega_1, \ldots, \omega_4$ are linear differential forms. The components g_{ik} of the fundamental tensor define the gravitational potential. The light rays are the null curves defined by the differential equation $ds^2 = 0$, while the trajectories of particles without the action of external force are the geodesics. In this way the geometry of the space is not a priori given, but is determined by matter. An essential restriction on the metric is given by Einstein's field equations $R_{ik} = -\mathcal{H}(T_{ik} - \frac{1}{2} g_{ik} T)$, where T_{ik} is the impulse-energy tensor, T is the contraction of T_{ik} relative to the fundamental tensor, and $\mathcal{H}$ is a constant. Many attempts have been made, some by Einstein himself in his late years, to develop a unified field theory that would include both the gravitational and the electromagnetic fields. This leads to a generalization of Riemannian geometry to more general geometric objects, such as the Weyl geometry, the Kaluza five-dimensional metric, projective relativity of O. Veblen, and so on. The results are not conclusive.

(S. S. CH.)

RIENZO, COLA DI (1313–1354), the Roman tribune who tried unsuccessfully to apply his humanist ideas to practical politics, was born in Rome in 1313. After spending most of his youth at Anagni, he returned at the age of 20 to Rome, where he became a notary. In 1343 he was sent to Pope Clement VI at Avignon to plead the case of the Roman popular party. During his long stay at Avignon he was befriended by Petrarch, who was deeply impressed by his patriotic concern over the conditions in Rome.

Appointed notary of the *camera urbana* (the Roman city treasury) by Clement VI, Cola di Rienzo returned to Rome in 1344 and used his new position to press for reforms. Reviving earlier Roman hopes and inspired by his studies of Roman history and antiquities, he dreamed of restoring Rome to its past greatness. In 1347 he assumed the leadership of the popular party and, on May 20, denounced the oppressive rule of the nobles to a parliament on the Capitol, which entrusted him and the papal vicar with the government of the city. A few days later, a second parliament conferred on him dictatorial powers. He adopted the ancient title of tribune and, amid elaborate ceremonies which showed the impact of his antiquarian interests, he was dubbed knight of the Roman people on Aug. 1 and crowned tribune on Aug. 15.

Cola di Rienzo used his powers to subdue the nobility and to improve Rome's finances and administration. Not content with this, he declared all Italians to be Roman citizens (Aug. 1, 1347) and summoned Louis IV the Bavarian and Charles IV to Rome to defend their rival claims to the Holy Roman Empire. His invitation to the principal Italian cities and rulers to form a federation under Roman leadership met with scant response; and

his Italian policy helped to turn the pope against him. Though in November he succeeded in repulsing an attack by the Colonna (*q.v.*), he decided to submit to the pope; and, after a rising against him, he suddenly resigned office (Dec. 15) and fled from Rome shortly afterward. Excommunicated, Cola di Rienzo spent about two years in the Abruzzi among Spiritual Franciscans, where he came under the influence of Joachim of Fiore's prophecies. In 1350 he went to Prague and, announcing an early judgment and renewal of the church, implored Charles IV to come to Italy. Imprisoned by the archbishop of Prague (Ernest of Pardubitz) as an excommunicate, he was transferred, in 1352, to Avignon; but his trial for heresy ended, in 1353, with his absolution. As Pope Innocent VI decided to use him in the papal state, Rienzo joined Cardinal Albornoz (*q.v.*) in Perugia later in 1353 and was appointed Roman senator in July 1354. His arbitrary rule, however, roused growing opposition in Rome, and on Oct. 8, 1354, he perished in a popular rising.

His letters are edited by K. Burdach and P. Piur (1912).

RIESA, a town of East Germany in the *Bezirk* (district) of Dresden, German Democratic Republic. It is situated on the Elbe, 44 mi. (71 km.) NW of Dresden and 37 mi. (59 km.) E of Leipzig. Pop. (1962 est.) 38,235. It is the junction of the Berlin–Karl-Marx-Stadt and Leipzig–Dresden railway lines and the chief river port of northern Saxony. Riesa is an important industrial centre with steelworks, a rolling mill, match factory, tire factory, cotton mill, and oil refinery. The town grew up in the 12th century alongside a monastery founded in 1111. It received its municipal charter in 1623 but lost it shortly afterward. With the development of industry and railways in the 19th century Riesa regained its importance and was again given a municipal charter in 1859.

RIESENER, JEAN HENRI (1734–1806), French cabinetmaker, the greatest of his time, was born at Gladbeck, Ger., on July 4, 1734, the son of a courtroom usher. Coming to Paris as a young man, he began work under Jean Francois Oeben, whose widow he subsequently married, thereafter taking control of the Oeben workshop. Having qualified as a master craftsman in 1768, he embarked on a long and successful career. His first great achievement was the completion, in 1769, of the celebrated *bureau du roi* (now in the Louvre, Paris) that Oeben had begun for Louis XV; and this was followed by his supplying the contents for the king's *garde meuble* or personal furniture store. In recognition of this work he was appointed "ordinary cabinet maker to the king" (Louis XVI) in 1774; and from then onward he was the regular supplier of furniture to the queen, Marie Antoinette. He died in Paris on Jan. 6, 1806.

Riesener was a consummate craftsman. His graceful furniture is often richly finished with marquetry of exceptional delicacy and with perfectly carved bronzes. His early work naturally shows Oeben's influence in the strength and architectural quality of the design, but he gradually developed a more individual, more delicately conceived style. This was to become the pure Louis XVI style, with its rectilinear side view and harmoniously distributed ornamentation. Riesener used both European and exotic woods, with a preference for mahogany; he occasionally used lacquer and mother-of-pearl to enrich the surfaces of his works.

See Pierre Verlet, *Mobel von J. H. Riesener* (1955), for a description of many exquisite pieces of furniture now in museums or private collections in Europe and America. *See* also F. de Salverte, *Les Ébénistes français du XVIIIe siècle,* new ed. (1953). (S. Gr.)

RIETI, an ancient city of the region of Lazio, capital of the province of Rieti, central Italy, and seat of a bishopric, is situated on the Velino River among the Abruzzi Mountains 1,318 ft. (402 m.) above sea level and 53 mi. (85 km.) NNE of Rome by road. Pop. (1961) 35,748 (commune). The cathedral is 12th-century Romanesque (much rebuilt) and there are a papal palace (1283) and remains of the 13th-century walls. Rieti is linked by rail with Rome via Terni and is a road junction for Rome, Terni, and L'Aquila. Artificial textile fibres, sugar, olive oil, fertilizers, and quarrying machinery are produced. There is an experimental wheat culture station.

The ancient city was first Sabine and then Roman. From the 6th-century Lombard dukedom of Spoleto, Rieti passed to the papal states (popes often resided there) and then to Napoleon.

RIETI PROVINCE (area 1,061 sq.mi. [2,749 sq.km.]; pop. [1961] 156,630) is bounded north by the provinces of Terni, Perugia, and Ascoli Piceno; west by Viterbo; south by Rome; east by L'Aquila and Teramo. Sheep and cattle are raised; wheat, fodder, grapes, and olives are grown. The hills are thickly wooded. Terminillo, 13 mi. (21 km.) NE of Rieti, is a holiday resort. Marble is quarried at Cottanello and there is a hydroelectric power station at Cittaducale. (Ma. Ca.)

RIEVAULX, a ruined Cistercian abbey, situated in the wooded, steep-walled vale of the River Rye—whence the name—2¾ mi. (3½ km.) WNW of Helmsley, North Riding of Yorkshire, Eng. Of its church, 125 yd. (114 m.) long, built between the foundation in 1131 and *c.* 1230, the chancel and transept walls stand to full height, exhibiting some of the best English Gothic extant. The elaborate remains of this great monastery, the motherhouse for northern England of St. Bernard's mission and once ruled by Aelred (*see* AELRED, SAINT), have been well conserved by the Ministry of Works, custodian since 1918.

There is a small modern village. Along the brink of the eastern hill overlooking the abbey is Rievaulx Terrace, with two classical temples, built (1750–60) by Thomas Duncombe late in the progressive landscape adornment of his Duncombe Park estate.

RIFF: *see* ER RIF.

RIFIS (RIF, RIFF, RIFFI, RIFFIANS), Berber tribes occupying a part of northeastern Morocco known as *al-Rif,* an Arabic word meaning "edge of cultivated area." This country, with its mountains, rolling fields and deserts, is bordered to the west, east and north by the Uringa and Muluya rivers and 145 mi. of Mediterranean seacoast. To the south are tribal territories of Senhaja Berbers and Arabs (*see* BERBER).

The Rifis are divided into 19 tribes: 5 in the west along the coast, 7 in the centre, 5 in the east and 2 in the southeastern desert. One central tribe, of Targuist, is Arabic-speaking, as are the sections of the five western tribes. The others speak the Riffian tongue, a regionally variable Masmuda Berber language mutually incomprehensible with the neighbouring Senhaja dialects but grading in the east into Zenata. Many also speak Spanish and Arabic. The Rifis are Sunni Muslims; their material culture is characteristically Berber, based on cultivation, herding and sardine-seining. They are the fairest of Berbers; about two-thirds have light skins, a tenth have reddish or light hair, over half have light or mixed eyes, and there is a high frequency of stocky builds and square faces.

Before their loss of independence in 1926 (*see* MOROCCO: *The French and Spanish Protectorates*) they were organized by kinship and residence into graded units: the extended family (or vein); the endogamous clan (or bone); a multiclan territory (or fourth); and a group of contiguous fourths (or fifth). In 14 cases the tribe is itself a fifth; in 4 others (Gzennaya, Beni Urriaghel, Temsaman and Galiya) the tribe has five fifths. Unlike the simpler town-meeting structure of the Kabyle (*q.v.*) and Shluh, the complex Riffian system was representative. Each unit above the vein had a council of elected or appointed *imgharen* (sing., *amghar*), renowned fighters and masters of intrigue, one of whom, in time of war, became commander. When clans began to fight each other, their neighbours united to battle both sides at once, forcing a truce and collecting indemnities. Although internally at peace since their pacification by the French and Spanish in 1926 and the restoration of Moroccan sovereignty in 1956, thousands of Riffians, who fought many campaigns in elite French and Spanish regiments, maintained their reputation in the 1960s as one of the

world's great warrior peoples. *See* also ABD-EL-KRIM.

RIFLE. In the broadest sense of the term, a rifle is any firearm with a rifled bore, *i.e.*, with shallow spiral grooves cut in the surface of the bore to impart a spin to the bullet or projectile. The term is most often applied to small-bore weapons fired from the shoulder and used either for sport or for military service. (*See* GUNS, SPORTING AND TARGET; SMALL ARMS, MILITARY.) In military language the term also denotes larger weapons with rifled bores, such as recoilless rifles and big naval guns. Though field guns, howitzers, and machine guns have rifled bores they are not normally referred to as rifles.

The practice of rifling the bore of a weapon is old, dating back at least to the 15th century. As the earliest examples of rifled guns had straight rather than spiral grooves, it is thought the purpose of the grooves may have been to receive the powder residue or fouling that was an annoying problem with all early firearms. Gunmakers soon discovered that spiral grooves caused bullets to spin and that the spinning action increased their range and improved their accuracy. The spinning principle increased in importance when spherical lead balls were replaced by elongated bullet-shaped projectiles. The latter type of bullet rotated on its longitudinal axis in the same manner that an arrow rotated due to the angle of its feathers. Over the years, gun designers experimented with a great variety of rifling forms to achieve the best results. Most military rifles of the 20th century have four grooves with a right-hand twist of one turn in something between 10 and 20 inches.

A major difficulty with early muzzle-loading rifles was the problem of loading. As the bullet had to fit tight against the grooves, it had to be rammed down the bore with a ramrod. Rifles of the muzzle-loading era could not be loaded as rapidly as smooth-bore muskets and therefore never gained wide acceptance as military arms. With the advent during the 19th century of breech-loading repeating rifles using metallic cartridges the picture changed completely; the rifle soon replaced the musket as a military weapon. The repeating rifle that held sway during World War I was succeeded during and after World War II by the semi-automatic rifle, notably the U.S. army's Garand rifle. In the 1950s improved rifles capable of both semiautomatic and full automatic fire came into common use.

RIFT VALLEY REGION, KENYA, the largest of the seven regions of Kenya. *See* KENYA.

RIGA (Lettish RĪGA), a Baltic seaport and the capital of Latvia (the Latvian Soviet Socialist Republic, U.S.S.R.), lies on both banks of the Daugava (Western Dvina, Düna), 9 mi. (14 km.) above its mouth in the Gulf of Riga and 343 mi. (552 km.) SW of Leningrad by rail. Pop. (1959) 604,700. The centre of modern Riga is the old or inner town, bordering the right bank of the river and bounded landward by a canal, formerly part of the 17th-century Swedish fortifications (demolished 1857). This quarter, with narrow streets and churches and monuments dating from the 13th century, has preserved much of its medieval character, although during the withdrawal of Soviet troops from Riga in 1941, some of the oldest and finest buildings (*e.g.*, the Hanseatic "House of the Black Heads") were destroyed, and St. Peter's Church (begun 1209) lost its 400-ft.-high wooden tower. The Doma, or Cathedral of St. Mary (*c.* 1215), rebuilt and restored in the 16th and 19th centuries, has a notable organ; it became a museum and concert hall in 1959. The castle of the master of the Livonian Order (built 1328–40) remains largely as reconstructed by *Landmeister* Wolter von Plettenberg in 1494–1515. It served as the residence of the Swedish governors-general and as the presidential palace during Latvia's independence. On the site of the former fortifications are parks traversed by boulevards, with various public buildings, including the Latvian University (founded 1919), the Conservatory, Opera House, and National Theatre. The Vidzeme, Latgale, and Jelgava (Mitau) suburbs, respectively north- and southeast of the old town and on the left bank of the Daugava, have expanded since the mid-19th century to form the newer Riga. The resort of Rigas Jūrmala, with its broad beaches, lies southwest of the river mouth.

Riga's port (depth 23–27 ft. [7–8 m.]) has installations, including cold storage, warehouses, and a grain elevator, extending downriver to the outer ports of Vecmīlgrāvis (Mühlgraben), Bolderāja (Bolderaa), and Daugavgriva (Dünamünde). Ice-breakers are used to maintain navigation during the winter. Railway lines extend from Riga throughout the republic and to Tallinn, Kaunas, Moscow, Leningrad, and other Soviet cities. The town is an important military base and has an airport.

By the Daugava and the Gauja (Aa) went the ancient trade route of the Vikings, and from 1282 Riga was an important member of the Hanseatic League and the greatest trading centre in the Baltic. Its commercial importance declined in the 17th century although it was then the largest town in the Swedish realm. In the 19th century, after the railways were built, it was, with St. Petersburg, chief among Russian ports, and was the European centre of the timber trade. Before World War I Riga was the third-ranking industrial town in Russia, but during that war all the industry was evacuated. During the period of Latvia's independence, agriculture flourished and industry was partly renewed. After World War II factories for the production of diesel engines, turbines, transport and electrotechnical equipment, and other machinery were installed to supply the needs of the Soviet Union. Other products include paper, textiles, chemicals, glass, and cement, but the export of agricultural products has ceased. There are shipyards at Vecmīlgrāvis.

About 1190 in the camp of Livs by the Ridzene River, where Bremen merchants were already established, the monk Meinhard erected a monastery. In 1201 Bishop Albert I of Livonia removed his seat there from Ikškile (Uxküll) and obtained from Pope Innocent III extensive privileges for the city of Riga, which in 1253 became an archbishopric. At first Riga was governed by the city laws of Visby in Gotland, but later developed its own special laws. These, supplemented by the laws of Hamburg, were granted to the towns of Vidzeme, Kurzeme, and Estonia, and preserved until the Russification in 1885. In the long struggles between the archbishops and the Teutonic Order (which in 1237 absorbed the Livonian Brothers of the Sword founded by Bishop Albert in 1202), Riga often acted independently, but took part in the confederation of von Plettenberg against the attacks of the Muscovite tsar Ivan IV. In 1522 the Reformation gained ascendancy in Riga. While Vidzeme became a Polish possession in 1561, Riga remained a free city until 1581. Thereafter the Polish king Stephen Báthory promised to respect its autonomy, privileges, and the Evangelical-Lutheran religion. Gustavus II Adolphus of Sweden acted similarly on taking Riga in 1621. During the Northern War the Russian commander also accepted, in the terms of its surrender by the Swedes (1710), Riga's special position, and this was confirmed by Peter I the Great in the Treaty of Nystad in 1721. In 1812, the approach of the French being apprehended, the suburbs were burned.

During World War I Riga was occupied by German forces from Sept. 3, 1917. Following the proclamation of the Latvian Republic on Nov. 18, 1918, it became the capital of Latvia. During World War II it was first occupied by Soviet troops—being incorporated in the Soviet Union on Aug. 5, 1940—and then by the Germans until Oct. 13, 1944. (J. A. Bo.)

RIGAUD, HYACINTHE (HYACINTHE FRANÇOIS HONORAT MATHIAS PIERRE MARTYR ANDRÉ JEAN RIGAU Y ROS) (1659–1743), was one of the most prolific as well as the most successful of French portrait painters at the court of Versailles during the end of Louis XIV's reign and the beginning of Louis XV's. He was born at Perpignan on July 18, 1659, and was trained at Montpellier before moving to Lyons and finally in 1681 to Paris. Although successful in obtaining the Grand Prix de Rome, he allowed this to lapse on the advice of Jean le Brun and devoted himself to painting portraits. By 1688, when he received his first royal commission, he already had a considerable reputation among the wealthier bourgeoisie of Paris. From 1690 onward

his work, primarily for the court, consisted almost entirely of portraits. A private ambition was realized when he gained admission to the Academy as a historical painter in January 1700. He died in Paris on Dec. 29, 1743.

Rigaud excelled in the great formal portrait, and the famous portrait of 1701 of Louis XIV in robes of state (now in the Louvre) is the most distinguished example of a manner that derives primarily from Van Dyck. His more intimate manner, reserved for personal friends, reflects an interest in portraits by Rubens and Rembrandt, unusual in France at that period, and is best exemplified in the double portrait of the artist's mother, painted in 1695 in connection with the commission of a portrait bust from Antoine Coysevox, and now in the Louvre.

BIBLIOGRAPHY.—*Le Livre de raison du peintre Hyacinthe Rigaud* (ed. by J. Roman, 1924); W. Weisbach, *Französische Malerei des 17. Jahrhundert* (1932); A. Blunt, *Art and Architecture in France, 1500–1700* (1953).

RIGAUDON, a lively dance of frivolous nature in 2/2 or 4/4 time. It should properly begin (although exceptions occur) with two eighth-note upbeats on the count of 4. Most authorities believe it to be truly French, specifically a Provençal sailors' dance, deriving its name from a famous Marseilles ballet master named Rigaud who brought it to Paris around 1630. It became very popular in England as the Rigadoon. The dance itself included much running, hopping and turning; also *balancés* done with quick little jumps. The music, the melodic structure of which closely resembles that of most English hornpipes, is only occasionally found in the suite. (L. Ht.)

RIGEL, the bright star at the heel of the constellation Orion (*q.v.*). It is one of the brightest stars in the sky. Its equivalent in the alphabetical series is β Orionis. Rigel is in reality—as well as apparently—one of the brightest stars known.

Rigel is a blue supergiant located at a probable distance from the sun of between 550 and 1,100 light-years. If Rigel were as close to the sun as the bright star Sirius (nine light-years), it would shine with a brilliancy similar to that of the half-moon. *See* STAR. (W. W. M.)

RIGGING, a general term denoting the whole apparatus of masts, yards, sails and cordage of a ship. (*See* also SAILS; SEAMANSHIP; SHIP; YACHT.) The word is also used to mean cordage only. Sailing vessels are classed according to their rig; *i.e.*, the arrangement of their spars, sails and cordage. Cutter, brig and ship are really convenient abbreviations for cutter-rigged, brig-rigged and ship-rigged.

Elements of Rigging.—The basis of all rigging is the mast, which may be composed of one or many pieces of wood or steel. The mast is supported against fore and aft or athwartship strains by fore and backstays and by shrouds, known as the standing rigging, because they are made fast, and not hauled upon. The bowsprit, though it does not rise from the deck but projects from the bow, is in the nature of a mast. The masts and bowsprit support all the sails, whether they hang from yards slung across the mast; or from gaffs projecting from the mast; or, as in the case of the jibs or other triangular sails, travel on the ropes called stays, which go from the mast to the bowsprit or deck.

F. B. GRUNZWEIG—PHOTO RESEARCHERS, INC.
STANDING OR RUNNING RIGGING SHOWING MAINMAST, YARDS, AND JUNCTIONS WITH SHROUDS AND RATLINES

The bowsprit is subdivided like the masts. The bowsprit proper corresponds to the lower fore-, main- or mizzen mast. The jib boom, which is movable and projects beyond the bowsprit, corresponds to a topmast; the flying jib boom, which also is movable and projects beyond the jib boom, answers to a topgallant mast.

The ropes by which the yards, booms and sails are manipulated for trimming to the wind or for making or shortening sail are known as the running rigging. The rigging also provides the crew with the means of going aloft and for laying out on the yards to let fall or to furl the sail. The shrouds (*see* below) are utilized to form ladders, the steps of which are called ratlines. Near the heads of the lower masts are the tops—platforms on which men can stand—and in the same place on the topmasts are the crosstrees whose main function is to extend the topgallant shrouds. The yards are provided with ropes, extending from the middle to the extremities or yardarms, called footropes, which hang down about two or three feet and on which men can stand. The material of which the cordage is made varies greatly. Leather has been used, but the prevailing materials have been hemp or grass rope, chain and wire.

As the whole of the rigging is divided into standing and running, so a rope forming part of the rigging is divided into the standing part and the fall. The standing part is that which is made fast to the mast, deck or block. The fall is the loose end or part on which the crew hauls. The block is the pulley through which the rope runs. A tackle is a combination of ropes and blocks which gives increased power at the lifting or moving end, as distinct from the end being manned. If the ship in the illustration is followed from the bow to the mizzenmast, it will be seen that a succession of stays connect the masts with the hull of the ship or with one another. All pull together to resist pressure from the front. Pressure from behind is met by the backstays, which connect the topmasts and topgallant masts with the sides of the

vessel. Lateral pressure is met by the shrouds and breast backstays. A temporary or preventer backstay is used when great pressure is to be met. The bobstays hold down the bowsprit, which is likely to be lifted by the tug of the jibs and of the stays connecting it with the fore-topmast. If the bowsprit is lifted the fore-topmast loses part of its support.

The running rigging by which all spars are hoisted or lowered and sails spread or taken in may be divided into those which lift and lower—the lifts, jeers, halyards (haulyards)—and those which hold down the lower corners of the sails—the tacks and sheets. A long technical treatise would be required to name the many parts of standing and running rigging and their uses. All that is attempted here is to give the main lines and general principles or divisions.

The vessel dealt with here is the fully rigged ship with three masts. But the principles of others are the same. The simplest of all forms of rigging is the dipping lug, a quadrangular sail hanging from a yard and always hoisted on the side of the mast opposite to that on which the wind is blowing (the lee side). When the boat is to be tacked so as to bring the wind on the other side, the sail is lowered and rehoisted. One rope can serve as halyard to hoist the sail and as a stay when it is made fast on the side on which the wind is blowing. The difference between such a craft and the fully rigged ship is that between a simple organism and a very complex one; but it is one of degree, not of kind. The steps in the scale are innumerable. Every sea has its own type. Some in eastern waters are of extreme antiquity, and even in Europe vessels are still to be met with which differ very little if at all from ships of the Norsemen of the 9th and 10th centuries.

Types of Rigging.—When the finer degrees of variation are neglected, the types of rigging may be reduced to comparatively few, which may be classed by the shape of their sail and the number of their masts. At the bottom of the scale is such a craft as the Norse herring boat. This boat has one quadrangular sail suspended from a yard which is hung (or slung) by the middle to a single mast which is placed (or stepped) in the middle of the boat. She is the direct representative of the ships of the Norsemen. Her one sail is a course such as is still used on the fore- and mainmasts of a fully developed ship; a topsail may be added (above the course) and then we have the beginning of a fully clothed mast. A similar craft called a Humber keel is used in the north of England.

The lug sail is an advance on the course, since it is better adapted for sailing on the wind, with the wind on the side. When the lug is not meant to be lowered, and rehoisted on the lee side, as in the dipping lug mentioned above, it is slung at a third from the end of the yard, and is called a standing lug. A good example of the lug is the junk. As the lug is a lifting sail, and does not tend to press the vessel down as the fore-and-aft sail does, it is much used by fishing vessels in the North sea.

The type of the fore-and-aft rig is the schooner. The sails on the masts have a gaff above and a boom below. These spars have a prong called the jaws, which fit to the mast and are held in place by a jaw rope on which are threaded beads called trucks. Sails of this shape are carried by fully rigged ships on the mizzen-mast, and can be spread on the fore and main. They are then called trysails and are used only in bad weather when little sail can be carried, and are hoisted on the trysail mast, a small mast above the great one. The lateen sail, a triangular sail akin to the lug, is the prevailing type of the Mediterranean.

These original types, even when unmodified by mixture with any other, permit of large variations. The number of masts of a lugger may vary from one to five, and of a schooner from two to five or even seven. A small lug may be carried above the large one, and a gaff topsail may be added to the sails of a schooner. A one-masted fore-and-aft-rigged vessel may be a cutter or sloop. But the pure types also may be combined, in topsail schooners, brigantines, barkentines and barks, when the topsail, a quadrangular sail hanging from and fastened to a yard, slung by the middle, is combined with fore-and-aft sails. The lateen rig has been combined with the square rig to make such a rigging as the xebec, a three-masted vessel square rigged on the main, and lateen on the fore and mizzen. Triangular sails of the same type as the jibs

can be set on the stays between the masts of a fully rigged ship, and are then known as staysails. Studding sails (pronounced "stunsails") are lateral extensions to the courses, topsails, etc., of a square-rigged ship to increase the spread of sails.

Historical Development.—The development of the rigging of ships is a very obscure subject. It was the work of centuries and of practical men who wrote no treatises. It has never been universal, yet a comparison of a four-masted junk with the figures of ships on medieval seals shows much similarity. By selecting a few leading types of successive periods it is possible to follow the growth of the fully rigged ship in its main lines in modern times.

For a time, and after the use of spritsails had been given up, the spritsail yard continued to be used to discharge the function now given to the gaffs. The changes in the mizzen have an obscure history. About the middle of the 18th century it ceased to be a pure lateen. The yard was retained, but no sail was set on the fore part of the yard. Then the yard was given up and replaced by a gaff. The resulting new sail was called the spanker. It was, however, comparatively narrow, and when a greater spread of sail was required, a studding sail (at first called a driver) was added, with a boom at its foot. At a later date "spanker" and "driver" were used as synonymous terms, and the studding sail was called a "ringtail." The studding sails are the representatives of a class of sail once more generally used.

In modern times a sail is cut of the largest size that can be carried in fine weather, and when the wind increases in strength it is reefed; *i.e.*, part is gathered up and fastened by reef points, small cords attached to the sail. Till the 17th century at least the method was often to cut the courses small, so that they could be carried in rough weather. When a greater spread of sail was required, a piece called a bonnet was added to the foot of the sail, and a further piece called a drabbler could be added to that. An example of the tenacious conservatism of the sea is seen in the retaining of this practice by the Swedish small craft called *lodjor* in the Baltic and White seas. It will be easily understood that no innovation was universally accepted at once. Jib and sprit topsail, lateen-mizzen and spanker, and so forth, would be found for long on the sea together.

The history of the development of rigging is one of adjustment. The size of the masts had to be adapted to the ship, and it was necessary to find the proper proportion between yards and masts. As the size of the medieval ship increased, the natural course was to increase the height of the mast and of the sail it carried. Even when the mast was subdivided into lower, top and topgallant, the lower mast was too long, and the strain of the sail racked the hull. Hence the constant tendency of the ships to leak. Sir Henry Manwayring, when giving the proper proportions of the masts, says that the Flemings (*i.e.*, the Dutch) made them taller than the English but were forced to make the sails less wide.

A few words may be added concerning the tops. In the earlier form of ship the top was a species of crow's-nest placed at the head of the mast to hold a lookout, or in military operations to give a place of advantage to archers and slingers. Tops appeared occasionally as mere bags attached to one side of the mast. As a general rule they were round. In the 16th century there were frequently two tops on the fore- and mainmasts, one at the head of the lower, another at the head of the topmast, where in later times there have been only the two traverse beams which make the cross-trees. The upper top dropped out by the 17th century. The form was round, and so continued until the 18th century when the quadrangular form was introduced.

Power Ships.—Steam and motor ships still carry one or more masts for supporting derricks, for lifting heavy weights in and out of the ship, for carrying wireless antennas, for providing a platform for lookout aloft, for mounting the steaming lights and for visual signaling. In the bigger ships the masts are usually hollow steel structures, occasionally with an internal ladderway, while in some merchant ships they also act as uptake ventilators. Stays are usually provided on the same principle as in sailing days, but dead-eyes have given way to bottle screws as rope has to wire. Where masts are provided with ladderways, either internally or externally on the iron structure itself, ratlines on the rigging are dispensed with. Modern battleships, battle cruisers and light cruisers in the Royal Navy usually have a tripod foremast in which the lower mast is supported by two inclined steel struts instead of rigging. This is to give the necessary rigidity for mounting the gun director and range finder (*see* GUNNERY, NAVAL).

The main mast usually carries the main derrick and is stayed on the old lines. Wooden topmasts and sometimes topgallant masts are fitted for wireless and signaling, while one or more signal yards are always carried on the foremast. In light cruisers the main mast is usually a small wooden pole. Destroyers and other light craft are fitted with a light wooden foremast and usually a short main or mizzen mast.

The upper end of the standing rigging is shackled to steel bands round the lower masthead. The lower ends are secured to the deck by bottle screws and slips, the screw being locked by a check piece which prevents its easing back; together with its slip it is covered with painted canvas.

The topmast rigging, consisting of the usual shrouds, stays and backstays, is fitted with insulators to avoid interference with radio and danger from lightning. A Jacob's ladder gives access to the masthead, while above all is a lightning conductor connected by a copper strap running down the mast to the hull of the ship. Where a masthead flashing lamp is fitted, a gallows is provided for its reception. In flagships a pole 16 ft. long is clamped to the fore topmast or fore topgallant masthead to carry the admiral's flag. Clothes lines and hammock gantlines (used for drying clothes and hammocks) are of thin flexible steel rope in warships. They lead through blocks on a shroud near the fore or main lower mastheads and are set up well forward or well aft.

Dressing lines lead from the foremast awning stantion over both topmasts and down to the after awning stantion. To these are attached flags for dressing ship.

Signal halyards, made of light white line, lead through blocks

RIGHT ASCENSION, in astronomy, the co-ordinate on the celestial sphere analogous to longitude on the earth. It is the angle at the celestial pole reckoned eastward from the hour circle through the vernal equinox to the one through the body in question, or the arc of the celestial equator measured eastward from the vernal equinox to the foot of the object's hour circle. (An hour circle is a great circle passing through the celestial poles, perpendicular to the equator). The one through the vernal equinox, the origin for this measurement, takes the place of the Greenwich meridian in earth geography. Right ascension is expressed in time more often than in angular units, and is measured entirely around the equator, having any value from 0 hours to 24 hours, or 0° to 360° (15° is equivalent to 1 hour, and 1° to 4 minutes of time). The common abbreviation is the Greek letter α.

(H. M. Lo.)

RIGHTS OF MAN AND OF THE CITIZEN, DECLARATION OF, one of the basic charters of human liberties, was a philosophical preamble to the French Constitution of Sept. 3, 1791, expounding the principles that inspired the French Revolution. The Constituent Assembly adopted the outline of the declaration on Aug. 4, 1789, and approved the text on Aug. 26. Louis XVI accepted it on Oct. 5, 1789, during the riots which forced him the next day to leave Versailles for Paris.

The declaration was derived from the constitutions of certain North American states, such as Virginia and New Hampshire. Its notion of the separation of powers came from Montesquieu, its doctrine of natural rights from the *Encyclopédie* and John Locke, its theory of the general will and of the sovereignty of the nation from Jean Jacques Rousseau. From Voltaire came the idea that the individual must be safeguarded against arbitrary police or judicial action and from the Physiocrats the doctrine of the inviolability of private property. The whole declaration is characteristic of 18th-century French thought, which strove, before making practical rules, to isolate and specify principles which are fundamental to man and therefore universally applicable.

The declaration, omitting any reference to God (except, in the preamble, by the non-Christian designation "Supreme Being"), to the king (although the constitution provided for the retention of the monarchy), or to tradition, the three cornerstones on which the French state had hitherto rested, announced society to be an association of "free and equal" individuals, united "for the protection of their natural rights." It recognized the sovereignty of the nation and the existence of the general will, but carefully limited the authority of the law to ensure that it should not crush the individual, who confronted the state alone (no right of association being recognized). The right to private property was strongly affirmed, both against communistic theories and against the crown's claim to dispose of subjects' property. The 17 articles comprising the declaration are as follows:

1. All men are born and remain free, and have equal rights. Social distinctions are unjustifiable except insofar as they may serve the common good.

2. The purpose of political association is to preserve the natural and inalienable rights of man, *i.e.*, liberty, private property, the inviolability of the person, and the right to resist oppression.

3. Sovereignty resides essentially in the nation as a whole; no group or individual can exercise any authority not expressly delegated to it or him.

4. Liberty is the right to do anything which does not harm others. Thus, each man's natural rights are limited only by the necessity to assure equal liberty to others. Only the law can determine what restrictions must be made.

5. The law can proscribe only those actions which harm society. Any action not forbidden by law cannot be disallowed, nor can anyone be forced to do what the law does not specifically command.

6. Law is the overt expression of the general will. All citizens have the right to participate in legislation, either in person or through their representatives. The law must be framed to operate completely impartially. Since all are equal before the law, all are equally eligible, in accordance with their abilities, for all public offices and positions.

7. No man can be indicted, arrested, or held in custody except for offenses legally defined, and according to specified procedures. Those who solicit, transmit, execute or cause to be executed arbitrary commands must be punished; but if a citizen is summoned or arrested in due legal form it is his duty to obey instantly.

8. The law must impose only penalties that are obviously necessary. No one can be punished except under the correct application of an established law which must, moreover, have existed before he committed the offense.

9. Everyone must be presumed innocent until he is pronounced guilty. If his arrest and detention are thought necessary, then no more force may be used than is necessary to secure his person.

10. No one must suffer for his opinions, even for religious opinions, provided that his advocacy of them does not endanger public order.

11. Free communication of thought and opinion is one of the most valuable rights of man; thus, every citizen may speak, write, and print his views freely, provided only that he accepts the bounds of this freedom established by law.

12. Some form of military or police force is necessary to guarantee the maintenance of the rights of man and of the citizen; thus, such a force exists for the benefit of all and not for the particular ends of those who command it.

13. To maintain the police force and to meet administrative expenses a financial levy is essential; this must be borne equally by all citizens, in accordance with their individual means.

14. All citizens have the right to decide, either personally or through their representative, the necessity of a financial levy and their free assent to it must be obtained. They can appropriate it, and decide its extent, duration, and assessment.

15. Society has the right to require of every public official an account of his administration.

16. A society in which rights are not guaranteed, and in which there is no separation of powers, has no constitution.

17. Since the right to private property is sacred and inviolable, no one can be deprived of it except in certain cases legally determined to be essential for public security; in such cases a fair indemnity must first of all be granted.

(CL. H.)

RIGORISM, in general, means stern attachment to a rule, as in asceticism or monasticism (*qq.v.*). In the 18th century, however, the term was applied in particular to the practice of those moral theologians who insisted on the strictest interpretation of the laws of God and of the church in cases of conscience (*see* CASUISTRY). The Jansenists, especially, were described as rigorist in their opposition to probabilism (*q.v.*). In philosophical ethics, Kant took the term to describe a system of morality based on reason alone, without any appeal to hedonism.

RIIS, JACOB AUGUST (1849–1914), U.S. newspaper reporter and social reformer who shocked the nation's conscience in 1890 by factual description of slum conditions in his book *How the Other Half Lives.* He was born on May 3, 1849, at Ribe, Den., and emigrated to the United States at the age of 21. For the next three years he went from job to job, gaining a first-hand acquaintance with the ragged underside of city life. In 1873 the chance offer of a newspaper job started him on his life's work. Riis became a police reporter, assigned to New York City's lower East Side, where he found that in some tenements the infant death rate was one in ten. Riis employed the newly invented flashbulb technique to take photographs of the rooms and hallways of these buildings to dramatize his lectures and books.

How the Other Half Lives made Riis famous. A typical response to it was that of the future president of the United States Theodore Roosevelt, who called at the reporter's office and left

his card with the message: "I have read your book, and I have come to help." The book stimulated the first significant New York legislation to curb tenement house evils. Of Riis' many other books, which dealt largely with slum problems, the most noteworthy was his autobiography, *The Making of an American* (1901). His writing foreshadowed the muckraking literature of the years 1900–14 (*see* MUCKRAKERS). His death at Barre, Mass., on May 26, 1914, helped to mark the passing of a great era of reform in American life.

RIJEKA (Italian FIUME), a port of Yugoslavia on the Gulf of Kvarner (Quarnero), 120 mi. (193 km.) WSW of Zagreb by road. Pop. (1961) 100,989. Rijeka has two parts: the old town is built on a ridge of the karst, while the newer quarters together with the harbour are crowded into the amphitheatre between the ridge and the shore. The terrain for the new section of the town was obtained by reclaiming marshland. The modern name of the city dates from the 13th century and referred to the river called Recina in Serbo-Croatian, Fiumara or Eneo in Italian. This river separates the town from the suburb of Susak.

The old town has a 3rd-century Roman triumphal arch, and was known in ancient times as Tarsatica. Captured by Charlemagne, the town long remained under the Franks; later it was held by the bishop of Pola. The counts of Duino held it from 1139 and in 1377 the Cathedral of the Assumption was founded. In the Renaissance period a Franciscan monastery 500 ft. (150 m.) high was built in the old town. Rijeka was next held by the counts of Frankopan. In 1466 it was incorporated into Austria. It was made a free port in 1723, united to Croatia in 1776, and declared a *corpus separatum* of the Hungarian crown in 1779. The French held it from 1809 to 1813 when the English took it. Restored to Austria in 1814 it passed to Hungary in 1822; it was Croatian from 1848 to 1870 and thereafter under Hungarian rule until World War I. In 1851 there were 12,598 inhabitants, over 11,000 of whom were Croats. The Croat political leaders passed a resolution there in 1905, known as Rijecka Rezolucija, an action program which included a call for the union of Dalmatia with Croatia.

Rijeka became a controversial issue after World War I. Although the secret Treaty of London (April 26, 1915) had assigned Rijeka to Yugoslavia, the Italians claimed it at the Paris Peace Conference on the principle of self-determination. Ignoring the suburb of Susak, which had 11,000 Yugoslavs and 1,500 Italians, they claimed that the rest of Rijeka had 22,488 Italians against 13,351 Yugoslavs and certain others. On Sept. 12, 1919, Gabriele D'Annunzio (*q.v.*), who had mustered a body of men at Ronchi near Trieste, occupied Rijeka and proclaimed himself the "commandant" of the "Reggenza Italiana del Carnaro." The Italian government, however, on concluding the Treaty of Rapallo (Nov. 12, 1920) with Yugoslavia, resolved to turn D'Annunzio out of Rijeka. Giovanni Giolitti, the premier, ordered the battleship "Andrea Doria" to shell D'Annunzio's palace only, predicting that the surprise would cause the "commandant" to escape at once—as indeed it did. Riccardo Zanella, who then took office, representing the Autonomist Party, as opposed to the Italian Nationalist, supported Count Carlo Sforza's solution of the problem, namely a free state of Fiume-Rijeka with an Italo-Fiuman-Yugoslav consortium for the port; and such a solution was approved by the Fiuman electorate on April 24, 1921. But when the Fascists gained power in Italy the Rapallo plan for a free state came to nothing. Pressed by Benito Mussolini, the Yugoslav government yielded and a new Italo-Yugoslav treaty, signed in Rome on Jan. 27, 1924, recognized Rijeka itself as Italian while Susak became Yugoslav. As Italy was unable to maintain three ports in the northern Adriatic (Trieste, Pula, and Rijeka-Fiume), Rijeka-Fiume's traffic declined. The port handled only 770,000 metric tons of merchandise in 1938 as compared with 2,100,000 metric tons in 1913.

In World War II, Rijeka was occupied by the Germans in September 1943. On May 3, 1945, after two weeks' fighting, the Yugoslavs occupied the town, the Germans having blown up the port installations. By the Treaty of Paris (Feb. 10, 1947) Rijeka became part of Yugoslavia. The port was rebuilt and by 1949 its sea traffic again exceeded 2,000,000 tons. (K. SM.; V. DE.)

RIJSWIJK, a town in the province of South Holland, Neth., lies on the southeastern outskirts of The Hague and is traversed by the Rotterdam highway and the Vliet River. Pop. (1960) 35,581. The Reformed Church dates from the 14th century and there are some 17th-century houses. The town is mainly residential but there are oil wells and scientific laboratories, and the fruit auction market is important. Nearby is IJpenburg airfield. Rijswijk is famous in history for the treaty signed there in 1697 ending the War of the Grand Alliance (*see* RIJSWIJK, TREATIES OF). (C. V. V.)

RIJSWIJK, TREATIES OF (1697), the agreements terminating the War of the Grand Alliance (*see* GRAND ALLIANCE, WAR OF THE). Largely because Louis XIV of France wanted peace in order to be free to exploit the question of the Spanish succession, a congress opened at Rijswijk, near The Hague, on May 9, 1697. Matters between France and the Maritime Powers (Great Britain and the United Provinces of the Netherlands) were settled quite smoothly, and the French capture of Barcelona induced Spain to participate. By treaties signed with the Dutch, with the British, and with the Spaniards in the night of Sept. 20–21, France repealed the tariff on Dutch goods and the embargo on Dutch salted herring; recognized William III of Orange as king of Great Britain and agreed to a restoration of the *status quo* in the principality of Orange and in the French and British colonies; and retroceded Catalonia, Luxembourg, and some places in the southern Netherlands to Spain. It was also arranged that the Dutch should garrison a chain of fortresses in the Spanish Netherlands (*see* BARRIER TREATY). Against the Holy Roman emperor Leopold I, however, France's attitude had stiffened, with the determination to keep Strasbourg and the rest of Alsace. Finally, on Oct. 30, on the expiry of a French ultimatum, Leopold accepted Louis XIV's offers: the lands east of the Rhine which France had annexed under the policy of "reunions" were given back to the Empire; Lorraine was restored to its duke, Leopold Joseph; the Palatinate was assigned to the House of Neuburg, with the last-minute stipulation that Catholicism was to be maintained there; and Leopold's protégé, Joseph Clement of Bavaria, was acknowledged as archbishop-elector of Cologne.

RILEY, JAMES WHITCOMB (1849–1916), U.S. poet famous for nostalgic dialect verse, was born in Greenfield, Ind., on Oct. 7, 1849. "The poet of the common people," Riley was elected to the American Academy of Arts and Letters, received the gold medal of the National Institute of Arts and Letters and was given several honorary degrees. His boyhood experience as an itinerant sign painter, entertainer and assistant to patent-medicine venders gave him the opportunity to compose songs and dramatic skits, to gain skill as an actor and to come into intimate touch with the rural folk of Indiana. His first reputation was gained by the series in Hoosier dialect ostensibly written by a farmer, "Benj. F. Johnson, of Boone," contributed to the *Indianapolis Daily Journal* and later published as *The Old Swimmin' Hole and 'Leven More Poems* (1883). Riley was briefly local editor of the *Anderson* (Ind.) *Democrat*, but his later life was spent in Indianapolis, where he died on July 22, 1916. Among Riley's numerous volumes are: *Pipes o' Pan at Zekesbury* (1888), *Old-Fashioned Roses* (1888), *The Flying Islands of the Night* (1891), *A Child-World* (1896), and *Home Folks* (1900). The best collected edition is the memorial edition of his *Complete Works*, 10 volumes (1916).

RILKE, RAINER MARIA (1875–1926), the greatest of modern German poets and the most internationally read, was born in Prague on Dec. 4, 1875, the only surviving child of German-speaking and German-descended parents, who separated when he was nine years old. After a lonely and abnormal upbringing (his mother, pretending that he was the daughter who had died in infancy, dressed him as a girl) he was sent (September 1886 to June 1891) to the military schools of St. Pölten and Mährisch-Weisskirchen. Rilke suffered at these schools, where he learned

little and made no friends, and from which he was finally removed on grounds of ill-health. After a year at the Commercial Academy in Linz he joined his father in Prague and enrolled as a student of law at the university, although he had already resolved to be a writer. In 1896 he left the University of Prague for that of Munich, and in October 1897 he enrolled at the University of Berlin. During these years he wrote incessantly, both in prose and verse, engaging in all kinds of literary activities, to prove, as he said later, that he could make a success of his chosen career.

THE BETTMANN ARCHIVE INC.

RAINER MARIA RILKE, PHOTOGRAPHED IN 1925

His early verse is fluent, imitative (especially of Heine), and, for the most part, evocative of vaguely "poetic" moods and attitudes. His prose tales are more objective and naturalistic, and reveal a keen eye for the individuality of people and things. Especially notable is the short, semiautobiographical *Ewald Tragy* (written *c.* 1898, published 1927–28), which evokes the stifling conventionality of the family circle in Prague. He accepted the tradition (later proved to be without foundation) that his father's family was descended from an ancient and noble one in Carinthia, and in his attempt to transform himself into the kind of person and poet he wanted to be, there is a remarkable affinity between Rilke and W. B. Yeats and his doctrine of the "anti-self." Much of the best poetry of both was largely generated by inner tensions and contradictions.

It was in Munich, in May 1897, that he met Lou Andreas-Salomé (1861–1937), a remarkable woman older than himself, to whom he became passionately attracted, who exerted a decisive influence upon him, and to whom he continued, from time to time, to turn for counsel until the end of his life. She had been born in Russia and encouraged Rilke, who had moved to Berlin, where she and her husband lived, to learn Russian and to study Russian literature. In the spring of 1899 he paid his first visit to Russia with her and her husband. Later he declared that he experienced there for the first time something like a feeling of being at home and of belonging. In the following autumn, in a sudden and unexpected fit of continuous inspiration, he wrote the first part of what eventually became *Das Stunden-Buch* (*The Book of Hours*), *Das Buch vom mönchischen Leben* (*The Book of the Monastic Life*), a series of 67 short verse meditations, supposedly those of a Russian monk, on God, nature, and human life. In these, Rilke's experience of Russia has coalesced with the scarcely less liberating experience of a long stay in Florence during the spring of 1898, when he had basked in what seemed to him the "life-enhancing" this-worldliness of Italian Renaissance art. Art as a discovery and revelation of the mystery and wonder of life, poets and painters as the true revealers and, in a sense, creators, of God—it was with this Blake-like conviction that "the whole business of man was the arts" that Rilke escaped from the sentimental and overparaded Catholicism of his mother and of his own early years. This was the characteristically modified manner in which he accepted that Nietzschean life worship and insistence on this-worldliness in which too many of his contemporaries found release; for in his conception both of life and of art and of his mission as a poet there remained always a religiousness which, however much it may differ from true religion, can be neither explained away nor identified with mere aestheticism.

From May to August 1900, he paid a second visit to Russia, this time with Lou Andreas-Salomé alone, and on his return accepted an invitation to stay with a friend in the artists' colony of Worpswede, a remote heath village near Bremen. There, in April 1901, he married the young sculptress Clara Westhoff, a pupil of Rodin's, settled down in a peasant's cottage in the neighbouring hamlet of Westerwede, and in September 1901 wrote *Das Buch von der Pilgerschaft* (*The Book of Pilgrimage*), the second part of his *Book of Hours*, full of his memories of Russia. A daughter was born, but soon Rilke and his wife decided that they must pursue their careers separately; so they broke up their household, entrusting the child to Clara's parents. Rilke had received from a German publisher a commission to write a book on Rodin, and in August 1902 he departed for Paris to meet Rodin, for whom he already felt the reverence of a disciple.

Paris, with many long absences (in Capri, 1907; Germany, Austria, Italy, Algeria, Tunis, Egypt, 1910–11; Spain, 1912–13), remained his headquarters until the outbreak of war in 1914. His first letters are full of admiration for Rodin and terrified recoil from the miseries, cruelty, and indifference of the city. In March 1903 he escaped for a month to Viareggio, and there wrote the third and last part of his *Book of Hours*, *Das Buch von der Armut und vom Tode* (*The Book of Poverty and of Death*). *The Book of Hours*, eventually published in 1905, is the first of Rilke's really unneglectable books. It is also the one in which his overwhelming tendency to subjectivity, reverie, and rhapsody, which he later so successfully corrected, finds its most uninhibited expression. The poems in all three parts are essentially outpourings, with a play of imagery and a rhythmical energy by which most readers are irresistibly swept along. Rilke regarded them as improvisations; on the other hand, long after his conception of what a poem should be had become far more exacting, he often wished he could reachieve something like the inspired and exalted mood in and out of which they had been written.

In July 1902 he had published *Das Buch der Bilder* (*The Book of Images*), containing Neoromantic poems written between 1898 and 1901, with a peculiar combination of the descriptive, the evocative, and the symbolic, but still with "poetic" treatments of "poetic" subjects and moods: among the 37 added to the second edition (1906) are several which are very beautiful. But now, under the influence of Rodin and of French poets such as Baudelaire, he tried to achieve something altogether different—to work regularly, as in front of a model, like a sculptor or painter. The result was the two parts (1907, dedicated to Rodin, and 1908) of *Neue Gedichte* (*New Poems*), that astonishing combination of German "inwardness" and French elegance and objectivity. Essentially all these poems are *Dinggedichte* (poems of "things"), even when they evoke human beings. Cathedrals and statues, palaces and parks, fountains, pavilions, and staircases; dolphins, panthers, flamingos, and gazelles; hydrangeas, heliotropes, poppies, and roses; young girls and lovers, the beggars and the blind—Rilke seems to have entered into them all and to speak for them rather than of them. There is magic in the "things" presented, steeped in their own atmosphere and most of them impregnated with the sense of the past. In his interpretation of the legends of Alcestis, of Orpheus and Eurydice, in other poems in these collections, and in the contemporary requiems, he voiced that absorption with the problem of death which was a lifelong preoccupation.

Much of the subjectivity and *Angst* which he was able to keep out of *New Poems* found its way into his remarkable prose work *Die Aufzeichnungen des Malte Laurids Brigge* (*The Notebooks of Malte Laurids Brigge*), begun at Rome in 1904, continued mainly in Paris, and published in 1910. This study of the dark side of existence and the night side of the mind reveals the mental and spiritual terrors which the young Danish hero undergoes in Paris, and the agonies of fear he lived through in his childhood. It is confessional in much the same way as Goethe's *Werther;* but, unlike Goethe, Rilke could not exorcise the horrors which haunted him.

For a time he seems to have contemplated yet a third part of *New Poems*, but he came to recognize that his next task would be the writing of a kind of poetry which, in a very special sense, would have to be lived before it could be written; for he must first achieve and then communicate some vision, of what might be called the value and destiny of the individual. During a solitary sojourn at Schloss Duino on the Adriatic near Trieste, placed at his disposal by his friend and benefactress Princess Marie von Thurn und Taxis-Hohenlohe (November 1911–May 1912), a type of inspiration, different in kind from anything he had so far ex-

perienced, seized upon him and dictated the first two poems of the cycle which was finally completed in 1922 and called *Duineser Elegien* (*Duino Elegies*). During the ten years between its inception and its consummation Rilke lived in a state of suspension, waiting, working, and hoping for the miracle of Duino to recur.

When war broke out he was in Germany and, strangely uplifted by the greatness of the calamity, he composed five magnificent hymns addressed to the god of war. Hölderlin's influence is discernible in the apocalyptic quality of the style of these and one or two other poems of the period. But the rising tide of inspiration was checked by the mental suffering the war induced, aggravated by Rilke's short period of war service (November 1915–June 1916), for a few weeks in the infantry of the second reserve and then for a few months as a clerk in the war ministry in Vienna. This was a kind of sinecure, but it increased the poet's hopelessness and apathy, which were hardly lessened by the many friends he made in Munich where he spent most of the war years. In 1919 he accepted an invitation to Switzerland to give readings of his poems; there he remained until his death, undertaking short visits to Venice and Paris, but never returning to Germany or Austria.

The third Duino elegy was completed in Paris in 1913 and the fourth was written in Munich in 1915; but it was not until February 1922, during about 18 days of tumultuous inspiration, in the little Château de Muzot, at Raron near Sierre in the Swiss canton of Valais, his final refuge and home, that he was able to complete the cycle of ten. About the power of these poems there can be no doubt; how far the situations and problems they evoke are those of humanity in general, and how far those of the solitary and almost religiously dedicated poet himself can be questioned.

The completion of the *Duino Elegies* in February 1922 was both preceded and followed in the same burst of inspiration by the composition of the 55 entirely unexpected *Sonette an Orpheus* (*Sonnets to Orpheus*). In these, as in many of the other poems which Rilke wrote during the remaining four years of his life, we may perceive the emergence of something new: of a mood (the reward, perhaps, of much patient endurance of silence, terror, and perplexity) of joyful acquiescence and celebration.

Rilke died at the Château de Muzot on Dec. 29, 1926, from acute leukemia, from which he seems to have been suffering since 1923, but which was diagnosed only shortly before his death.

The international fame to which Rilke attained in his lifetime has continued to increase after his death, as the innumerable memoirs, monographs, commentaries, biographies, and translations in many European languages bear witness. His voluminous correspondence constitutes both a literary and a psychological phenomenon of absorbing interest. Some letters read like literary essays of a descriptive or reflective nature; others contain first sketches or rough drafts of poems to come; passages from letters to his wife and to Lou Andreas-Salomé were later used almost *verbatim* in *Malte Laurids Brigge;* there are confessional outpourings, and elaborate essays in self-portraiture and self-exegesis.

Rilke's poetical reputation achieved its summit with the *Duino Elegies* and the *Sonnets to Orpheus.* The mysterious philosophical undertow of the elegies and the sonnets with its doctrinal implications creates that impression of something greater than art which great works of art produce. The cosmic isolation of man facing the glorious, austere, aloof, and indifferent angels of the elegies, the tragic nature of his attempts to transcend mortality by love as he journeys irrevocably deathward, the summons received by the poet toward the end of the elegies to justify his existence by transforming the visible world into visible art—all this, expressed with visionary intensity, embodies an appeal or a message to humanity which also pervades the sonnets. Some of these practice the doctrine they preach by magically transforming objects, already half-dematerialized in *New Poems,* into sound so pure that only their vibrations seem to linger in the air.

RIMBAUD, (JEAN NICOLAS) ARTHUR (1854–1891), French poet and adventurer, who, although his creative life lasted only from his 15th to his 20th year, became, unbeknown to himself, one of the masters of the Symbolist movement. When he abandoned literature he became first a wanderer and eventually a trader, gunrunner, and explorer in Abyssinia. He was born at Charleville in the Ardennes on Oct. 20, 1854, the second son of an army captain and a local farmer's daughter: his brother was a year older and there were two younger sisters. In 1860 Captain Rimbaud and his wife separated, and the children were brought up by their mother, who hoped to keep her sons from following the example of her two wastrel brothers. Arthur, who early displayed unusual intellectual ability, showed a gift for writing at the age of eight. Later he was the most brilliant pupil at the Collège de Charleville. He had a particular talent for Latin verse and in August 1870 won the first prize for a Latin poem at the Concours Académique. His first published poem had appeared in January 1870 in *La Revue pour tous,* and in April he had submitted to Théodore de Banville (*q.v.*), one of the selection committee for *Le Parnasse contemporain,* a number of poems including one entitled *Credo in Unam,* which, although derivative, showed signs of an original genius.

GIRAUDON

ARTHUR RIMBAUD, DETAIL FROM A PORTRAIT PAINTED BY FANTIN-LATOUR, 1872

The outbreak of the Franco-German War (July 1870) ended his formal education. In August he ran away to Paris, but was arrested for traveling without a ticket and spent some days in prison. His friend and schoolmaster, Georges Izambard, paid his fine and had him sent to Douai, where he spent three weeks at the house of Izambard's aunts, and where he joined the national guard. Izambard then took him home but in October he disappeared again, wandering through northern France and Belgium in the wake of the invading armies. Again he arrived at Douai, where he made fair copies of the poems composed during his two weeks of freedom, hunger, and rough living. These express an innocent joy in life and liberty, and are his first wholly original works.

His mother had him brought back by the police, but in February 1871 he sold his watch and again went to Paris, where for a fortnight he lived in great poverty. Then, in early March, he returned home on foot, a completely changed character, perhaps as a result of some shattering, yet enlightening, experience. He repudiated his early verses as false and wrote some of his most violent and blasphemous poems, expressing a disgust at life, a desire to escape into a world of innocence, and a sense of struggle between good and evil. His behaviour matched his poetic mood—he refused to work, and spent his days drinking in cafés, in conscious revolt against religion, morality, and every kind of discipline. At the same time he read books on occult philosophy, Cabalism, magic, and alchemy, and formulated his new aesthetic doctrine, expressed in two letters, to Izambard and to Paul Démeny (May 13 and 15, 1871), later called *Lettres du Voyant*. This is based on the belief that the poet must become a seer, a *"voyant,"* who can penetrate infinity, and, who, by breaking down the restraints and controls which make up the conventional conception of individual personality, must become the instrument for the voice of the Eternal. But because the new visions cannot be rendered in contemporary forms, a new language must be invented, a language accessible to all the senses in one—this is the ideal of "total art" first formulated by Charles Baudelaire and adopted by the Symbolists (*q.v.*).

At the end of August 1871, on the advice of a literary friend in Charleville, Rimbaud sent to Paul Verlaine (*q.v.*) specimens of his new poetry, among them "Sonnet des voyelles," in which he attributes to each vowel a different colour—"A noir, E blanc, I rouge, U vert, O bleu." The poem has been variously interpreted, but its true beauty lies in the originality of its images. Verlaine, impressed by the brilliance of the poems, summoned Rimbaud to Paris and sent the money for his fare. In a burst of self-confidence, Rimbaud composed *Le Bateau ivre*. Although traditional in versification, it is a poem of astonishing verbal virtuosity, and of daring choice of images and metaphors, inspired by a deep emotional and spiritual experience. In this masterpiece, Rimbaud reached one of the highest peaks of his art.

Arriving in Paris in September 1871, he stayed for three months with the Verlaines, who were living with Mathilde Verlaine's parents, and met most of the well-known poets of the day, but antagonized them all—except Verlaine himself—by his arrogance, boorishness, and obscenity. Requested to leave, he lived for some weeks in destitution, and then in an attic in the house where Banville was living. Again his behaviour caused complaints and in January 1872 he moved to a room where he lived, on money subscribed by Verlaine and his friends, a life of drink and debauch, and was involved in a homosexual relationship with the older poet which gave rise to scandal. In March he returned to Charleville so that Verlaine could attempt a reconciliation with his wife, but was recalled in May by his friend who vowed he could not live without him.

During this period (September 1871–July 1872), Rimbaud composed the last of his poems in verse which show an advance in technical freedom and originality on those written earlier. This freedom is daring for that period, then at the height of the Parnassian movement (*see* PARNASSIANS). At this time he also composed the work which Verlaine called his masterpiece, *La Chasse spirituelle*, the manuscript of which disappeared when Verlaine and Rimbaud went to England. Some critics also date from this creative period the transcendental prose poems which form part of *Illuminations*.

In July 1872 Verlaine abandoned his wife and fled with Rimbaud via Belgium to London, where they lived in Soho. Rimbaud may there have composed some of *Illuminations*. He returned home for Christmas but was recalled (January 1873) by Verlaine who dramatized an illness to play on his sympathy. In April Rimbaud went to the farm at Roche, near Charleville, where his mother and sisters were staying, and began to write what he called his "Livre Païen ou Nègre" which eventually became *Une Saison en Enfer*. Verlaine was meanwhile staying at Jehonville, near Roche, and in May he persuaded Rimbaud to accompany him to London. Rimbaud's sense of guilt at yielding to an influence from which he had wished to escape caused him to treat Verlaine with sadistic cruelty, varied by remorseful kindness. Finally, at the end of June, after one of their frequent quarrels, Verlaine abandoned Rimbaud and went to Belgium. Failing, however, to effect a reconciliation with his wife, he sent for Rimbaud and begged him to return with him to London. When Rimbaud tried to leave, Verlaine shot at him, wounding him in the wrist, and threatened to do so again. Rimbaud, terrified, asked a policeman for protection; Verlaine was arrested, imprisoned, and later sentenced to two years' imprisonment. After a week in hospital Rimbaud returned to Roche. There he finished *Une Saison en Enfer*, an account of his spiritual descent into Hell, and of his failure in art and love, which acquired some of its tragic character from the events in Brussels. It was printed in Belgium and, in October 1873, he went to Brussels to collect the copies, and then to Paris to arrange for its publicity. Discouraged by its reception there, he abandoned the whole edition and, returning on foot to Charleville, it is alleged that he burned his manuscripts and papers. The bales of the book remained in the attics of the printers where they were discovered in 1901, by the Belgian bibliophile Losseau. He, out of consideration for his fellow bibliophiles, who possessed the only copies known to exist, did not make his discovery public until 1915.

In February 1874 Rimbaud returned to London with Germain Nouveau, a wild bohemian poet. There they earned a precarious living in menial employment: Rimbaud may also have been composing some of *Illuminations*. Nouveau returned to Paris in June and Rimbaud seems to have fallen ill, or to have suffered acutely from poverty, for his mother and elder sister went over to help him to find a job. At the end of July he took up a post at a coaching establishment at Reading, but went home for Christmas, never to return.

In January 1875, he went to Stuttgart to learn German—his interest then was in languages. There he was visited by Verlaine, but this, their last meeting, ended in a violent quarrel. It was probably then that Rimbaud gave Verlaine the manuscript of *Illuminations*. In May he left for Italy, crossing the Alps on foot, but, taken ill with sunstroke, was repatriated by the French consul at Leghorn. He spent the winter at home, learning Arabic, Hindustani, and Russian, and, in April 1876, set out for Russia, but, after being robbed of money and luggage in Vienna, was arrested as a beggar and again sent home. In May he went to Holland, where he enlisted in the Dutch colonial army. He arrived at Batavia on July 23, but deserted on Aug. 15 and eventually reached home at the end of December. In the spring of 1877 he went to Hamburg, and, failing to find work on a ship sailing east, he is said to have joined a circus going to Scandinavia, but returned to France in the summer. In the autumn, however, he set out for Alexandria, but, taken ill on board ship, was landed in Italy, and again returned home. There he remained, enfeebled by illness, until October 1878, when he set off for Egypt. He took a boat from Genoa to Alexandria and then went to Cyprus, where he worked as a labourer, but in June 1879, he fell ill with typhoid fever and returned home to recover.

It was during this winter of illness that he apparently decided to abandon his life of wandering and to plan for the future. Returning to Cyprus in the spring he found work as a builder's foreman but, in August, he quarreled with his employers and set out in search of work. A coffee exporter at Aden, Pierre Bardey, sent him to open a trading post at Harar, in the interior, at that time occupied by the Egyptians, but, after the Mahdi rising in the Sudan and the consequent Egyptian evacuation of Harar, the trading post was closed and he went back to Aden. From Harar, however, he had been sent by Bardey on a journey of exploration into Ogaden, the region south of Harar, where no white man had ever penetrated. His report of this journey, in the proceedings of the Société de Géographie (February 1884), aroused some interest.

After the Egyptian withdrawal from Abyssinia, the contest for power between the emperor, John IV, and Menelik, king of Shoa, gave rise to an arms race. Rimbaud, deciding to risk his savings on an expedition to sell arms to Menelik, resigned his position with Bardey (October 1885), and, in October 1886, after a series

of frustrating delays, set out for the interior. He reached the capital of Shoa in February 1887, but unforeseen circumstances and the rapacity and double-dealing of Menelik robbed him of his expected profits, and he returned to Aden no better off than when he had left it, with no prospect of employment, exhausted and embittered. He spent the summer in Cairo, where an account of his journey was published in *Le Bosphore Egyptien* (August 1887), and then returned to Aden, where he sought in vain for work. In May 1888 he returned to Harar, as manager of a trading station for a firm called Tian, which, as well as exporting coffee, gum, ivory, and hides, engaged in the profitable traffic in arms and ammunition. At first Rimbaud's chief business was supplying Menelik with arms but he may also have been in some way associated with the slave trade. However, after John IV was killed (1889) and Menelik became emperor, the profits from gunrunning declined and, although Harar was the chief trading centre of the empire, and the more settled conditions encouraged commerce, Rimbaud lacked the hardheaded business sense needed for success. He lived as simply as the poorest native, spending as little as possible in order to save money so that he could one day retire and live at leisure. His meanness to himself was matched by unobtrusive generosity to others, and the little house where he lived with a native woman became the meeting place of the Europeans in Abyssinia.

His gift for languages and his humane treatment of the Abyssinians made him popular with them, and by his honesty and sincerity he even managed to win the confidence of the chiefs and of Menelik's nephew, the governor of Harar, who became his close friend. He began to wish to do "something good, something useful," and his letters to his mother reveal a longing for affection and intellectual companionship. The marriage of his servant and only close companion, Djami, made him long for a family of his own, and he planned to go home for a holiday and to look for a wife, in the spring of 1891. In February, however, he developed a tumour on his right knee, and when he left Harar, on April 7, he had to be carried by stretcher for the week's journey to the coast. At Aden, the treatment tried had no result and he was sent back to France. He landed at Marseilles in May, and was taken to the Hospital of the Immaculate Conception, where his right leg was amputated. His mother had gone to Marseilles to be with him, but, despite the growing warmth of their letters toward the end of his time at Harar, she remained unable to show her affection for him, to his great disappointment. In letters to his sister, Isabelle, he poured out his sense of frustration and despair, and when, in July, he returned to Roche, a helpless cripple, it was she who looked after him.

He still hoped to marry and return to Abyssinia, but his health grew steadily worse. At last, made wretched by his helplessness and by the gloom of a bad northern summer, in August 1891, he set out on a nightmare journey to Marseilles. His disease was diagnosed as carcinoma, and Isabelle, who had accompanied him, was told that his case was hopeless. He however still believed that he might be cured and endured agonizing treatment. Shortly before he died, Isabelle persuaded him to make his confession to a priest. This conversion seemed to bring him new peace, and to reawaken the poetic imagination of his early youth so that he became once more a *voyant,* seeing visions which, according to his sister, surpassed in depth and beauty those which had inspired *Illuminations.* He died on Nov. 10, 1891, still hoping to return to the East.

Reputation, Poetic Genius, Influence.—While Rimbaud had been in Abyssinia, he had become known as a poet in France. Verlaine had written about him in *Les Poètes maudits* (1884), and had published a selection of his poems. These had been enthusiastically received and, in 1886, unable to discover where he was, or to get an answer from him, he published prose poems under the title *Illuminations,* and further verse poems, in the Symbolist periodical *La Vogue,* as the work of "the late Arthur Rimbaud." It is not known whether Rimbaud ever saw these publications. But he certainly knew of his rising fame after the appearance of *Les Poètes maudits* for, in August 1885, he had received a letter from an old schoolmate, Paul Bourde, who told him of the vogue of his poems—especially "Sonnet des voyelles"—among avant-garde poets. Also he did preserve, for it was among his papers, a letter received in July 1890 from a review inviting him to return to France and put himself at the head of the new literary movement, but he does not seem to have answered it.

Rimbaud was an amazing phenomenon in literature. His meteoric poetic life spanned only five or six years. But in these few years he opened up a rich field for literature, and few poets have been the object of more passionate study, or have exercised greater influence on modern poetry. It is in the prose poem, in *Illuminations,* that he reached the highest peak of his originality, and this is the form best suited to his elliptical and hermetic style, allowing considerable freedom. With him the prose poem was stripped of all the anecdotal, narrative, and even descriptive content of his predecessors, and it is highly concentrated. In these poems he increased the evocative power of literature, independently of the sense conveyed, and words with him are no longer meant to bear their dictionary meaning or to express logical content, but are a form of magic charm, and are intended to evoke a state of mind—*"état d'âme,"* the Symbolists were to say. He also showed how much rich material exists for poetry in the subconscious mind, and in the half-remembered sensations of childhood. Finally, after nearly a century, his writings are still capable of expressing intensely modern revolt and recoil from the very essence of life in a so-called civilized society.

BIBLIOGRAPHY.—*Editions and Correspondence:* The first collected edition of Rimbaud's writings was that by P. Berrichon and E. Delahaye (1898); the only complete edition, including correspondence, rough notes, etc., is the Édition de la Pléiade by J. Mouquet and R. de Renéville (1946). The best annotated edition is that for the Classiques Garnier by S. Bernard (1960). His correspondence from the East was edited by P. Berrichon, in *Lettres de Jean-Arthur Rimbaud (Égypte, Arabie, Éthiopie)* (1899). Earlier letters were edited by J. M. Carré as *Lettres de la vie littéraire* (1931).

Biography and Criticism: The first complete biography was P. Berrichon, *La Vie de Jean-Arthur Rimbaud* (1897). Of many other works the most notable are: P. Verlaine, *Les Poètes maudits* (1884); M. Coulon, *Le Problème de Rimbaud* (1923); E. Delahaye, *Rimbaud l'Artiste et l'Être Moral* (1923); E. Rickword, *Rimbaud, the Boy and the Poet* (1924); R. de Renéville, *Rimbaud le voyant,* 3rd version (1947); F. Ruchon, *Jean-Arthur Rimbaud* (1929); B. Fondane, *Rimbaud le voyou* (1933); R. Étiemble and Y. Gauclère, *Rimbaud* (1936); C. Hackett, *Rimbaud l'enfant* (1948); H. de Bouillane de Lacoste, *Rimbaud et le problème des Illuminations* (1949); J. Gengoux, *La Pensée poétique de Rimbaud* (1950); R. Étiemble, *Le Mythe de Rimbaud* (1952–54); E. Noulet, *Le Premier Visage de Rimbaud* (1953); D. de Graaf, *Arthur Rimbaud* (1961); E. Starkie, *Rimbaud en Abyssinie* (1938), *Arthur Rimbaud,* 3rd version (1961); H. Matarasso and P. Petitfils, *Vie d'Arthur Rimbaud* (1962). (E. St.)

RIME, a beautiful, white, friable, crystalline ice deposit formed by freezing of supercooled cloud- or fog-water droplets on objects exposed to the air. It occurs in two typical shapes: (1) growths of uniformly short, projecting, feathery branching crystal aggregates on all sides of a freely exposed object; and (2) asymmetrical growths of crystal aggregates in the form of long plumes or flags orientated into the direction held by the wind during the formation of the deposit. The latter type, which may reach a length of six feet, is common on exposed upper slopes of mountains in middle and high latitudes; the terms "frozen fog deposit" and "frost feathers" are often applied to the phenomenon in such places. The first type is less common and occurs chiefly in valleys from winter ground fogs with calm air. Under the microscope, rime appears to be a mosaic agglomeration of minute crystal accretions, almost amorphous, with spaces of entrapped air. Often wind-blown snowflakes become embedded in the deposit, giving it a greasy consistency when crushed between the fingers. When the temperature at formation is just below freezing, the rime becomes a denser, smoother deposit which is hard and tenacious like ordinary ice, sometimes called rough frost, or hard rime, in contradistinction to the more usual types, or soft rime. Some hydrologists and glaciologists claim that the larger part of the alimentation of the icecaps in such regions as Greenland, Norway, Iceland, and Spitsbergen is provided by rime depositing on the surfaces of the mountain snowfields. Field measurements, however, cast some doubt on the general validity of this assumption. *See* also FROST. (R. G. Se.)

RIME (RHYME) **ROYAL,** the name given to a stanza form of seven decasyllabic (iambic) lines, rhyming *a b a b b c c*. The name is traditionally derived from use of the form in *The Kingis Quair,* attributed to James I of Scotland (1394–1437). Introduced to England by Chaucer (*c.* 1340–1400) in *Troilus and Criseyde* and *The Parliament of Fowls,* it became the favourite form for long narrative poems during the 15th and early 16th centuries.

Chaucer probably borrowed it from the French poet and musician Guillaume de Machaut (*c.* 1300–77), who may have invented it or derived it from earlier French and Provençal poets. Chaucer's skilful use of it recommended it to his followers in England and Scotland (*see* ENGLISH LITERATURE: *From Chaucer to the Renaissance: Poetry: The Chaucerian Tradition;* SCOTTISH LITERATURE: *The Makaris*). It continued to be popular in the 16th century, and, after Chaucer, one of the most successful writers of rime royal was Thomas Sackville, who used it for his *Induction* to the 1563 edition of *A Mirror for Magistrates.* Shakespeare's *Lucrece* (1594) is, perhaps, the last important poem of the period in rime royal, although Milton experimented with it, and it was used by Sir Francis Kynaston (1587–1642)—an admirer of Chaucer who translated part of *Troilus and Criseyde* into Latin rime royal—for *Leoline and Sydanis* (1642). By this time, however, it had been generally replaced by the octave. It was successfully revived by William Morris (1834–96).

RIMINI (anc. ARIMINUM), a town of Forlì province, Italy, and the seat of a bishopric, lies on the Riviera del Sole of the northern Adriatic Coast, a short distance from the foot of the Apennines where the steep Monte Titano is crowned by the republic of San Marino. Pop. (1961) 94,403 (commune). Area of commune 59 sq.mi. (152 sq.km.).

The plan of the old Roman city is apparent in the area between the Marecchia river, the Ausa torrent and the railway, where streets follow the ancient lines. The crumbling remains of 15th-century walls raised under the rule of the Malatesta family, when the town was extended, stretch along the left bank of the Marecchia. The town was divided into four quarters, known since the 18th century as Cittadella, Clodio, Pataso and Montecavallo. In the mid-19th century the suburbs of S. Giuliano, Mazzini and Marina grew up outside the walls and the first bathing stations on the coast were joined to the town by Principe Amedeo avenue. Since 1920 the town expanded farther south and the seaside suburbs of Marebello, Riva Azzurra and Miramare came into being, and many fashionable houses and hotels were built. In spite of the destruction of 90% of its houses during World War II the town recovered, and its seaside resorts stretch for nearly 10 mi. from Torre Pedrera to Miramare. The centre of the town is the Piazza Giulio Cesare, the meeting point of the old Roman roads Via Flaminia and Via Aemilia; nearby are most of the monuments.

Monuments.—The oldest monument is the arch of Augustus, erected in 27 B.C. over the south gate of the city, but not finished until A.D. 22, by Tiberius; it was dedicated to Augustus. It has a single opening and a frieze added in the middle ages. The bridge built by Augustus over the Marecchia and also completed by Tiberius (A.D. 21) had a fifth arch added in 552. There are some remains of a Roman amphitheatre. Only ruins remain of the castle built by Sigismondo Pandolfo Malatesta (see *History,* below) in 1446. Rimini's most famous building is the Malatesta temple, designed to glorify Sigismondo's love for the beautiful Isotta degli Atti. Converted from the old Gothic church of S. Francesco, the temple was designed by Leon Battista Alberti, and the decoration of the interior was mostly the work of Agostino di Duccio, who enriched it with exquisite reliefs: figures of the liberal arts, the sybils, angels with fluttering veils, shields with the Malatesta arms, the planets and the moon, dancing children holding festoons of flowers and fruit; everywhere are repeated the intertwined initials S and I. The scheme for the temple, a monument of frankly pagan character, remained unfinished on Sigismondo's death.

Churches include S. Giovanni Evangelista (1247), with painted murals of the 13th-century Romagna school; S. Giuliano (16th century), built on the site of a Benedictine abbey, which preserves an altarpiece by Paolo Veronese; the little octagonal temple of S. Antonio on the Piazza Giulio Cesare; and the church of the Servi (14th century, rebuilt in the 16th). Other buildings include the restored Palazzo dell'Arengo (1202). The Piazza Cavour has a 15th-century fountain of Giovanni da Carrara. A bronze statue of Paolo V, begun by Niccolo Cordier and finished by Sebastiani di Recanati, was later transformed into S. Gaudenzio, patron saint of the town. The picture gallery contains Dutch arras of the 16th and 17th centuries and pictures by Giovanni Bellini, Ghirlandaio and Giuliano da Rimini. The Gambalunghiana civic library (1619), badly damaged in World War II, was afterward repaired, and preserves valuable incunabula and illuminated manuscripts.

Communications and Commerce.—Rimini is an important railway junction of the lines to Brindisi in the south, Venice and Trieste in the north and Bologna and Turin in the west, and is also a road centre. It has sea links with Ancona, Ravenna, Venice and Trieste, and an airport at Miramare. The district is rich in cereals and fruit and the town is equipped with processing factories and railway repair shops. The principal occupation, however, is the tourist industry. The gently sloping beaches backed by promenades and hotels are an attractive feature, and international shows, sporting events, concerts, etc., take place.

History.—The Roman city, called Ariminum from the old name of the Marecchia, Ariminus, stood on the boundary of Aemilia and Umbria. According to Strabo it belonged to the Umbro-Etruscan civilization. It was occupied in 268 B.C. by the Romans, and a Latin colony founded there. During the Second Punic War it was a base for military and naval operations. It became a Roman municipality and was later sacked by Sulla's troops. It witnessed the decisive step taken by Julius Caesar, when he crossed the Rubicon and marched on Rome.

In A.D. 359 the town was host to the Council of Rimini, which failed to resolve the Arian dispute. Rimini passed to the Byzantines and from them to the Goths, from whom it was recaptured by Narses, and then fell to the Lombards and Franks. It was for a long time governed for the pope by dukes and counts till the end of the 10th century when the imperial power became dominant. Transformed in the 13th century into an independent commune, it was the scene of struggles between the Guelphs and Ghibellines (*q.v.*). The leaders of the Guelphs were the Malatesta family who had established themselves at Verucchio and Rimini.

In 1239 Malatesta da Verucchio was made *podestà* ("mayor") of Rimini. The struggle with the Ghibellines had a respite when his son Malatesta II married Concordia Pandolfini, daughter of the Ghibelline leader, but her death broke the truce. Malatesta II's long life was filled with struggles and misfortunes, among them the tragedy when his son Gianciotto the Lame killed his own wife, Francesca da Polenta, daughter of the lord of Ravenna, and his brother Paolo the Fair, her secret lover. This episode was immortalized by Dante (*Inferno,* v, 73 ff.) and in Silvio Pellico's tragedy *Francesca da Rimini.* In 1334 the Council of Rimini recognized the family as lords of the town and for two centuries the town's history was united with that of this family.

Sigismondo Pandolfo Malatesta (1417–68), lord of Rimini, Fano and Senigallia, was the personage to whom Rimini principally owes its renown during the Renaissance. An unscrupulous tyrant but a valiant soldier who understood the science of fortification, he was a man of letters and a patron of the arts. Both his first wife, Ginevra d'Este, daughter of Lionello, duke of Ferrara, and his second, Polissena, daughter of Francesco Sforza, later duke of Milan, died, and Sigismondo was accused of having killed them in order to marry Isotta degli Atti.

The quarrels and rivalries of Sigismondo with other rulers and the papacy led to Pope Pius II's indictment of him in 1461. Sigismondo was compelled to submit and yielded most of his territory to the pope, keeping only Rimini and a few lands. After commanding an expedition for the Venetians against the Turks in the Morea he returned to Rimini in the hope of recovering his dominions from the new pope, Paul II. Unsuccessful in this, he went to Rome with the intention of stabbing the pope; when

Paul received him in the presence of his cardinals, Sigismondo lost courage and returned to Rimini where he died on Oct. 3, 1468, appointing his wife Isotta and their son Sallustio to succeed him.

Sigismondo's illegitimate son, Roberto, had assisted him in his struggle against Pius II, and on his father's death got rid of the legitimate heirs and made himself lord of Rimini. Reconciled with the pope, Roberto became commander in chief of the papal army. His son Sigismondo failed to defend his lands against Cesare Borgia.

Following the league of Cambrai in 1508, Rimini and its lands passed to the papal states. In 1815 it was occupied by Joachim Murat, king of Naples and brother-in-law of Napoleon, whose "Rimini proclamation," promising the Italians a constitution, failed in its purpose when Murat was defeated by the Austrians at Tolentino. Rimini then returned to the papal states. The Rimini manifesto which accompanied the insurrection of Sept. 23, 1845, reflected the ideas of the moderate party and asked for political reforms in the modern sense. In 1860 Rimini was annexed to the kingdom of Italy. During World War II it suffered severe bombardment for it lay on the easiest route to the Po plains.

(M. T. A. N.)

RIMSKI-KORSAKOV, NIKOLAI ANDREEVICH (1844–1908), one of the principal nationalist figures in Russian music of his time, was born at Tikhvin, in the Novgorod *guberniya,* on March 18 (new style; 6, old style), 1844. In 1861, when he was a student at the St. Petersburg naval school, he made the acquaintance of M. A. Balakirev (*q.v.*) and his circle, and was inspired to study music and to compose. His First Symphony was partly written during a three-year cruise in foreign waters (1862–65) and was successfully performed in St. Petersburg on his return. In 1871 he was appointed professor of composition and instrumentation at the St. Petersburg Conservatory, though he did not leave the navy till 1873; in that year his first opera, *The Maid of Pskov,* was produced in St. Petersburg. Two further operas, *May Night* (1880) and *Snow Maiden* (1882), were produced in St. Petersburg, and in 1887 and 1888 he wrote three brilliant orchestral works, the *Spanish Capriccio, Sheherazade,* and the *Russian Easter Festival Overture.* About this time he occupied a number of official positions: inspector of naval bands (1873–84), director of the Free School of Music concerts (1874–81), assistant music director of the Imperial Chapel (1883–94), conductor of the Russian Symphony Concerts (1886–1900). His pupils at the conservatory at this period included some of the outstanding composers of the following generation, notably Liadov and Glazunov. He also found time to complete, orchestrate or re-orchestrate, and drastically edit the unfinished works of his friends Borodin and Mussorgsky. Without his editorial work neither the *Prince Igor* of the one nor the *Khovanshchina* of the other could ever have been staged; but his total rewriting of the completed *Boris Godunov,* however well-intentioned and brilliant in result, was misguided (*see* also MUSSORGSKY, MODEST PETROVICH).

THE BETTMANN ARCHIVE INC.

NIKOLAI RIMSKI-KORSAKOV, PHOTOGRAPHED IN 1904

Between 1891 and 1893 Rimski-Korsakov passed through a physical and intellectual crisis marked by an inability to compose and even a distaste for music itself. Recovering, he composed the opera *Christmas Eve* (St. Petersburg, 1895), and followed it with a series of operas produced in Moscow, including *Sadko* (1898), *The Tsar's Bride* (1899), *The Story of Tsar Saltan* (1900), and *Kashchei the Immortal* (1902). *Kitezh* was produced in St. Petersburg in 1907 and *The Golden Cockerel* was produced posthumously in Moscow in 1909. This series of operas contains much of his finest music.

In the course of the revolutionary disturbances of 1905, Rimski-Korsakov defended the rights of the conservatory students against the reactionary director; he was in consequence dismissed and became a hero of the liberals. Demonstrations after a performance of *Kashchei* led to the imposition of a two-month ban on the performance of all his works, with the result that they became unprecedentedly popular when it was lifted. Rimski-Korsakov was later reinstated at the conservatory but took advantage of the period of retirement to complete his memoirs, *Letopis moei muzykalnoi zhizni* (new edition, 1955; English translation by J. A. Joffe, *My Musical Life,* 1942), a book of great interest and importance. In May 1907 he visited Paris to take part in Diaghilev's festival of Russian orchestral music. He had not quite completed another important book, *Principles of Orchestration* (edited by M. Steinberg; English translation by E. Agate, 1923), when he died at Lyubensk, near St. Petersburg, on June 21 (N.S.; 8, O.S.), 1908.

Rimski-Korsakov was one of the greatest masters of orchestration in the history of music. His handling of the orchestra influenced not only his pupils Stravinsky and Respighi but Debussy, Ravel and other French musicians, Gustav Holst, and many others. He was a melodist but he lacked the dramatic power and architectural sense necessary to a symphonist. His unique contribution was the half-real, half-fantastic world portrayed in the best of his operas.

RINDERPEST, a disease of ruminant animals, primarily cattle, has been known also as steppe murrain, contagious bovine typhus, and cattle plague. Rinderpest was first recognized in early Christian times. Earliest records suggest that it originated in Asia or Eastern Europe, its incursions into Western Europe having followed the paths of invading armies in the periodic sweeps of barbarous tribes from the east. Rinderpest killed cattle by the thousands in Europe in the 18th and 19th centuries. The disease reached Africa in the late 19th century and, after spreading throughout the continent with disastrous effect, was eventually cleared from the southern half but remained endemic in the northern parts, its southernmost extension being in Tanganyika (Tanzania). The disease is also endemic in India and parts of southeastern Asia. It has occurred, but was quickly eradicated, in Brazil and Australia. Rinderpest has not been reported in the United States.

Characteristics.—Rinderpest is an acute, highly contagious disease characterized by an unusually rapid course and high mortality, especially in areas where it is not endemic. The causative agent is the virus *Tortor bovis.*

Signs of illness appear after an incubation period of three to five days. Early signs are depression and loss of appetite accompanied by fever, generally of 105° to 107° F (about 40° C). In the midcourse of the disease, ocular and nasal discharges and salivation with buccal ulceration and a disagreeable fetid odour are characteristic. Profuse diarrhea with progressive emaciation and dehydration occur, often with dysentery, and eventually marked straining to evacuate. In many cases an eruptive condition termed streptothricosis develops on the back and flanks. Prostration, coma, and death come usually after four to eight days.

Autopsy shows involvement of the mucous membrane of the entire alimentary tract. This is usually most marked in the mouth, where ulcers containing cheesy deposits are often found, and in the abomasum (fourth stomach), intestines, and rectum, where deep congestion and sometimes ulceration occur. In the lower bowel the congestion is often in well-defined, dark streaks referred to as zebra marking. Pneumonia frequently is seen as a complication, and often cystitis and vaginitis are present. Diagnosis is made on the clinical appearance of the disease and autopsy findings, but, since these may be similar to those found in certain other

diseases, virus transmission and cross-immunity tests are necessary for confirmation.

Spread and Control of the Disease.—The virus is generalized in the animal body and is passed out in all the secretions. It gains access to the tissues of a susceptible animal via the mucous membranes, most probably those of the nostrils. In areas where the disease is endemic, wild animals play an important part in the epidemiology. Many species of wild ruminants, together with wild pigs and warthogs in such areas as Tanganyika and Uganda, are susceptible to rinderpest and form vast reservoirs of infection. These animals come into contact with domestic animals in competition for limited grazing and water. Eradication of rinderpest in these areas depends therefore on control of the disease in wild animals or elimination of their contact with domestic animals. In nonendemic areas, strict quarantine measures alone can be effective. However, it was early recognized that some form of immunization combined with quarantine was the most promising method of control under all circumstances. By mid-20th century a number of effective vaccines had been developed.

(J. A. Br.; J. K. H. W.; X.)

RINEHART, MARY ROBERTS (1876–1958), U.S. novelist and playwright best known for her mystery stories beginning with *The Man in Lower Ten* (serialized 1907) and *The Circular Staircase* (1908), her first book. Born in 1876 in Pittsburgh, Pa., she received nurse's training there and in 1896 married Stanley M. Rinehart, a physician. In 1903 the family found itself in financial difficulties as a result of a stock market crash, and Mrs. Rinehart turned to writing; her work proved to be a great popular success almost from the beginning. A long series of comic tales about the robust, redoubtable "Tish" (Miss Letitia Carberry) appeared in the *Saturday Evening Post* through many years. Of her plays (most of them written in collaboration with Avery Hopwood), the most successful was *The Bat* (1920), derived with significant changes from *The Circular Staircase*. She produced as well, always with a keen responsibility to her craft, a number of romances and several books of travel, some of the latter reflecting her experience as a correspondent during World War I. She died in New York City on Sept. 22, 1958.

Mrs. Rinehart established what has been called the "had-I-but-known" sort of mystery, and her tales make it plain that she was mistress of a form in which few other writers excelled.

RING: *see* Jewelry.

RINGKÖBING (Ringkøbing), the largest Danish *amt* (county), covers a rectangular area bounded by the smooth dune and lagoon coast of western Jutland between Nissum Bredning and the southern shore of Ringköbing Fjord, and extending about 40 mi. (64 km.) inland across old morainic landscape and sandy outwash plains (*see* also Denmark: *Physical Geography*). Area 1,799 sq.mi. (4,659 sq.km.). Pop. (1960) 205,772. It is a district of rather poor mixed farming with tracts of unreclaimed heath. The principal towns, Herning (pop. [1960] 24,790) and Holstebro (18,563), lie inland. Struer, Lemvig, and Ringköbing are minor ports.

(Ha. T.)

RING TENNIS: *see* Deck Tennis.

RINGWORM: *see* Skin, Diseases of.

RIOBAMBA, a city in highland Ecuador, capital of the province of Chimborazo. Pop. (1962) 61,509. It is located at an elevation of about 9,000 ft. in the basin of Riobamba, just south of Mt. Chimborazo and about 100 mi. S of Quito. It is reached by railroad or by the Pan-American Highway from both Quito and Guayaquil. Domestic airlines serve its airport. The railroad and highway pass a short distance to the west of the city, and connection is by branch line and an all-weather road. A weekly fair held in the central plaza attracts Indian farmers from the surrounding countryside. Small-scale manufacturing industries produce cotton and woolen textiles, carpets, shoes, beer, liquor, butter, and cheese. The first constitution of Ecuador was proclaimed there in 1830.

(P. E. J.)

RÍO CUARTO, a town of Argentina in the province of Córdoba, 140 mi. S of the city of that name, and about 385 mi. NW of Buenos Aires. Pop. (1960) 70,505. It stands 1,440 ft. above sea level and about halfway across the great Argentine pampas, on the banks of a river of the same name. The town is built on the open plain and is surrounded with attractive suburbs. It is the commercial centre of a big district and has a large and lucrative trade. Its geographical position gives it great strategic importance, and the government maintains there a large arsenal and a garrison of the regular army. Before 1872 this region was overrun by the Ranqueles, a warlike tribe of Indians. The surrounding country belongs to the partially arid pampas region and is devoted to stock-raising agriculture. Irrigation is employed in its immediate vicinity. There are some manufacturing industries in the town, although it is primarily an agricultural centre. The San Martín and the Mitre railways pass through Río Cuarto, giving railway communication with Buenos Aires, Rosario, Tucumán, Córdoba, San Luis, Mendoza, and other cities.

The revolution which overthrew President Perón in 1955 began with an uprising at the Río Cuarto military air base.

(Ge. P.)

RIO DE JANEIRO, one of Brazil's maritime states, is bounded by the Atlantic Ocean and the states of Espírito Santo, Minas Gerais, and São Paulo. Brazil's former federal district containing the city of Rio de Janeiro and fronting on the Guanabara bay forms a small enclave near the middle of the state. Area 16,568 sq.mi., pop. (1960) 3,402,728.

Historically it is closely associated with the city Rio de Janeiro. Its territory was selected by the Portuguese for some of their first settlements, and on parts of its coast the French waged their early struggles for the control of Brazil's resources. When Brazil was divided into captaincies in 1642, Rio de Janeiro was one of the original ten. The city of Rio de Janeiro was the seat of the captaincy's government and centre of its social and economic life throughout the colonial period. After independence was declared the *município* or county containing the national capital was separated from the state and made into a federal district.

The territory of the state may be divided roughly into four regions, namely: a low, narrow, and irregular coastal plain; the Baixada Fluminense, a large basin surrounding Guanabara Bay; the rugged chain of mountains, Serra do Mar, which traverses the state longitudinally; and the large valley through which the Paraíba River flows northeastward to the Atlantic. In the northeastern part of the state this river cuts through the mountain chain and its valley then broadens out into a rich alluvial plain on which for centuries sugar plantations were the basis for the wealth of some of Brazil's most opulent families. The climate is tropical or subtropical depending on altitude.

Agriculture long was the mainstay of the state's economy, but since World War II industrialization has proceeded rapidly. The chief crops are coffee, oranges, bananas, sugarcane, rice, and corn, but many other fruits and truck crops are grown. The cattle population numbers more than 2,000,000; and the salt refineries and fisheries are among the most important in Brazil. Since 1945 the industrial belt surrounding the city of Rio de Janeiro and the iron and steel centre at Volta Redonda in the upper Paraíba Valley developed tremendously. Pig iron, steel, steel products, textiles, cement, and food products are the principal industrial products. Rio de Janeiro is a leading state in hydroelectric power production.

The major cities are: Niterói (*q.v.*), the state capital, on Guanabara Bay opposite the city of Rio de Janeiro (*q.v.*); Campos; Petrópolis (*q.v.*), the nation's summer capital; Duque de Caxias, Nova Iguaçu, São João de Meriti, and Nilópolis, all suburbs of Rio de Janeiro.

The state is served by road and rail networks which radiate from the great port of Rio de Janeiro. Most of the 1,663 mi. of railroads in service belongs to two systems, the Central do Brasil whose main lines connect the city of Rio de Janeiro with São Paulo and with Belo Horizonte, and the Leopoldina Railway which links Rio de Janeiro and Niterói with places to the north and east.

(T. L. Sh.)

RIO DE JANEIRO (in full, São Sebastião do Rio de Janeiro, colloquially shortened to Rio), a city and port of Brazil, capital of the republic until 1960, when Brasília (*q.v.*) became the capital, on the western side of Rio de Janeiro, or Guanabara bay. The city occupies about 60 sq.mi. in the southeast angle of Guana-

bara state, formerly the Federal District, which was until 1960 an independent commune with an area of 524 sq.mi., detached from the province of Rio de Janeiro in 1834. The city stands in great part on an alluvial plain formed by the filling in of the western shore of the bay, which extends inland from the shore line in a northwesterly direction between a detached group of mountains on the south known as the Serra da Carioca, and the imposing wooded heights of the Serra do Mar on the north. The spurs of the Carioca range project into this plain, in some places close up to the margin of the bay, forming picturesque valleys within the limits of the city. Some of the residential quarters follow these valleys up into the mountains and extend up their slopes and over the lower spurs, which, with the hills covered with buildings rising in the midst of the city, give the city a distinctive charm. At the entrance to the bay is Sugar Loaf mountain (Pão de Acúcar), a conical rock rising 1,296 ft. above the water level and forming the terminal point of a short range between the city and the Atlantic coast. The culminating point of that part of the Carioca range which projects into and partly divides the city is the Corcovado (Hunchback), a sharp rocky peak, 2,310 ft. above the Botafogo inlet, on whose narrow summit towers the imposing statue 98½ ft. high of Christ the Redeemer, the construction of which was completed in 1931. The Corcovado, approachable either by road or inclined railway, provides a point of vantage from which the entire capital, the bay and its surrounding districts may be viewed. Considerably beyond the limits of the city on its southwest side is the huge isolated flat-topped rock known as the Gávea, 2,736 ft. high, which received its name from its resemblance to the square sail used on certain Portuguese craft. The sky line of this range of mountains, as seen by the approaching traveler several miles outside the entrance to the bay, forms the rough outline of a reclining figure called "the sleeping giant."

The entrance to the bay, between the Sugar Loaf on the west and the Pico do Papagaio (Parrot's Beak) on the east, with the fortress of Santa Cruz on one side and the fort of São João on the other, is about a mile wide. Although the entrance is free from obstructions, dangerous swells are produced by a deeply submerged bar whenever storms come out of the south or southwest. Almost midway in the channel is the little island and fort of Laje, temporary site of the first Huguenot settlement in Rio de Janeiro. On the west is the semicircular bay of Botafogo, round which are grouped the residences of one of the wealthiest suburbs; on the east, the almost landlocked bay of Jurujuba. (*See* NITERÓI.)

The bay extends northward about 16 mi. from the entrance channel, opening to a maximum width of about 15 mi. near its head. The irregular shore line was modified by the construction of sea walls and the filling in of shallow bays. Close to the shore are the islands of Villegaignon (occupied by the national naval academy), Cobras (occupied by fortifications, naval storehouses, hospital and dry docks), Santa Bárbara and Enxadas.

The oldest part of the city, which includes the commercial section, lies just south of São Bento, Conceicão and Livramento hills, and extends inland to the Praça da República, though the defensive works in colonial times followed a line much nearer the bay. This section was extended southward along the bay shore during the 19th century and led to the development of a string of suburbs such as Catete and Botafogo, with that of Laranjeiras behind Catete in a pretty valley of the same name, Leme, Copacabana, Ipanema, Leblon and Gávea. Rio's famous botanical garden, which dates from the 19th century, is also located in this area on the western shore of Lagôa Rodrigo de Freitas. The major trend of later development was northward and westward, where are to be found the suburbs of São Cristóvão, Engenho Novo, Vila Isabel, Tijuca, Andaraí, Rio Comprido, Cajú and others, some of which are residential, while others are essentially industrial. The outlying, poorer suburbs are reached by the Central do Brasil railway; those closer in are served by street railways and buses. The population of the former Federal District, according to the census of 1960, was 3,307,163; and of the city 3,223,408. Rio's citizens are known locally as *cariocas*.

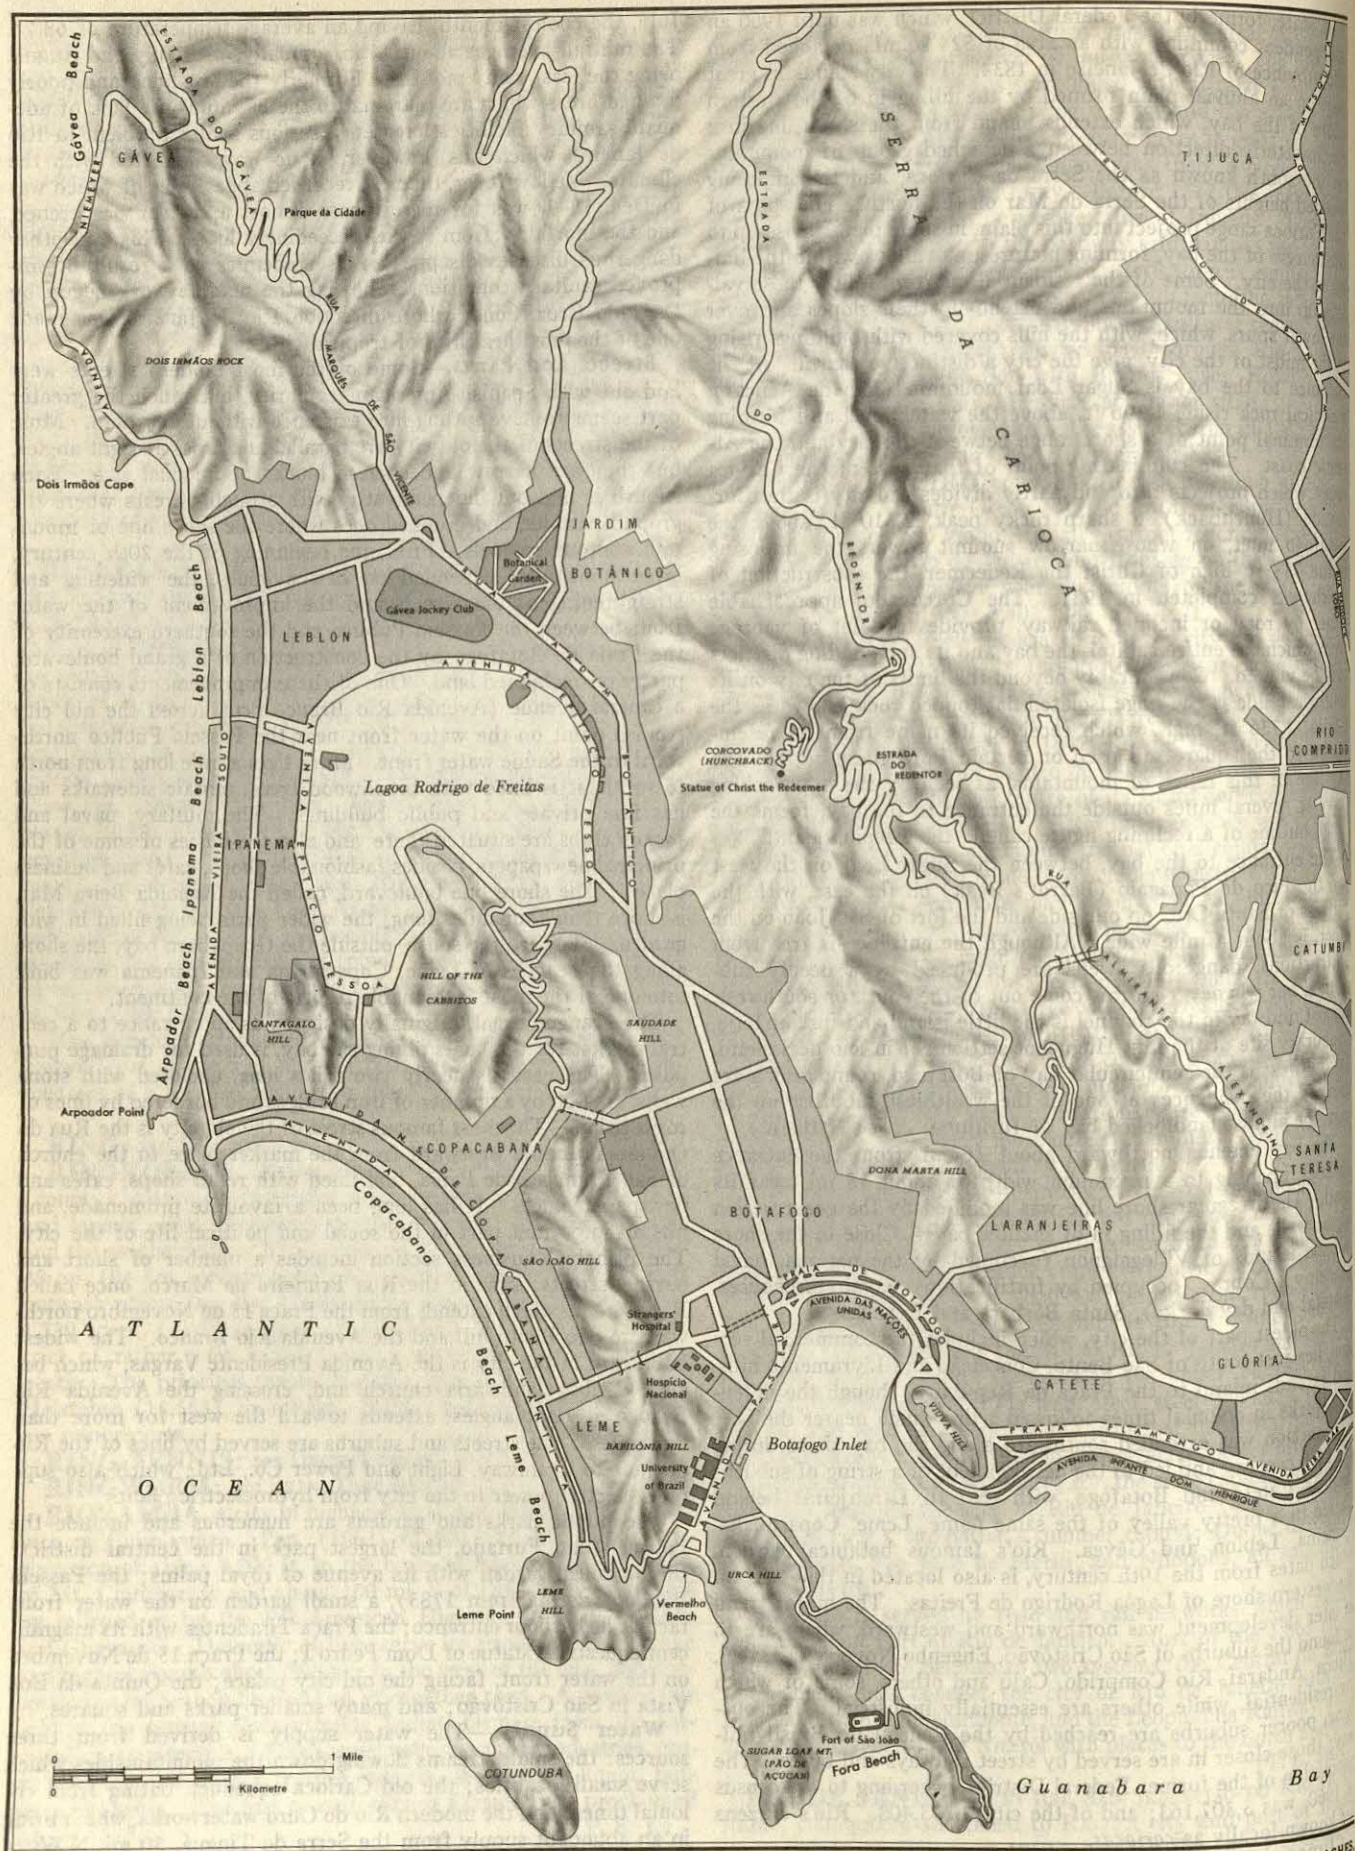
Climate.—The climate of Rio de Janeiro is warm and humid, the average temperature for the year being about 74° F., with July, the coolest month, having an average temperature of 68.7°. The rainfall averages about 44 in. annually, with July and August being the least rainy months. Formerly the low-lying and poorly drained areas which are marginal to the bay, plus the lack of adequate sanitary facilities, created a serious health problem in Rio de Janeiro, which was, however, in no way connected with the climate. Yellow fever, the first recorded appearance of which was in Dec. 1849, was for many years almost a regular occurrence, and the mortality from it was exceedingly high. This and other dangerous diseases disappeared as epidemics as a result of improved sanitary conditions following the notable work begun by Oswaldo Cruz, under whose direction Rio de Janeiro was made one of the most healthful of tropical cities.

Streets and Parks.—Some of the most modern streets were laid out with Spanish-American regularity, but much the greater part seems to have sprung into existence without any plan. Most of the streets of the old city are parallel and cross at right angles, but they are narrow and enclose blocks of unequal size. Each suburb is laid out independently, with straight streets where the ground permits, and crooked ones where the shore line or mountain contour compels. From the beginning of the 20th century, large sums were expended on new avenues, the widening and straightening of old streets and the improvement of the water front between the Passeio Público and the southern extremity of the Praia de Botafogo by the construction of a grand boulevard, partly on reclaimed land. One of these improvements consists of a central avenue (Avenida Rio Branco) cut across the old city from a point on the water front near the Passeio Público northward to the Saúde water front. More than a mile long from north to south, it is lined with brazilwood trees, mosaic sidewalks and has fine private and public buildings. The military, naval and jockey clubs are situated there, and also the offices of some of the principal newspapers, besides fashionable shops, cafés and business places. The shore line boulevard, called the Avenida Beira Mar, is more than four miles long, the wider parts being filled in with gardens. Toward the south, outside the Guanabara bay, the shore along the beaches of Leme, Copacabana and Ipanema was built into one of the most fashionable resorts of the continent.

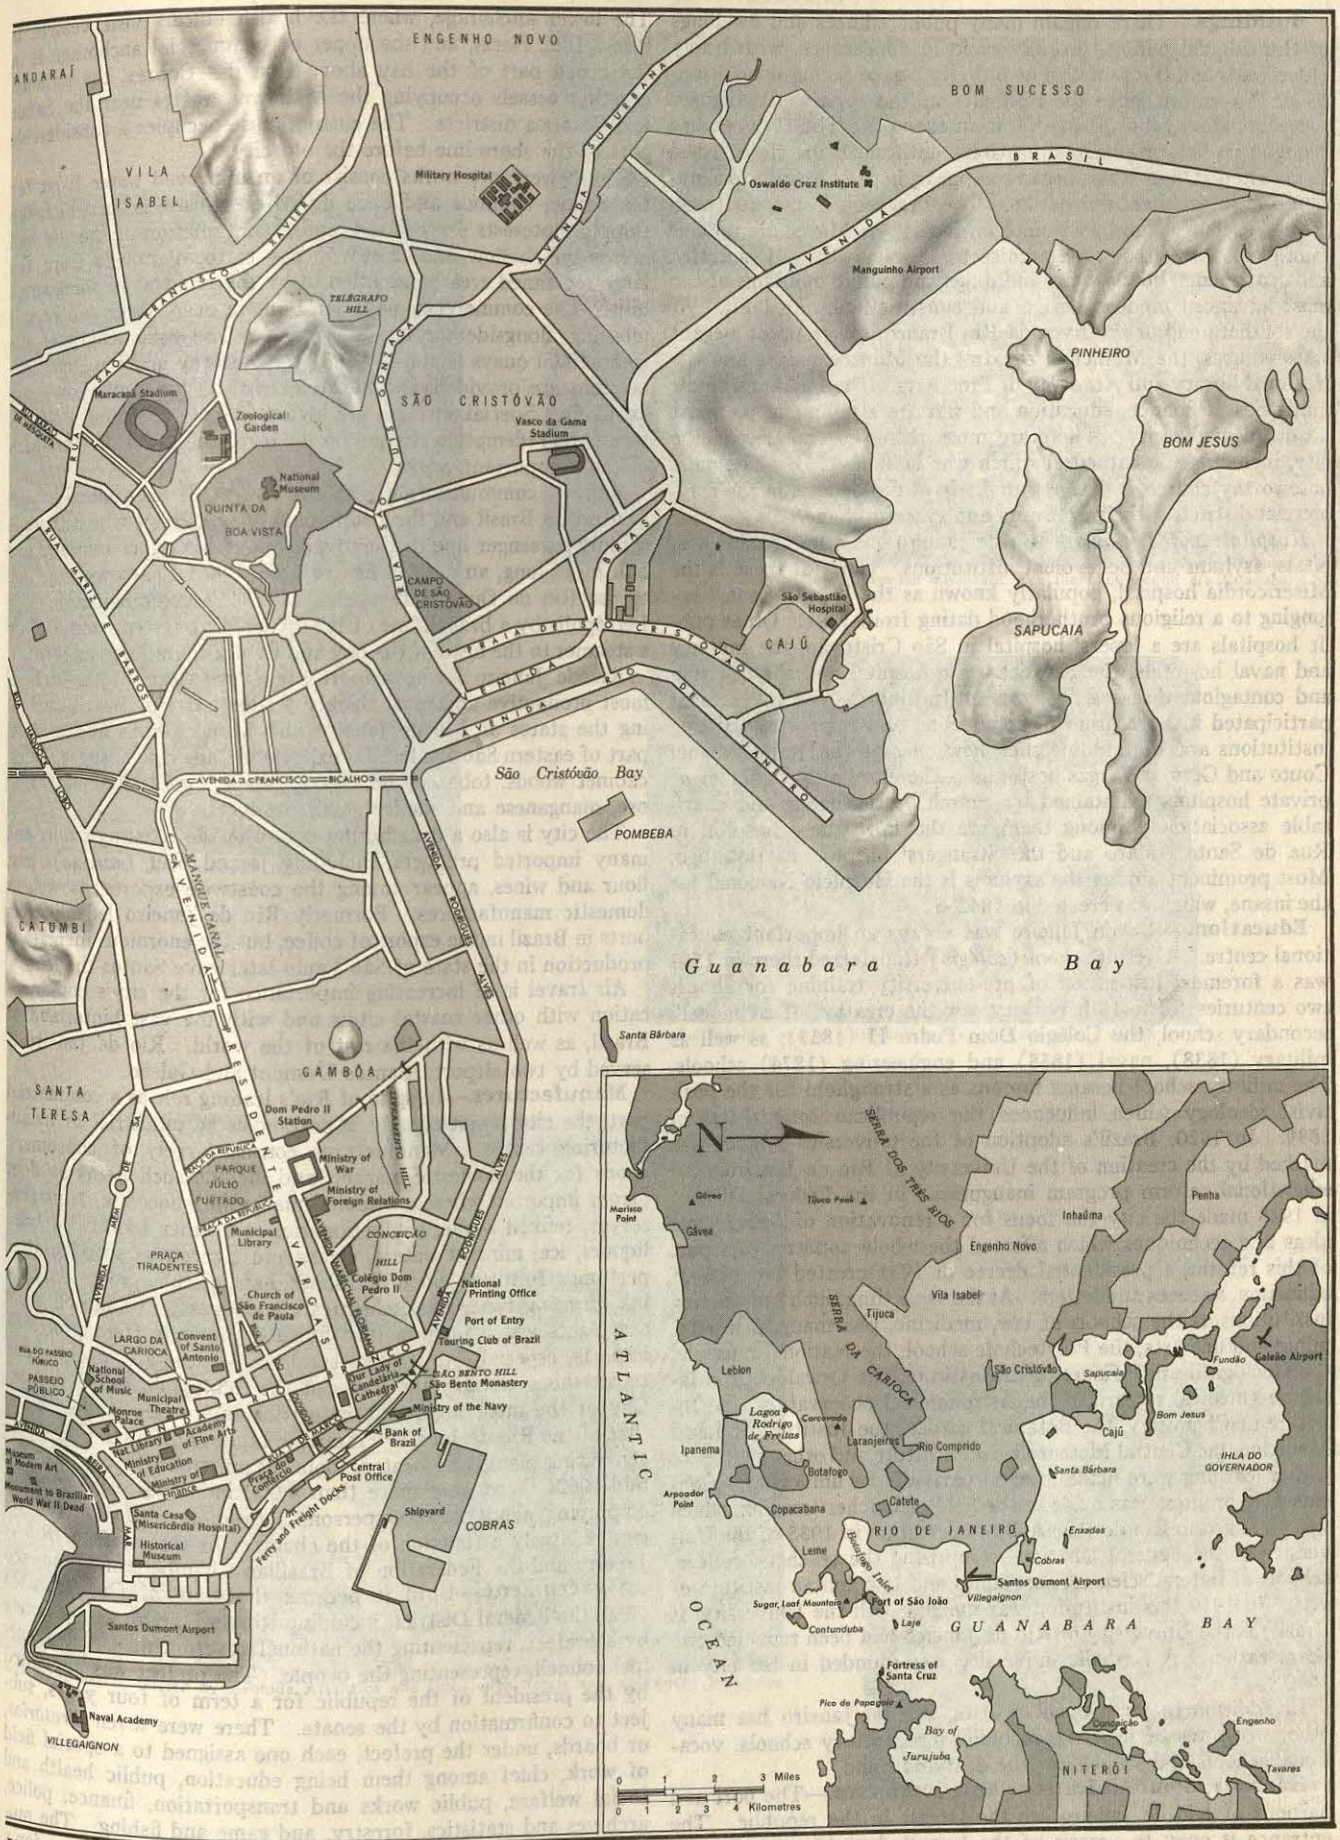
The Mangue canal, originally designed as an entrance to a central market for the boats plying the bay, is used for drainage purposes. The canal is nearly two miles long, enclosed with stone walls, crossed by a number of iron bridges and bordered by lines of royal palms. The most famous street of the old city is the Rua do Ouvidor, running westward from the market place to the church of São Francisco de Paula, and lined with retail shops, cafés and newspaper offices. It has long been a favourite promenade, and fills an important part in the social and political life of the city. The principal business section includes a number of short and narrow streets between the Rua Primeiro de Marco, once called Rua Direita, which extends from the Praça 15 de Novembro northward to São Bento hill and the Avenida Rio Branco. The widest boulevard in the city is the Avenida Presidente Vargas, which begins at the Candelária church and, crossing the Avenida Rio Branco at right angles, extends toward the west for more than two miles. The streets and suburbs are served by lines of the Rio de Janeiro Tramway, Light and Power Co., Ltd., which also supplies electric power to the city from hydroelectric plants.

The public parks and gardens are numerous and include the Parque Júlio Furtado, the largest park in the central district; the botanical garden with its avenue of royal palms; the Passeio Público (dating from 1783), a small garden on the water front facing the harbour entrance; the Praça Tiradentes with its magnificent equestrian statue of Dom Pedro I; the Praça 15 de Novembro on the water front, facing the old city palace; the Quinta da Boa Vista in São Cristóvão; and many smaller parks and squares.

Water Supply.—The water supply is derived from three sources: the small streams flowing down the mountainsides which serve small localities; the old Carioca aqueduct, dating from colonial times; and the modern Rio do Ouro waterworks, which bring in an abundant supply from the Serra do Tinguá, 30 mi. N.W. of the city. An extensive system of sewers was constructed and a separate system of rain-water drains.



METROPOLITAN RIO DE JANEIRO, SHOWING ITS PRINCIPAL STREETS, BEACHES



PUBLIC BUILDINGS AND PARKS, AND ALSO THE TOPOGRAPHY OF THE AREA

Buildings.—There remain many public edifices and dwellings of the colonial period, severely plain in appearance, with heavy stone walls and tile roofs. The old city palace facing upon Praça 15 de Novembro, once the residence of the fugitive Portuguese sovereign Dom John (João) VI, is an example. The 19th century brought no important modifications until near its close, when French and Italian styles began to appear, both in exterior decoration and in architectural design. The Praça do Comércio (merchants' exchange) and post office on Rua 1° de Março are notable examples. After that time architectural styles changed radically, and apartments, hotels, office buildings and public buildings of the most advanced modern design and construction were built. At the southern end of the Avenida Rio Branco is a group of elegant state edifices, the Municipal theatre, the Monroe palace and the National library and Academy of Fine Arts. The buildings of the ministries of finance, education and war are also among the most beautiful in the city. There are more than 200 churches in the city, including the cathedral which was built in 1761. The most noteworthy church is that of Our Lady of Candelária, in the commercial district, with twin towers and graceful dome.

Hospitals and Asylums.—Rio de Janeiro has a number of hospitals, asylums and benevolent institutions. Chief of these is the Misericórdia hospital, popularly known as the "Santa Casa," belonging to a religious brotherhood dating from 1591. Other public hospitals are a lepers' hospital in São Cristóvão, the military and naval hospitals, the São Sebastião hospital and the isolation and contagious diseases hospitals in Jurujuba. The government participated in a program of remodeling and improving existing institutions and of building such new ones as the Jesus, Miguel Couto and Getúlio Vargas hospitals. There are also a number of private hospitals maintained by church brotherhoods and charitable associations; among them are the Portuguese hospital in Rua de Santo Amaro and the Strangers' hospital in Botafogo. Most prominent among the asylums is the Hospício Nacional for the insane, which was erected in 1842–52.

Education.—Rio de Janeiro was always an important educational centre. A Jesuit school (*colégio*) transferred there in 1567 was a foremost institution of pre-university training for almost two centuries. The 19th century saw the creation of a "model" secondary school, the Colégio Dom Pedro II (1837), as well as military (1838), naval (1858) and engineering (1874) schools. The military school became famous as a stronghold for the positivist ideology which influenced the republican *coup d'état* of 1889. In 1920, Brazil's adoption of the university system was marked by the creation of the University of Rio de Janeiro. An educational reform program inaugurated in the Federal District in 1928 made the city the focus for a renovation of pedagogical ideas and techniques which affected the whole country. As part of this reform, a presidential decree of 1931 created faculties of education, sciences and letters. At the same time, such pre-existing institutions as the schools of law, medicine, pharmacy, dentistry, mines and fine arts, the Polytechnic school, the National museum, the Geological and Mineralogical institute, the Oswaldo Cruz institute (medical research), the Astronomical observatory, the Institute of Chemistry, the Botanical garden, the Institute of Legal Medicine, the Central Meteorological institute and other centres of higher learning were made integral parts of the university. Considerable progress was made in the field of teacher training, which was climaxed in Rio de Janeiro by the creation in 1935 of the University of the Federal District—comprising the teachers' college, schools of letters, sciences, economics and law and an institute of arts. In 1939 this institution was merged with the University of Brazil, as the University of Rio de Janeiro had been renamed two years earlier. A Catholic university was founded in the city in 1940.

In addition to its two universities, Rio de Janeiro has many other institutes of learning, including preparatory schools, vocational schools and schools for the deaf and blind.

Harbour, Communications and Commerce.—The port and harbour of Rio de Janeiro are the largest in the republic. The entrance is open to vessels of the largest draught, and there is sufficient deepwater anchorage inside for the navies of the world. The lower anchorage, where the health officers visit vessels, is below Ilha Fiscal, and the upper or commercial anchorage is in the broad part of the bay above Ilha das Cobras, the national coasting vessels occupying the shallower waters near the Saúde and Gamboa districts. The customhouse occupies a considerable part of the shore line before the old city.

The newer port works consist of an improved water front for the Saúde, Gamboa and Saco do Alferes districts, in which the shipping interests are centred, and a continuation of the sea wall across the shallow São Cristóvão bay to the Ponta do Cajú, the large reclaimed area being filled in by the removal of some small hills. The commercial quays are built in deep water and permit mooring alongside the largest vessels. The total length of the commercial quays is about 7,500 yd. Railway and streetcar connections are provided, and both electric and hydraulic power are available. Special surtaxes are levied on imports to meet the interest and redemption charges on the loans raised for the execution of these important works.

Railway communication with the interior is maintained by the Central do Brasil and the Leopoldina lines, besides which there is a short passenger line to Corcovado mountain about two and one half miles long, an electric line to Tijuca and a narrow-gauge line to the Rio do Ouro waterworks. There is communication with Petrópolis by a branch line of the Leopoldina system, and also by a steamer to the head of the bay and thence by rail up the *serra*.

Rio de Janeiro is the seaport for a large area of the richest, most productive and most thickly settled parts of Brazil, including the states of Rio de Janeiro and Minas Gerais and a small part of eastern São Paulo. Its exports include coffee, sugar, hides, cabinet woods, tobacco and cigars, tapioca, gold, diamonds, iron ore, manganese and sundry small products.

The city is also a distributing centre in the coasting trade, and many imported products, including jerked beef (*xarque*), hay, flour and wines, appear among the coastwise exports, as well as domestic manufactures. Formerly Rio de Janeiro led all other ports in Brazil in the export of coffee, but the enormous increase in production in the state of São Paulo later gave Santos the lead.

Air travel is of increasing importance for the city's communication with other coastal cities and with the vast hinterland of Brazil, as well as with the rest of the world. Rio de Janeiro is served by two airports, Santos Dumont and Galeão.

Manufactures.—In spite of Rio's leading role as a commercial port, the city is not equally important as an industrial or manufacturing centre. Manufactures consist largely of consumers' goods for the domestic market, and include such items as flour (from imported wheat), biscuits, macaroni, chocolate, fruit conserves, refined sugar, confectioneries and other foodstuffs, beer, liquors, ice, mineral waters, cigars and cigarettes; soap, candles, perfumes, furniture, boots and shoes, hats, clothing, rope, matches, ink, printing type, glass, chemicals and tires. In addition there are plants which manufacture finished products from processed imports, especially drugs and sundries. There are machine and repair shops, notably the shops of the Central do Brasil railway. One of the most important industrial enterprises in the city is that of the Rio de Janeiro Tramway, Light and Power Co., whose generating plants are located about 50 mi. from the city. In the mid-1960s there were more than 4,000 industrial establishments employing about 200,000 persons. Promotion of trade in the city is largely a function of the chamber of commerce of Rio de Janeiro and the Federation of Brazilian Chambers of Commerce.

Government.—Until it became the state of Guanabara in 1960, the Federal District, including Rio de Janeiro, was governed by a prefect, representing the national government, and a municipal council, representing the people. The prefect was appointed by the president of the republic for a term of four years, subject to confirmation by the senate. There were seven *diretorias*, or boards, under the prefect, each one assigned to a special field of work, chief among them being education, public health and social welfare, public works and transportation, finance, police, archives and statistics, forestry, and game and fishing. The municipal council of *intendentes* was elected by direct suffrage for a term of two years and was composed of 50 members meeting in

ordinary session twice a year. In April 1960, a national law ordered the election, the following October, of a governor for the new state of Guanabara and a legislative assembly that would meet during its first four months as a constituent body.

History.—It has been said that the Bay of Rio de Janeiro was discovered by André Gonçalves and Amerigo Vespucci on Jan. 1, 1502, and that Gonçalves named it "River of January." More probably it was discovered in 1504 by Gonçalo Coelho. The name "Rio de Janeiro" appeared on maps only in about 1515. Another Portuguese navigator, Martim Afonso de Sousa, visited the bay in 1531, but passed on south to São Vicente, where he established a colony. The first settlement in the bay was made by an expedition of French Huguenots under the command of Nicolas Durand de Villegaignon, who established his colony on the small island that bears his name. The French called their colony La France Antarctique, and the island stronghold Fort Coligny. In 1560 the fort was captured and destroyed by a Portuguese expedition from Bahia under Gov. Mem de Sá, and in 1565 another expedition under Estácio de Sá, cousin of the governor, founded a Portuguese settlement in another part of the bay which was called São Sebastião do Rio de Janeiro, in honour of King Sebastian of Portugal. Two years later the French were decisively defeated by Mem de Sá, who moved the settlement to the hill later known as the Morro do Castelo. He laid out streets and a plaza, and encouraged construction of the first houses. The following governor built a sugar mill on the island that is still called the Ilha do Governador. Twice during the next hundred years Brazil was divided for short periods into two governorships, with Rio serving as capital of the southern jurisdiction. In 1710–11 the French made two expeditions against Rio and finally withdrew after exacting a heavy ransom.

The discovery of gold in Minas Gerais at the end of the 17th century greatly increased the importance of Rio de Janeiro. During the governorship of Gomes Freire de Andrade (1733–63) the Carioca aqueduct, the governor's palace, the convent of St. Teresa and other architectural landmarks were built; fortifications were strengthened; urbanism and public health received attention; intellectual life was encouraged; and Brazil's first printing press was established. In 1763 Rio succeeded Bahia as the capital.

In 1808 the Portuguese court, under the regent John (Dom João) took refuge in Rio de Janeiro and gave a new impulse to its growth. It was thrown open to foreign commerce, foreign mercantile houses were permitted to settle there, printing was permanently established, industrial restrictions were removed and a college of medicine, a military academy and a public library were founded. John VI returned to Portugal in 1821, and on Sept. 7, 1822, Brazil was declared independent with Dom Pedro I as its first emperor and Rio de Janeiro as its capital. In 1834 Rio became an autonomous municipality and was declared capital of the empire. In 1839 a steamship service along the coast was opened, but direct communication with Europe was delayed until 1850 and with the United States until 1865. These services added largely to the prosperity of the port. The first section of the Dom Pedro II railway was opened in 1858, and the second or mountain section in 1864, which brought the city into closer relations with the interior. In 1874 cable communication with Europe was opened, which was soon afterward extended southward to the river Plate republics.

During the five years following the declaration of the republic in 1889 life in Rio de Janeiro was interrupted by political disorders, particularly by a six-month blockade of the port and desultory bombardment. Under the presidency of Francisco de Paula Rodrigues Alves (1902–06), however, the problems arising from the city's narrow, congested streets and deplorable health conditions were attacked in a co-ordinated effort led by Lauro Müller (federal minister of industry), Pereira Passos (city prefect) and the physician Dr. Oswaldo Cruz. The avenues, parks and port facilities for which Rio is famed were planned, while the diseases of yellow fever, bubonic plague and smallpox were eliminated or greatly reduced. Until 1930 Rio was the scene of a number of political outbreaks, notably the short-lived revolt of the army officers of Fort Copacabana in 1922, but none was of great importance. Under the first regime of President Getúlio Vargas (1930–45) and thereafter the rapid expansion of the government bureaucracy and the congestion and overbuilding of Rio de Janeiro gave impetus to plans, dating from even before the republican period, for moving the national capital to an inland site that would enjoy a cooler climate and be a stimulant for opening up Brazil's unexploited hinterland. President Juscelino Kubitschek (1956–61) resolved to effect the transfer during his administration and sanctioned a law for the construction of the new capital, Brasília, 600 mi. N.W. of Rio. The official change of capitals took place on April 21, 1960. *See* also references under "Rio de Janeiro" in the Index. (R. M. M.)

RÍO DE ORO, the name commonly used for all of Spanish Sahara (*q.v.*) on the northwestern coast of Africa, but strictly applicable only to the southern two-thirds of the territory, between Cap Blanc (Blanco) and Cape Bojador. The northern part of Spanish Sahara, Saguia el Hamra, extends to near Cape Yubi (Juby). (R. J. H. C.)

RIO GRANDE (Rio Grande do Sul), a port in the state of Rio Grande do Sul, Braz. It is located on the western side of the Rio Grande, the name also given to the wide outlet to the Atlantic of the Lagôa dos Patos. The city is built on a low peninsula, barely 5 ft. above sea level, and about 8 mi. upstream from the mouth of the river. Pop. (1960) 83,189.

The peninsula on which Rio Grande has been built is a part of a long sand bar extending from north of Pôrto Alegre southwestward into eastern Uruguay. Cut off from the ocean by the bar are several shallow lagoons, the largest of which are Lagôa dos Patos and Lagôa Mirim. For hundreds of miles on either side of Rio Grande the ocean is bordered by a smooth, sandy beach, backed by strings of live sand dunes, in many ways similar to the coast of southern Georgia. The outlet of the lakes in back of the bar is located at the southern end of Lagôa dos Patos. Where the river enters the ocean it passes over a submerged bar which once limited passage to ships of 26 ft. draft or less. The bar was dredged and the channel is kept open so that ocean-going vessels of larger size can dock at Rio Grande or Pelotas, 20 mi. N.N.W.

Rio Grande was founded in 1737 by José da Silva Paes, who built a fort on the river near the site of the present city and called it Estreito. In 1745 the garrison and settlement were removed by Gomes Freire d'Andrade to its present site, which became a *vila* in 1751, with the name of São Pedro do Rio Grande, and a *cidade* (city) in 1807. It was the capital of the captaincy until 1763, when it was occupied by a Spanish force from Buenos Aires under the command of Don Pedro Zeballos. The seat of government was then removed to Viamão at the northern end of the Lagôa dos Patos. The city was occupied by the national forces in the ten years' war of secession, which began in 1835, and in 1894 it was unsuccessfully besieged by a small insurgent force that attempted to overthrow the government at Rio de Janeiro.

Rio Grande competes with Pelotas as the outlet for the products of Rio Grande do Sul. As the outport for Pôrto Alegre, with which it is connected by shallow-draft lake boats, Rio Grande has an advantage; but for the products of the south, Pelotas is better situated. The exports, mostly to other parts of Brazil, include jerked beef (*xarque*), hides, lard, tallow, wool, rice, wheat and fish. In the city are factories processing meat products, fish and vegetable canneries, a woolen textile mill, breweries, cigarette manufactures and a shoe factory. The city is linked with Pelotas by rail. A rail line also extends 12 mi. south to a bathing beach and casino. (P. E. J.)

RIO GRANDE, the fifth longest North American river, forms the southwestern boundary of Texas. From its sources in the snow fields and alpine meadows of the San Juan mountains of southwestern Colorado, it flows southeast and south 175 mi. in Colorado, southerly about 470 mi. across New Mexico, and southeasterly between Texas and the Mexican states of Chihuahua, Coahuila, Nuevo León and Tamaulipas, for about 1,240 mi. to the Gulf of Mexico. The total length is approximately 1,885 mi.

It starts as a clear Rocky mountain stream, fed by springs at an elevation of more than 12,000 ft., then flows in a canyon through forests of spruce, fir and aspen, into the broad San Luis

valley in Colorado, after which it cuts the Rio Grande gorge and White Rock canyon and enters the open terrain of the basin and range and Mexican highland physiographic provinces. There declining elevation, decreasing latitude and increasing aridity and temperature produce a transition from a cold steppe climate with a vegetation of piñon, juniper and sagebrush, to a hot steppe and desert climate characterized by a vegetation of mesquite, creosote bush, cactus, yucca and other desert plants. Shortly before entering the Gulf coastal plain, the Rio Grande cuts three canyons between 1,500 and 1,700 ft. in depth across the faulted area occupied by the "big bend" where the Texas side of the river is included in the Big Bend National park. In the remainder of its course the river wanders sluggishly across the coastal plain to end in a true delta in the Gulf of Mexico.

The principal tributaries are the Pecos and Devils rivers from the left bank in the United States, and from the right bank the Chama and Puerco in the United States and the Conchos, Salado, and San Juan in Mexico. The basin contains about 172,000 sq.mi. The peak of flow may occur in any month from April to October, but in the upper reaches it usually is in May or June due to melting snow and occasional thunderstorms, while the lower portion commonly has highest water in June or September due to summer rain storms. It has been estimated that the Rio Grande has an average annual yield of more than 9,000,000 ac.ft. of which about one third reached the gulf before the building of the Falcón dam in 1953.

Irrigation has been practised in the Rio Grande basin since prehistoric times, as among the Pueblo Indians of New Mexico. Increase in population and in use of water made necessary the 1905–07 and 1944–45 water treaties between the United States and Mexico, as well as the Rio Grande compact (1939) among Colorado, New Mexico and Texas concerning the waters of the upper Rio Grande sub-basin (above Ft. Quitman, Tex.), and the Pecos river compact between New Mexico and Texas (1948) concerning the Pecos above Girvin, Tex. Essentially all of the average annual production of more than 3,000,000 ac.ft. in the upper Rio Grande (including the 60,000 ac.ft. allotted to Mexico by treaty) is consumed within this sub-basin. Not only below Ft. Quitman, but in many stretches of the river from the New Mexico-Colorado border to below Brownsville there has been no surface flow at various times. In some places the depth has varied from nearly 60 ft. to a bare trickle or nothing. The lower Rio Grande (below Ft. Quitman) is renewed by the Conchos and other Mexican rivers which produce about two-thirds of the available water. A number of large springs in the area between Hot Springs and Del Rio, Tex., including many in the bed of the river, are important and dependable producers of water. The total storage capacity of the reservoirs in the basin is about 13,000,000 ac.ft., with a normal storage of less than 5,000,000 ac.ft., chiefly in the International Falcón reservoir on the lower Rio Grande, Lago Toronto (La Boquilla) on the Conchos, Elephant Butte on the Rio Grande in New Mexico, Marte Gómez (El Azúcar) reservoir on the San Juan and Venustiano Carranza (Don Martín) on the Salado. About 3,000,000 ac. are irrigated within the basin (about two-thirds of these are in the U.S.). The leading crops raised by irrigation vary from potatoes and alfalfa in Colorado to cotton, citrus fruits and vegetables in the valley of the deltaic lower Rio Grande in Texas and Tamaulipas.

After agriculture and animal husbandry, the leading industries are mining (petroleum, natural gas, coal, silver, lead, gold, potash, gypsum, etc.), and recreation (national and state parks and monuments, dude ranches, fishing and hunting, summer and winter resorts, etc.). More than 3,000,000 people live in the basin, principally in urban communities, the largest of which are Monterrey, Mex.; Ciudad Juárez, Mex.; El Paso, Tex.; Albuquerque, N.M.; Chihuahua, Mex.; Saltillo, Mex.; Matamoros, Mex.; Nuevo Laredo, Mex.; Laredo, Tex.; and Reynosa, Mex.

During the Spanish period the middle and upper portions commonly were termed the Río del Norte or Río Grande del Norte and the lower course usually was called the Río Bravo (apparently because of the turbulent flash floods). The river is officially the Rio Grande in the U.S. and the Río Bravo del Norte in Mexico. The earliest European settlements were in the Conchos basin of Chihuahua in the 16th century, but many of the Pueblo Indian settlements of New Mexico date back to before the Spanish conquest. Small steamboats were used for navigation on the lower Rio Grande up to Rio Grande City, and even to Roma when the river was high, from the 1850s until the great hurricane of 1874 swept the river clean. Since then accelerated erosion, silting and sand-bar formation have precluded navigation, and have forced the U.S. and Mexico to spend much money and time in adjusting the boundary to the numerous changes in the river channel. There has been considerable development of hydroelectricity within the basin.

(D. D. B.)

RIO GRANDE DO NORTE, a state in the northeast of Brazil, bounded by the Atlantic Ocean on the north and the east, by the state of Paraíba on the south, and by Ceará on the west. Area 20,469 sq.mi., pop. (1960) 1,157,258. The state capital is Natal (*q.v.*); the only other town of importance is Mossoró.

Except for the coastal strip from Natal southward, which receives adequate rainfall to support a forest, the state is semi-arid. It was originally covered with a deciduous, thorny, scrub woodland (*caatinga*). The northern coast, beyond Cape São Roque, is low and sandy, but the land rises inland to some low mesas (*taboleiros*). Inland from Natal, along the southern border of the state, is the northern edge of the Borborema, a hilly upland with rounded slopes and steep margins. The Apodi, the Piranhas, and the Potengi rivers rise in the Borborema and flow northward across the state.

The first settlement was near Natal in 1599. The Dutch held this region for 25 years in the 17th century. Because of semi-arid conditions the land was useful mostly for the grazing of cattle and goats, but from Natal southward some sugarcane was and still is grown. Carnauba wax is produced in the western part of the state and cotton is grown in the south. The Borborema is known to contain a number of slightly exploited rare minerals —including beryl, diatomite, columbite, and tantalite.

(P. E. J.)

RIO GRANDE DO SUL, the southernmost state of Brazil, is bounded on the north by Santa Catarina state, on the east by the Atlantic Ocean, on the south by Uruguay, and on the west by Argentina. The Uruguay River (*q.v.*) forms the boundary on the west. Area 108,951 sq.mi., including inland waters; pop. (1960) 5,448,823.

Physical Geography.—In the north, the state occupies the southern part of the Paraná plateau. This highland, which extends from southern São Paulo state to the middle part of Rio Grande do Sul and which crosses the border into Argentina and Paraguay, is made up of a succession of outpourings of dark-coloured basaltic lava now solidified into sheets of rock known as diabase. The surface of the plateau stands between 2,000 and 3,000 ft. above sea level. Along the streams it was dissected into a rolling hilly country, but because of the resistance of the diabase its margins are everywhere marked by steep cliffs or *cuestas.* In Rio Grande do Sul the diabase cliffs cap the southern extremity of the Great Escarpment (the eastern edge of the Brazilian highland) along the Atlantic coast almost as far south as Pôrto Alegre. Just north of this city, however, the diabase cliffs turn westward and form a sharply marked descent facing to the south along the northern side of the Jacuí valley. The southern half of Rio Grande do Sul is much lower. The Jacuí River drains a lowland along the base of the plateau, flowing into the northern end of the Lagôa dos Patos near Pôrto Alegre. South of the Jacuí there are gently rolling hills, standing only some 1,000 to 1,500 ft. above sea level and extending across the border into Uruguay. West of Livramento the land forms are tabular rather than rounded, for here the diabase continues southward into western Uruguay, but at a much lower elevation than on the Paraná plateau to the north. The Uruguay River cuts through the diabase, its course frequently interrupted by rapids. All along the im-

mediate Atlantic coast there are long sand bars and lagoons, the largest of which are Lagôa dos Patos and Lagôa Mirim.

Climate.—Rio Grande do Sul is far enough south to experience mild winters, but sometimes with freezing temperatures. At this time of the year cold air masses from the south pass by at frequent intervals, bringing heavy rains along their fronts. Occasionally colder winters bring snow to the higher elevations. In summer, the winds from the northeast prevail and there is less rain. Hot weather prevails, especially inland from the open ocean. Although the whole state has abundant rainfall, the prevailing vegetation cover is that of a tall-grass prairie. Forests occur only along the steep slopes of the Great Escarpment, along the south-facing margin of the Paraná plateau and along the deeper valleys that are cut into the plateau.

The Economy.—There are four chief agricultural regions in Rio Grande do Sul. The first is the oldest—the zone of large cattle and sheep ranches which lies south of the Jacuí River and extends almost unbroken to the borders of Uruguay and Argentina. This is the domain of the Gauchos, the herdsmen whose cattle and sheep feed on the unimproved pastures. The beef produced is lean and tough, the kind chiefly required for the manufacture of *xarque* or jerked beef (sometimes called *carne seca*) which is eaten by the poorer Brazilians; it is also the beef most desired by the people of Italy who import it directly from this region. The second region from south to north is the flood plain of the Jacuí River, and of its northern tributary, the Taquarí. It supports a dense population of Brazilians of Portuguese descent. The main product is rice. The properties are large, and each owner provides his own irrigation and drainage. The river floods in winter, but there is usually enough moisture left to support the rice crop during the following summer. The better estates are equipped with pumps to raise water from the river during the summer. The Jacuí valley produces something like 25% of the Brazilian rice crop, a crop that is consumed partly in Pôrto Alegre, but chiefly in the large cities of Rio de Janeiro and São Paulo. The third agricultural region is the zone of the German colonies, located on the terraces above the Jacuí valley and on the lower slopes of the Paraná plateau. Maize, rye, and wheat are raised here, and maize is fed to hogs. Around Santa Cruz is one of Brazil's chief tobacco-growing areas. The fourth region is higher up on the plateau—the Italian colonies with their vineyards. Each of the four regions is strikingly different not only in agriculture, but also in rural landscape, kinds of roads and buildings, and in traditions of the people.

On the plateau top large tracts of land are still used for pasture, but since 1940 there has been a considerable increase of wheat farming. In the forests of the Uruguay valley there is pine to be cut for timber, and also the leaves of the Maté which are collected and roasted to prepare the beverage known as maté, or Paraguay tea, widely used through south Brazil and the neighbouring countries.

Coal of an inferior quality is mined at São Jerônimo, just south of the Jacuí River a short distance upstream from Pôrto Alegre, to which it is shipped by river barge. The coal contains so much sulfur and other impurities that special grates must be used to burn it. In Pôrto Alegre, however, the cost of bringing in better coal is so great that the local product is used to manufacture gas and to generate electricity.

The principal industries of the state are concentrated at Pôrto Alegre (*q.v.*), the state capital, and the outports Rio Grande and Pelotas (*qq.v.*). Bagé, Santa Maria, Uruguaiana (*qq.v.*), and Livramento are important towns of the interior.

History.—The Rio Grande area, the so-called "Mission" country, was a zone of conflict between the Portuguese and Spanish. The open grasslands were entered both by Portuguese coming from São Paulo and by Spaniards from Buenos Aires, but neither group established settlements except for forts at key positions around the edge. Seven Jesuit missions were established along the Uruguay River between 1632 and 1707 and the scanty Indian population was gathered together around these places. In 1737 the Portuguese established a fort near the present site of Rio Grande, and in 1738 a large extent of territory which included the present states of Santa Catarina and Rio Grande do Sul, and a part of Uruguay, was named the captaincy of El Rei, to be administered from Rio Grande. But the Spaniards resented the proximity of Portuguese settlements to what they considered their domain and from 1763 to 1776 they occupied Rio Grande. The Portuguese moved their administration centre to the northern end of Lagôa dos Patos, first to Viamão, then to Pôrto dos Cazães which was renamed Pôrto Alegre.

When Brazil declared its independence in 1822, its territory extended southward to the shores of the Río de la Plata. But the Argentines promptly invaded and were in process of pushing the Portuguese back, when, in 1828, Great Britain succeeded in getting the warring countries to agree to the existence of an independent Uruguay. The boundary between Rio Grande do Sul and both Uruguay and Argentina was then fixed. In 1865 a Paraguayan army captured Uruguaiana and held it for a month or so. To this day the Brazilian army spends much of its time training to protect this southern frontier.

In 1822 Emperor Dom Pedro I realized that if this southern territory was to be secured for Brazil, colonies should be established there. In 1824 a small group of German peasants and craftsmen was settled at São Leopoldo (*q.v.*), just to the north of Pôrto Alegre. By the time of independence all the open grasslands were divided into large private properties for use as cattle and mule ranches. The Portuguese were never attracted by forested country; it was German pioneers who occupied the forests. Between 1824 and 1859 more than 20,000 Germans were settled on small farms along the lower slopes of the plateau to the west of São Leopoldo. They planted rye and potatoes, and grew maize to feed to hogs—an agricultural procedure unknown to the Portuguese. The farm products were sent to Pôrto Alegre by boat on the Jacuí River. Between 1870 and 1890 a large group of Italian pioneers came to Rio Grande do Sul, and these settled above the German settlements, along the upper slopes of the plateau, especially around the town of Caxias. The Italians introduced vineyards and made wine.

Rio Grande do Sul, because of its position on the edge of the Brazilian nation, has often tried to secede. In 1835 a war of secession broke out which lasted for ten years. The state was kept a part of Brazil less by military force than by gifts from the federal treasury. Under Dom Pedro II, who ruled Brazil until 1889, even the more remote states were made to feel contented. But in 1892, during the presidency of Floriano Peixoto, too much interference with the state government led again to insurrection in the south. The revolutionaries carried the war northward even as far as Curitiba, but were forced to surrender in 1894 because of the lack of munitions. In 1930, the revolt led by Getúlio Vargas against the domination of São Paulo started in Rio Grande do Sul. (P. E. J.)

RIOJA, FRANCISCO DE (1583–1659), Spanish poet and scholar born in 1583 in Seville, is celebrated particularly for his poems on flowers, symbolizing different aspects of the transience of beauty; the attribution to Rioja of the *Epístola moral a Fabio* and of Rodrigo Caro's *Canción a las ruinas de Itálica* is discarded. Rioja's fastidious sobriety of style, his Horatian tone of epicurean Stoicism, and certain thematic constants approximate him to such older Seville contemporaries as his friend Francisco de Medrano (*q.v.*) and Juan de Arguijo. As a protégé of the count of Olivares (*q.v.*), he followed him into banishment, retiring after his death to Seville and only returning in 1654 to Madrid, where he died in 1659.

See *Poesías de Francisco de Rioja*, ed. by C. A. de la Barrera (1872); A. Lumsden, "Francisco de Rioja" in *Spanish Golden Age Poetry and Drama*, ed. by E. A. Peers (1946). (F. S. R.)

RIOJA, LA: *see* La Rioja.

RIOM, a town of central France and a subprefecture in the *département* of Puy-de-Dôme, 13 km. (8 mi.) N of Clermont-Ferrand by road. Pop. (1962) 13,473. The Ricomagus or Ricomum of the Romans, Riom was seized, along with Auvergne, for the crown by Philip II. Thereafter it became the capital of the provincial administration of Auvergne. The town stands on the Ambène River, on the western edge of the fertile Limagne

Basin. It has a distinctive beauty; the houses, some dating from the 15th and 16th centuries, are built of gray lava. The church of Saint-Amable (Romanesque and Early Gothic, restored) dates from the 12th century; that of Notre-Dame-du-Marthuret (14th–15th centuries) has a well-known statue of the "Virgin with Bird." The Sainte-Chapelle of the 14th and 15th centuries is a relic of the palace of Jean de France, duc de Berry. The rest of the site of the palace is occupied by the law courts. The court of appeal for four *départements,* Allier, Cantal, Puy-de-Dôme, and Haute-Loire is at Riom. There, in February–April 1942, the trial of French political leaders (including Édouard Daladier, Léon Blum, and Maurice Gamelin) took place at the supreme court of justice set up by the Vichy government. The F. Mandet Museum and the small Jeanne d'Arc Museum (in the *hôtel de ville*) are of particular interest. (P. M. Sa.)

RÍO MUNI is a river flowing into the Bight of Biafra, West Africa, just north of the Equator. It is also the name of the territory of continental Equatorial Guinea within which the river flows, and which adjoins the republics of Cameroon and Gabon. This territory includes the estuary islets of Corisco, Elobey Chico, and Elobey Grande. *See* Equatorial Guinea. (R. J. H. C.)

RÍO NEGRO, a province of Argentina lying within the wind-swept region generally referred to as Patagonia (*q.v.*). It was created a territory of the republic in 1884 and was raised to the status of a province in 1955. It stretches from the Atlantic coast to the Chilean frontier in the Andes. Pop. (1960) 193,848. Area 78,383 sq.mi.

The land between the Colorado and Negro rivers is similar in formation and characteristic to the "dry pampas"; but a great dam was built on the Negro River near Neuquén, making possible the irrigation of a large district and the growing of alfalfa (lucerne) for cattle fodder and the planting of extensive fruit orchards, particularly pears and apples, which have earned fame for the province. The other important occupation is sheep breeding.

South of the Negro River most of the country consists of a series of arid tablelands, but there are several chains of lakes in the forested valleys of the Andes that are held to rival Swiss scenery. The principal lake is Nahuel Huapí, which lies partly in the province of Neuquén (*q.v.*).

The Atlantic coastline has one deep indentation, the Gulf of San Matías, in the northern bend of which is the little port of San Antonio Oeste. The provincial capital is Viedma on the right bank of the Negro River about 20 mi. from its mouth and opposite Carmen de Patagones, a port of the province of Buenos Aires. There are numerous small settlements along the Negro River valley and on the railway that runs inland from San Antonio Oeste, but the only other town of importance is San Carlos de Bariloche, a holiday resort consisting of hotels and wooden chalets picturesquely situated among trees on the shore of Lake Nahuel Huapí. Bariloche is one of the two terminals of the railway from San Antonio. It can also be reached by road from Buenos Aires (1,200 mi.) and by air. (Ge. P.)

RÍO NEGRO, a riverside department, established 1880, in west Uruguay. Area 3,271 sq.mi., pop. (1963) 46,741. Its rich pastures are used to fatten livestock from northern Uruguay and from Argentine areas across the Uruguay River. The only industrial town is the departmental capital, Fray Bentos (*q.v.*); an important meat packing and canning centre. Wheat is the principal farm crop, but sunflower seeds, flax, corn, fruits, and vegetables are also grown. (M. I. V.)

RIONI, a river in the Georgian Soviet Socialist Republic, U.S.S.R., is 179 mi. (288 km.) long and drains a basin of 5,200 sq.mi. (13,500 sq.km.). It rises just south of the crest line of the main Caucasus range and cuts the southern ranges and foothills of the Caucasus in a series of deep, narrow, and highly picturesque gorges. At Kutaisi it emerges from the mountains and flows westward across the flat Rioni or Kolkhida lowland (the legendary land of the Golden Fleece) to enter the Black Sea at Poti. The Rioni receives a large number of tributaries draining the western part of the Greater and Lesser Caucasus. These rapid mountain streams bring huge quantities of silt, which are deposited in the Kolkhida lowland and have created extensive swamps, where reclamation has been in progress since World War II. The major tributaries are the Dzhodzhara and Kvirila on the left and the Tskhenis-Tskali and Tekhuri on the right. Average annual discharge at Poti is 14,550 cu.ft. per sec. The greater part of the mountain section of the river is followed by the Ossetian Military Highway across the main Caucasus to Kutaisi. There is a series of hydroelectric plants on the Rioni and its tributaries, the largest being at Kutaisi. (R. A. F.)

RÍO PIEDRAS, a former city, which has been incorporated into the sprawling metropolis of San Juan (*q.v.*), the capital of Puerto Rico. Pop. (1950) 143,989.

Río Piedras is the home of the University of Puerto Rico and its very active commercial life is directed to the servicing of 14,000 university students. It is connected with San Juan by modern throughways, and from Río Piedras highways branch out to the coastal cities of the east and the interior towns of Caguas and Humacao. (T. G. Ms.)

RÍO SAN JUAN, a department in southeastern Nicaragua, adjoining Costa Rica. Pop. (1963) 15,676; area 2,876 sq.mi. San Carlos, pop. (1963) 6,076 (mun.), departmental capital and largest town, is at the junction of Lake Nicaragua and San Juan River. Although San Juan del Norte (*q.v.*) is no longer an ocean port, small steamers use the San Juan River between Lake Nicaragua and the Caribbean. The people of the department are concentrated mostly between the central highlands and Lake Nicaragua, where they are engaged chiefly in raising livestock and growing corn, rice, beans, cassava, other vegetables, and tropical fruits. (C. F. J.)

RIOT, in general terms, is a temporary violent outbreak of civil disorder, falling short of an attempt to overthrow the government, and thereby distinguished from insurrection or rebellion. As a legal concept, riot has a more limited meaning: it is a criminal offense against public order involving a group, however small, and the use of violence, however slight. In some countries, the gravamen of the offense is the breach of peace occasioned by it. That is notably the case in the criminal law of England and of the United States. In other countries, such as those under the continental codes, the offense requires interference with or resistance to public authority.

At common law, there are three offenses which, in ascending order of seriousness, involve group breaches of the peace: unlawful assembly, rout and riot. An assembly of persons is unlawful if the participants share a common illegal purpose, regardless of whether steps are taken to effect that purpose. Rout is a kind of way station between unlawful assembly and riot: it consists of an unlawful assembly which has taken some step, short of actual violence, to put its illegal purpose into operation.

Rout becomes riot when violence is used. Riot has been judicially stated to consist of the following elements: (1) the presence of three or more persons; (2) a common unlawful purpose; (3) the execution or inception of the common purpose; (4) an intent to help one another by force if necessary against any person who may oppose them in the execution of their unlawful purpose; (5) force or violence not merely used in demolishing, but displayed in such a manner as to alarm at least one person of reasonable firmness and courage.

A person is guilty of riot if he shares the common unlawful purpose of the assembly and has the requisite intent to use force if necessary, regardless of whether he himself has used force once actual force has been used or threatened by others. The concept is obviously a broad one, capable of embracing a wide range of group conduct from a bloody clash between picketers and strikebreakers to the antics of a street-corner gang.

At common law, riot was an indictable misdemeanour, punishable by fine and imprisonment. In England the Riot act of 1714 made it a felony under certain circumstances of aggravation. The act was passed in response to the widespread rioting which attended the accession to the throne in that year of the first Hanoverian king, George I. Under its provisions, as subsequently modified, whenever an unlawful assembly of twelve or more persons (as contrasted with the three or more required for the com-

mon-law misdemeanour) fail to disperse within an hour after a magistrate has read or tried to read a proclamation, couched in language prescribed by the statute, directing them to disperse, those present cease to be merely misdemeanants and become guilty of a felony, punishable by life imprisonment. The procedure of reading the proclamation came to be known, inaccurately but inevitably, as "reading the riot act," a phrase which has enriched the language in situations far removed from its original meaning. An oddity of the law is that the proclamation must be read verbatim in the prescribed language; otherwise the prosecution fails. A conviction was quashed on this ground in 1830 because the proclamation omitted the concluding words "God save the King."

In spite of the severe penalties prescribed by the Riot act, there are several well-known instances of riots in England subsequent to 1714, including the Gordon anti-Catholic riots of 1780, the Bristol riots of 1831 and the Chartist riots of 1839.

Other provisions of English criminal law impose punishment for various harms to property committed in the course of a riotous assembly and prescribe various rights and duties arising out of the occurrence of a riot. For instance, the law imposes on magistrates the duty of assembling subjects of the realm, whether civil or military, for the purpose of quelling the riot. It is the magistrate's duty to keep the peace; if the peace is broken, honesty of intention will not avail him if he has been guilty of neglect of duty. A somewhat unsettled question is the extent of the protection afforded at common law and by the Riot act to persons acting under orders for the suppression of riots. Although, as just stated, the law of England requires everyone to aid the magistrates in the suppression of riotous assemblages, the degree of force which may be used in effecting that end depends on the nature of the riot. The use of deadly force can only be justified where lesser measures are inadequate to prevent the commission of violent felonies. These rather vague rules apply to soldiers and civilians alike. A matter of some importance is the availability of a civil remedy for persons whose property has been damaged by riot. Under the Riot Damage act of 1886, compensation is payable out of the taxes levied for police maintenance in the district where the riot occurred. Thus a form of public liability for riot damage is provided.

In the United States, laws relating to riot have in general followed the common-law view, at least to the extent of focusing upon the disturbance of the peace rather than the resistance to public authority as the gravamen of the offense. The major difference between English and U.S. law is that the typical U.S. provision on this subject imposes comparatively mild penalties.

The old common-law distinctions among unlawful assembly, rout and riot are preserved in the laws of some states. Others have created a consolidated offense. Aggravated penalties are commonly provided for failing to disperse after having been called upon by a public authority to do so; but the formal requirements of the English Riot act are not often imposed. Inciting to riot is in some states made a separately punishable offense. Some states have adopted the English view that reparation should be made out of public funds to persons whose property has been damaged or destroyed in a riot.

Canadian law is based on the common-law concepts but departs from them in several important respects. An assembly of three or more persons is unlawful not if it has an unlawful purpose but if it causes persons in the vicinity to fear that the assembly will disturb the peace tumultuously or cause others to do so. A riot is an unlawful assembly which has begun to disturb the peace tumultuously. There is no statutory offense of rout. Provision is made for reading a proclamation directing the rioters to disperse and severe penalties are provided for interfering with its reading or failing to obey its injunction to disperse.

All legal systems make some provision for dealing with conduct analogous to that covered by the Anglo-American law of riot but the formal definitions vary, as the following examples will illustrate.

Under German law, there are two separately defined offenses which are analogous to the Anglo-American concept of riot. Riot itself (*Aufruhr*) is an offense against public authority. It consists of taking part in a public riotous gathering in the course of which an official engaged in the exercise of his duties is resisted or assaulted, or in the course of which an official is subjected to force or threats to compel the commission or omission of an official act. The penalty is aggravated if the accused actually performed one of the enumerated overt acts or was a ringleader (*Rädelsführer*). Breach of the public peace (*Landfriedensbruch*) consists of several persons publicly banding together and committing jointly an act or acts of violence against persons or property. Aggravated penalties are provided, as in the case of *Aufruhr,* for ringleaders and those who have committed overt acts. In general, the penalties for *Aufruhr* are more severe than those for *Landfriedensbruch.*

French law does not separately define riot but treats it as a special case of resistance to public authority under the general heading of *rebellion,* the punishment for which varies in seriousness depending upon the number of persons involved and whether or not they are armed. The breach of peace aspect of the offense, which is central to the Anglo-American concept of riot, is not treated as a group offense in French law. (H. L. Pr.)

RIOUW ARCHIPELAGO AND DISTRICT forms part of Riouw (Riau) Province, Indon., and consists of more than a thousand islands between the Straits of Singapore to the north, the Berhala Straits to the south, and Borneo to the east. The population in 1961 was 278,966. The district comprises the Riouw (Indonesian, Riau) archipelago proper, consisting of the Great Karimun, Batam, and Bintan groups, the Lingga and Singkep islands, and, in the South China Sea, the Tambelan, Anambas, and Natuna islands. The administrative centre is Tandjungpinang (pop. [1957 est.] 54,629). The islands vary in height and size from rocky crags and small coral reefs to Bintan (sometimes called Riouw) and the main Natuna Island, each over 400 sq.mi. in area. Lingga and Singkep are almost as large; the former attains a height of 3,500 ft. and has the largest alluvial plain of the archipelago. Coral reefs and currents make navigation difficult.

The islands, scattered across main trade routes, were formerly pirate haunts. When the Portuguese took Malacca (1511), the expelled Malay ruler retained Johore on the peninsula and the islands at its southern tip. The sultans later allied themselves with the Dutch against the Portuguese. Their residence alternated between Johore and the Riouw archipelago, but after 1795 they resided in Lingga (Daik). The Dutch protested against Sir Thomas Stamford Raffles' occupation of Singapore (1819) because they considered it as part of the Riouw islands under their suzerainty.

The people are Malay, Bugi, Chinese, and small groups of aboriginals known as Benua and Orang Laut. The Malays and Bugi live by simple agriculture and fishing, with rubber and copra as cash crops. The Chinese grow pepper and gambier also, exploit the forests for timber, firewood, and charcoal (exported to Singapore), and work in the tin mines of Singkep and the bauxite mines on Bintan. (J. O. M. B.)

RIPON, FREDERICK JOHN ROBINSON, 1st Earl of (1782–1859), better known as Viscount Goderich, British statesman, prime minister from August 1827 to January 1828, was born in London on Nov. 1, 1782, the second son of Thomas Robinson, 2nd Baron Grantham. Educated at Harrow and Cambridge, he was private secretary (1804–06) to his kinsman, Philip Yorke, 3rd earl of Hardwicke, lord lieutenant of Ireland; undersecretary for war and the colonies (1809); a lord of the admiralty (1810–12); a lord of the treasury (1812–13); joint paymaster general (1813–17); and president of the board of trade (1818–23). During these years he owed his advancement first to the Yorke family and, after 1812, to his friend Viscount Castlereagh. As chancellor of the exchequer (1823–27) he was a great improvement on his predecessor, Nicholas Vansittart (afterward Lord Bexley), though he owed much of his success to the president of the board of trade, William Huskisson, who helped him to frame his popular budgets. In George Canning's ministry (April–August 1827) he was secretary for war and the colonies, and, with the title of Viscount Goderich, leader of the House of Lords. He succeeded Canning as prime minister, but was confessedly impotent and was dismissed

in January 1828. In Earl Grey's ministry (formed November 1830) he was again secretary for war and the colonies, and later (April 1833), lord privy seal. He resigned in June 1834 and soon joined the Peelites. In Sir Robert Peel's second ministry he was president of the board of trade (September 1841–May 1843) and president of the India board (May 1843–July 1846). He was nicknamed "Prosperity Robinson" by William Cobbett for his unwarranted optimism on the eve of the 1825 economic crisis; it was also Cobbett who, scornful of his record as colonial secretary, called him "Goody Goderich." Created earl of Ripon in April 1833, he died at Putney on Jan. 28, 1859.

See L. Wolf, *Life of the First Marquess of Ripon*, 2 vol. (1921); É. Halévy, *A History of the English People in the Nineteenth Century*, trans. by E. I. Watkin, vol. ii, 2nd ed. (1949). (A. AL.)

RIPON, GEORGE FREDERICK SAMUEL ROBINSON, 1ST MARQUESS OF (1827–1909), British statesman, who during a career covering more than 50 years occupied many important cabinet posts and served as viceroy of India. Only son of the 1st earl of Ripon, he was born in London on Oct. 24, 1827. Under his courtesy title of Viscount Goderich he was returned to the House of Commons in 1852 as a Liberal. In January 1859 he succeeded to his father's title, and in November of the same year to that of his uncle, Earl de Grey. A few months after entering the upper house he was appointed undersecretary for war; in February 1861 undersecretary for India; and in April 1863 secretary for war, with a seat in the cabinet. In 1866 he was appointed secretary of state for India. On the formation of the Gladstone administration in December 1868, he became lord president of the council, and in 1871 chairman of the Joint High Commission on the "Alabama" claims, which arranged the Treaty of Washington. He was elevated to a marquessate in 1871. In 1874 he became a convert to Roman Catholicism.

On the return of Gladstone to power in 1880 Lord Ripon was appointed viceroy of India, the appointment exciting a storm of controversy, as the marquess was the first Roman Catholic to hold the viceregal office. He went out to reverse the Afghan policy of Lord Lytton. Kandahar was given up and the whole of Afghanistan was secured to Abdurrahman Khan (*q.v.; see* also AFGHANISTAN: *History*). The new viceroy promoted local self-government and in certain directions curtailed the privileges of Europeans. For the controversy over the Ilbert Bill of 1883 *see* INDIA-PAKISTAN, SUBCONTINENT OF: *History*. He became very popular among Indians.

In 1886 Lord Ripon became first lord of the admiralty in the third Gladstone ministry; and on the return of the Liberals to power in 1892 he was appointed colonial secretary. He was included in Sir Henry Campbell-Bannerman's cabinet (1905) as lord privy seal and retained this office until 1908. He died at his seat, Studley Royal, near Ripon, Yorkshire, on July 9, 1909.

See S. Gopal, *The Viceroyalty of Lord Ripon* (1953).

RIPON, a cathedral city and municipal borough in the Ripon parliamentary division of the West Riding of Yorkshire, Eng., 24 mi. N.W. of York and 27 mi. N. of Leeds by road. Pop. (1961) 10,486. It lies at the foot of Wensleydale at the confluence of the Ure and its tributaries the Laver and the Skell. The Saxon village of Ripon first comes into history in the pages of Bede who describes how Abbot Eata of Melrose founded a Celtic monastery there *c.* 651. About ten years later Wilfrid founded a Benedictine monastery and became its abbot. Soon after this he was made bishop of York and became one of the leading figures in the English church. At Ripon he built a famous church, whose crypt may still be seen under the present cathedral. Wilfrid's church and monastery were both destroyed by the Danes in the 9th century, and the monastery was never rebuilt. According to a local tradition of not very ancient date, Ripon received a charter from Alfred the Great in 886. By the time of the Norman Conquest, Ripon minster was a collegiate church with secular clergy. The archbishops of York owned large properties in the neighbourhood ("the Liberty of Ripon") and had an episcopal palace which stood on the site of the present courthouse, on the north side of the cathedral. In 1132 Archbishop Thurstan gave land in Skelldale to a band of monks from St. Mary's abbey, and escorted them from Ripon to the place where the ruins of Fountains abbey stand, 3 mi. W.

The greatest attraction for the modern visitor to Ripon is its lovely cathedral. Apart from the Saxon crypt the oldest parts are the chapter house and the Norman undercroft; the architecture of the present building belongs mainly to the Norman Transitional and Perpendicular periods. The nave (without aisles), north transept and part of the choir were built by Archbishop Roger in 1154, while the side aisles were added about 1500 when the central tower and south transept were rebuilt. The central tower is of special interest because it has two round and two pointed arches, indicating that the Perpendicular work was left unfinished. The twin towers of the west front are Early English (about 1216), and the Lady loft (now the library) dates from the 14th century. The chancel contains misericords, carved by the Ripon woodcarvers between 1489 and 1494, and also some fine canopies. The cathedral library, collected since *c.* 1608, has some exceptionally rare books and manuscripts. The 12th-century Leper chapel, within a few minutes' walk of the cathedral, contains a pre-Reformation stone altar.

Ripon has a large and beautiful market square, surrounded by a variety of houses, shops and inns of different dates. One of these buildings is a 15th-century house where Hugh Ripley, the last wakeman and the first mayor of Ripon, once lived. The name of the chief official was changed from wakeman to mayor in 1604 when James I gave the town a charter of incorporation. Another building in the square is the town hall (1798) on which these words are inscribed: "Except the Lord keep the City the Wakeman waketh but in vain." The ritual of the hornblowing, dating from before the Conquest, is of great interest. Every evening at nine o'clock curfew is rung on the cathedral bells, and the horn is blown at each corner of the market place and also outside the mayor's house. Originally this was a sign that the watch had been set and the citizens could sleep in peace. The original 9th-century Saxon horn may still be seen at the town hall.

The diocese of Ripon was re-established in 1836 by the division into two parts of the ancient diocese of York. The dioceses of Wakefield and Bradford have since been carved out of Ripon, which now includes Leeds and the country north as far as the Tees. A church training college for women teachers was founded in 1863.

Outside the town of Ripon is a race course which holds several meetings a year. (A. M. W.)

RIPPLE MARKS. The alternating parallel ridges and troughs formed on the surface of sand by waves and currents of water or air are known as ripple marks. Granular materials of little cohesion are essential for the formation of ripple marks by water waves and currents; they may be made by wind on dust as well as on sand. Under some conditions ripple marks may be made on deposits of small pebbles.

Wave-formed or oscillation ripple marks have sharp, symmetrically sloped crests and rounded troughs. Current-formed ripple marks have rounded, asymmetrically sloped crests and troughs, the upcurrent slope being the longer and more gently inclined. Ripple marks are readily preserved when the sediments on which they are formed are transformed into rocks. Fossilized current ripple marks show the directions of the forming currents.

Although most water ripple marks are formed in relatively shallow water, they may be formed at any depth at which wave and currents are able to move sand. Wave ripple marks have been reported in the Indian ocean at a depth of 617 ft., and current ripple marks may form at depths exceeding 2,000 ft.

Since deposits made over wave ripple marks have corresponding crests and troughs on their undersurfaces, and since these are readily distinguishable from the originals, a valuable method of determining bottoms and tops of overturned strata is provided. Current ripple marks are not of great value in such investigations.

RISENBURGH (VANRISEMBURGH), **BERNARD VAN,** the name of three generations of Parisian furniture makers of Dutch origin.

The eldest, BERNARD (working before 1696–1738), was established in Paris before 1700 and in 1722 became a member of the cabinetmakers' guild (*maître-ébéniste; see* WOODWORK, DECORATIVE).

His eldest son, BERNARD II (working before 1730–1763 or 1766), became one of the outstanding French furniture makers of the Louis XV period. Trained in the family workshop, he was a *maître-ébéniste* before 1730, when he set up his own establishment; his furniture is stamped with the initials B.V.R.B. He worked in a highly idiosyncratic style in wood marquetry and in lacquer veneers and was probably the first craftsman to embellish furniture with Sèvres porcelain. His work may be seen in the Louvre, Paris; the Victoria and Albert Museum, London, and the Royal Collection; but much is in U.S. and French private collections.

His son, BERNARD III (fl. *c.* 1765–1775), worked in the family workshop. The workshop was closed at his widowed mother's death (*c.* 1773–75).

See J. Baroli, "Le mystérieux B.V.R.B.," *Connaissance des Arts,* pp. 57–63 (March 1957). (F. J. B. W.)

RISTIC, JOVAN (1831–1899), Serbian statesman, twice regent of Serbia and three times prime minister, was born at Kragujevac on Jan. 16 (new style), 1831. He studied in France and at Heidelberg University. In government service, he went to Istanbul as secretary of Prince Milosh Obrenovich's deputation (1860) and was elected (1861) clerk of the *Skupstina* which passed new bills tabled by the prince of Serbia, Prince Michael Obrenovich. As diplomatic representative in Istanbul (1861–67) he secured the withdrawal of the last Turkish garrisons from Serbia. He was appointed foreign minister in November 1867, but having refused to comply with Prince Michael's wishes was dismissed in December before receiving his seal of office.

After Prince Milan Obrenovich's accession (July 2, 1868), although elected second regent, he was mainly responsible for the new constitution (1869), and prevented Serbia from falling under Austrian influence. When Prince Milan attained his majority (Aug. 22, 1872) Ristic became foreign minister, then prime minister (April 5–Nov. 3, 1873). He was again twice foreign minister (1875, 1876–78). Against his will he was induced to conduct two wars against Turkey (1876, 1877–78). He represented Serbia at the Berlin congress (1878) which proclaimed Serbia's independence and increased its territory. Meanwhile having been acknowledged as the leader of the Liberal Party, Ristic formed his second government (Oct. 13, 1878–Oct. 26, 1880), resigning because of his failure to secure a trade agreement with Austria-Hungary. He presided over a coalition ministry (June 13–Dec. 31, 1887) till it broke up.

After King Milan's abdication (March 6, 1889), Ristic became head of the regency, the main duties of which were to enforce the new constitution (1888) and counteract the influence of the Radical government. This he dismissed (1892), replacing it with a Liberal government. When King Alexander Obrenovich dismissed the regents (April 1893) and declared himself of age, Ristic retired from politics. He died in Belgrade on Sept. 4 (N.S.), 1899. He published *Spoljašnji odnošaji Srbije novijega vremena* (three vol., 1887–1901) and *Diplomatska istorija Srbije za vreme Srpskih ratova za oslobodjenje i nezavisnost* (two vol., 1896–98).

See B. Petrovic, *Jovan Ristic* (1912). (K. St. P.)

RISTORI, ADELAIDE (1822–1906), Italian actress, was born at Cividale del Friuli, Jan. 29, 1822, the daughter of strolling players. She began her career as a child actress and at the age of 14 was cast in the title role of Silvio Pellico's *Francesca da Rimini.* She joined the Royal Sardinian Company as ingénue and advanced in two years to the position of leading lady. At 18 she attempted the title role in Schiller's *Maria Stuart.* In 1855 she went to Paris. The devotees of Mlle Rachel found that the foreign guest lacked the pure classicism for which the French star was famous, but there were other critics, the elder Dumas among them, who adored the passionate outbursts and spontaneity of the Italian temperament which broke through the general stateliness of Ristori's grand style. When she played the comic part of Mirandolina in Goldoni's *La Locandiera,* the approval of the Parisians was unanimous. She finally triumphed as a tragedienne in Alfieri's *Mirra.* She later appeared in Germany, Vienna, London, Warsaw, and Madrid. Her repertory included Racine's *Phèdre,* Legouvé's *Médée,* and Shakespeare's Lady Macbeth. She toured the United States for the first time in 1866, and her successes encouraged her return in 1867, 1875, and 1884. In 1874 the actress embarked upon a professional tour around the world. She retired from the stage in 1885 and three years later published her *Memoirs and Artistic Studies,* a volume containing analyses of her outstanding tragic roles. She died on Oct. 8, 1906, in Rome. (A. M. N.)

RITES AND CEREMONIES. Rites may conveniently be defined as traditional performances to which conventional symbolic meaning is attached by those who believe in them. A ritual is the prescribed order for performing a series of rites. This means that ritual acts are not explicable solely in terms of the practical effects they produce in some technological sense. If a rite is held by its practitioners to have practical effects, then these are deemed to be brought about by supernatural means. On the other hand the rationale of ritual acts, though commonly supernatural, is not invariably so. A graduation ceremony from an educational institution can, for example, be interpreted as a symbolic statement about the passage of students to a graduate status and it need not have any supernatural overtones. Note that this use of the term rite is distinct from that in ethology (*q.v.*) where it refers, *e.g.,* to the mating activities of species of fish, from which the elements of social prescription and symbolic significance are lacking. It also differs from the psychological usage where rite may refer to routines followed by obsessional neurotics, the elements of social prescription and conventional significance being similarly absent (*see* NEUROSES: *Obsessive-Compulsive Reaction*).

The analysis and classification of rituals has proved a difficult problem in social anthropology. At one time it was thought that a useful distinction could be made between magical rites and spells on the one hand and religious rites and prayers on the other. The historical development of this point of view is given in MAGIC, PRIMITIVE. A basic discussion of the significance of rites and ceremonies in all societies may be found under SOCIAL ANTHROPOLOGY: *Ritual Relations.*

RITES CONTROVERSY, a 17th–18th century argument originating in China among Roman Catholic missionaries about whether the ceremonies honouring Confucius and one's forefathers were so tainted with superstition as to be incompatible with Christian belief. The Jesuits were persuaded that they probably were not and could be tolerated within certain limits; the Dominicans and Franciscans took the opposite view and carried the issue to Rome. In 1645 the Congregation for the Propagation of the Faith, on the basis of a brief submitted by the Dominican Juan Bautista de Morales, condemned the rites. But after considering the arguments of the Jesuit Martino Martini, the same congregation in 1656 lifted the ban.

The continuing dispute involved leading universities in Europe, solicited the attention of eight popes and of the K'ang-hsi emperor, led to repeated intervention by the Congregation for the Propagation of the Faith and by the Holy Office, and occasioned two papal legations to China. By the end of the 17th century many Dominicans and Franciscans had come to share the Jesuits' opinion, but the tide in Rome was against them. In a decree of 1704, reinforced in 1715 by the bull *Ex illa die,* Clement XI banned the rites. Benedict XIV in 1742 reaffirmed the prohibition and forbade further debate.

Almost two centuries later the Holy See reexamined the question. A decree of Dec. 8, 1939, authorized Christians to take part in ceremonies honouring Confucius and to observe the ancestral rites.

RITSCHL, ALBRECHT (1822–1889), German theologian whose views influenced a generation of Protestant historians, was born in Berlin on March 25, 1822, the son of an evangelical church superintendent and bishop of Pomerania. He studied at Bonn, Halle, Heidelberg, and Tübingen, and taught theology at the universities of Bonn, 1846–64, and Göttingen, from 1864 until his death on March 20, 1889. Among his principal works are: *Die christliche Lehre von der Rechtfertigung und Versöhnung* (three volumes, 1870–74; 3rd edition 1888–89; English translation of volume i, 1872; of volume iii, 1900); *Die Geschichte des Pietismus* (three volumes, 1880–86); *Unterricht in der christlichen Religion* (1875; 3rd edition 1886); *Theologie und Metaphysik* (1881; 2nd edition 1887).

Ritschl's youthful biblical conservatism was shaken by the Hegelianism of the Tübingen theologian Ferdinand Christian Baur (*q.v.*). In his earliest writings he agreed with Baur that Christianity is a historical development of perfectly logical pattern rather than a dogma once and for all revealed. By the time of the second edition of his work on the origin of the old catholic church (*Die Entstehung der altkatholischen Kirche*, 1857), he had abandoned this position completely. Henceforth he refused to force the results of historical research into preconceived speculative patterns. He thought that the New Testament history of Jesus Christ, viewed simply as history and not as miracle, can lead to a practical rather than speculative judgment affirming Jesus' divine mission. Ritschl's was a theology of revelation based on this unity of history and practical-moral or faith judgment. Heavily dependent on Kant, Ritschl understood religion as the triumph of the spirit (or moral agent) over man's natural origins and surroundings. He rejected for use in theology what he understood to be the impersonal generalizations of metaphysics and the natural sciences. The mystical or intuitive elements of the religious life were also completely foreign to his activist outlook: the goal of Christian life, he maintained, is work in and for the Kingdom of God. With Friedrich Schleiermacher (*q.v.*), from whose sensitive, aesthetic mode of thought he otherwise diverged, Ritschl shared the belief that for Christianity God is not known as self-existent; he is known only insofar as he conditions human trust in his self-revelation through Christ.

Ritschl's theology was representative of an era that had little feeling for the element of mystery in religion and no dread of a divine judgment. His effort to maintain a theology of revelation but to do so without the faith in miracles underlying the older dogma was bitterly attacked by both liberal and conservative critics. He claimed for theology the status of a properly self-contained and specialized technical discipline among many other such disciplines. For this and other reasons he failed to do justice to the subtle interweaving of Christianity with general human history and culture. His followers included such diverse figures as Julius Kaftan, Wilhelm Herrmann, Ferdinand Kattenbusch, Friedrich Loofs, and Adolf von Harnack.

RITSCHL, FRIEDRICH WILHELM (1806–1876), German classical scholar, known for his work on Plautus and as the founder of the "Bonn" school of classical scholarship (*q.v.*), was born at Grossvargula, near Erfurt, on April 6, 1806. After studying at Leipzig and Halle, he held professorships at Halle (1832–33) and Breslau (1833–39). As professor of Latin at Bonn (1839–65) he attracted many talented students and gave a new impulse to Latin studies in Germany. He left after an academic quarrel with his colleague, Otto Jahn, and spent the rest of his life as professor at Leipzig, where he died on Nov. 9, 1876.

Though active in Greek studies, Ritschl was primarily a Latin scholar. Inspired by the textual criticism of Richard Bentley and Gottfried Hermann, he early determined to lay the scholarly foundation for a new understanding of archaic Latin. He aimed at a new critical edition, based on new manuscript evidence, of the largest surviving body of early Latin literature, Plautus' comedies. Ritschl edited nine plays of Plautus (4 vol. 1848–54, 2nd ed. 1872–1902; with important prolegomena), and then returned to the task more congenial to him: the study of the preliminary problems that impede the progress of an editor of Plautus. The complete text of Plautus (4 vol. 1871–94) contained only one play, the *Trinummus*, prepared by Ritschl for the final edition, the rest being edited or re-edited by his pupils and collaborators. His contribution to classical studies, therefore, lies chiefly in his numerous papers on early Latin grammar and metre, and on the manuscript tradition of Plautus, collected with other studies, in his *Opuscula philologica* (5 vol. 1867–79). Ritschl was also one of the founders of modern epigraphy: with T. Mommsen he published *Priscae Latinitatis monumenta epigraphica* (1862), an edition of the earliest Latin inscriptions.

RITTENHOUSE, DAVID (1732–1796), U.S. astronomer, who introduced in 1786 the use of spider lines in the focus of a transit instrument. He was born at Germantown, Pa., on April 8, 1732. First a watchmaker and mechanician, he afterward was treasurer of Pennsylvania (1777–89), and from 1792 to 1795 director of the U.S. mint (Philadelphia).

He was a fellow of the Royal Society of London, and a member, and in 1791 president, of the American Philosophical Society. His researches were published in the *Transactions of the American Philosophical Society* (1785–99). He died at Philadelphia on June 26, 1796.

RITTER, CARL (1779–1859), German geographer and, with Alexander von Humboldt, the joint founder of modern geographical science, was born at Quedlinburg on Aug. 7, 1779. As a boy at the famous school of Schnepfenthal he came under important teachers such as Christian Salzmann and Johann Guts Muths and was later influenced by J. H. Pestalozzi (*q.v.*). After two years at Halle University Ritter was from 1798 to 1815 tutor to the family of the bankers Bethmann Hollweg at Frankfurt am Main, traveling with his pupils in Germany, Switzerland, and Italy and visiting the universities of Geneva and Göttingen.

Pestalozzi's educational principles and the ideas of J. G. Herder (*q.v.*) on the relations between mankind and its environment led Ritter to geographical teaching and philosophy. He regarded natural history, human history, and geography as an inseparable complex and laid the foundations of human geography.

At Göttingen he wrote *Die Erdkunde im Verhältnis zur Natur und zur Geschichte des Menschen* (two volumes, 1817–18). In 1819 he taught history and geography at a Frankfurt high school, becoming in 1820 professor of geography at the University of Berlin, where he remained till his death. The second edition of his *Erdkunde* (1822–58) was on a larger scale, but it covered only Africa and Asia. His work is a regional geography and cultural history. In contrast to the geographical compendiums of the 18th century, and also to the so-called pure geography which sought to exclude political boundaries and human activities, Ritter's new concept paid regard to natural regions and the influence of human history in them. The earth was for Ritter an organism, its continents and countries individual units linked by the functional relations of their elements. In his devout Protestantism he saw his scientific activity as in the creator's service and the earth as a divine establishment for man's education. His teleology, later much criticized, was an amalgam of his pedagogic, historical, and geographical thought. Ritter died in Berlin on Sept. 28, 1859, a few months after Humboldt.

RITUALE ROMANUM, or the "Roman Ritual," traditionally one of the seven official books of the Roman rite, provides, along with the missal (*q.v.*) and breviary (*q.v.*), texts and directions for all the functions a priest performs.

Its contents are grouped under 12 "titles": (1) administration of the sacraments in general; (2) baptism; (3) confirmation; (4) penance; (5) the Eucharist; (6) care of the sick; (7) funerals; (8) weddings; (9) blessings, reserved and nonreserved; (10) processions; (11) litanies; (12) exorcisms. There is also an appendix with hymns, blessings, and instructions and, at least in some printings, a supplement with adaptations to the vernacular of the locale.

The first *Rituale romanum* was published under Pope Paul V in 1614, although its use was not enjoined with the rigour with which the official *Pontificale romanum* (*see* PONTIFICAL) had been imposed by Clement VIII in 1596. The medieval predecessors of the *Rituale romanum* were the sacramentaries (*see* SACRAMENTARY) and a large collection of manuals called by such names as *Obsequiale, Ordinarium, Liber benedictionum, Liber agendorum, Agenda, Manuale, Benedictionale, Pastorale, Sacerdotale, Rituale, Alphabeta sacerdotis.* Revisions of the *Rituale romanum* were published by Pius XI in 1925 and by Pius XII in 1952. Prior to the second Vatican Council, certain territories had their own variations of the *Rituale romanum, e.g.*, in the form of an appendage to it approved by the Holy See. One of the points of such variations was the integration of the local language, to a greater or less degree, into the liturgy. Since the second Vatican Council the use of languages other than Latin has been greatly broadened. U.S. usage is now determined by the *Collectio rituum* (1964), published by the authority of the National Conference of Bishops of the United States.

See *Rituale romanum Pauli V pont. Max. jussu editum aliorumque pontt. cura recognitum atque ad normam codicis juris canonici accommodatum, ssmi. d. n. Pii XII auctoritate ordinatum et auctum* (1952). (EA. A. W.)

RITUAL MURDER: *see* HUMAN SACRIFICE.

RIVADAVIA, BERNARDINO (1780–1845), first president of the Argentine republic, was born at Buenos Aires on May 20, 1780. His education at the College of San Carlos was interrupted by the British invasion of 1806. In 1811 he became secretary to the revolutionary triumvirate and later was made a member of that body. To secure the recognition of an independent United Provinces of La Plata, and a Spanish prince to rule it, he was sent with two other diplomats to Europe and was partly responsible for the British acceptance of the United Provinces into the family of nations. Upon his return to Buenos Aires he was appointed, under Gov. Martín Rodríguez, one of the two ministers of government (state) and used his office to introduce reforms in the civil government and courts and to found hospitals, asylums, and schools, including the University of Buenos Aires.

Politically, he was a Unitarist, or nationalist, and in time became the party leader in opposition to the Federalists. He favoured the establishment of a monarchy with Spanish leanings. In 1826 he was elected president of the United Provinces of La Plata, which, a few months later, adopted a constitution for the Argentine republic.

From the outset the presidency proved to be an unhappy office. Not only was Argentina bitterly divided over the question of federalism versus nationalism, but it was also involved in war against Brazil concerning the independence of Uruguay, then known as Banda Oriental. Handicapped by the internal dissension, Rivadavia accepted the offer of British mediation and a treaty of peace was drafted which recognized Brazilian hegemony of the disputed area. The people of Argentina refused to accept that arrangement, however, and Rivadavia was forced to continue the war.

When the provinces declined acceptance of the proposed constitution, Rivadavia resigned his office (1827). In 1834 his political enemies brought charges against him in the courts, and without having been given a hearing he was sentenced to exile within 24 hours.

He went first to Brazil, then to Cádiz, Spain, where he died on Sept. 2, 1845. His remains were repatriated in 1857 and 23 years later his birthday was decreed a national holiday.

BIBLIOGRAPHY.—There is a wealth of material in Spanish concerning Rivadavia, among which may be noted C. Correa Luna, *Rivadavia y la simulación monárquica de 1815* (1929); A. Lamas, *Rivadavia; su obra política y cultural* (1915). In English *see* Ricardo Levene, *A History of Argentina*, trans. by W. S. Robertson (1937). (R. G. RR.)

RIVAROL (ANTOINE RIVAROLI), called COMTE DE (1753–1801), French writer remembered mainly for the pithy, sparkling wit of the maxims and comments of his *Carnets* and his brilliant essay, *Discours sur l'universalité de la langue française* (1784). Born at Bagnols (Gard) on June 26, 1753, he was educated by and for the church, but forsook his ecclesiastical career and in 1777 reached Paris, where his erudition, wit, and talents as a conversationalist made him welcome in polite society. Though a freethinker and critical of Louis XVI, he remained faithful to the monarchy, campaigning against the Revolution in the Royalist press and in his *Petit dictionnaire des grands hommes de la Révolution* (1790). Prudently, he emigrated in 1792, living successively in Brussels, London, Hamburg, and Berlin, where he died on April 11, 1801.

Rivarol's political writings anticipate French 19th-century traditionalism and defend the social order whose tastes he reflected in his literary work. A dispassionate, acute observer, Rivarol caustically satirized contemporary writers, more especially in his *Petit almanach de nos grands hommes* (1788).

See *Oeuvres*, ed. by M. de Lescure, 2 vol. (1880); A. Le Breton, *Rivarol* (1895).

RIVAS, ÁNGEL DE SAAVEDRA, DUQUE DE (1791–1865), Spanish poet, dramatist, and politician, whose fame rests principally on his play *Don Álvaro* which marked the triumph of Romantic drama in Spain. Born in Córdoba, March 10, 1791, he was educated at the *Seminario de Nobles* in Madrid and later fought gallantly in the War of Independence. Retiring afterward to Seville he published a first book of verse, *Poesías* (1814), which reveals the influence of Juan Meléndez Valdés and Manuel José Quintana, and a number of tragedies on the French classical model (*Ataulfo*, 1814; *Lanuza*, 1822). After entering politics he was condemned to death in 1823 for his extreme liberal views. He fled to London and lived subsequently in Italy, Malta, and France, where he earned his living by painting. During his exile he came under that Romantic influence which, already visible in *El moro expósito* (1834), was to triumph in his *Romances históricos* (1841).

Returning to Spain after the amnesty of 1833, he presently inherited the title of duque de Rivas and on March 22, 1835, staged *Don Álvaro*, whose place in the history of the Spanish theatre is analogous to that of Victor Hugo's *Hernani* in France. His later dramas are undistinguished. In 1836 he became minister of the interior under Francisco de Istúriz and in the following year was again compelled to flee owing to his conversion to conservative opinions. Returning in 1838 he entered the senate and was subsequently ambassador in Naples and Paris. He died, while president of the Spanish Academy, on June 22, 1865. (D. L. SH.)

RIVAS, a small department in southwestern Nicaragua, lying between the Pacific Ocean and Lake Nicaragua; also the departmental capital. Area of the department 830 sq.mi. (2,150 sq.km.). Pop. (1963) department 64,361; city 7,721.

Most of the people are concentrated in valleys in the central part of the department. This area is important for livestock raising and the production of cacao, corn, beans, rice, and tobacco. The Inter-American Highway crosses the department from north to south, and branch roads connect the town of Rivas with San Jorge, a port on Lake Nicaragua, and San Juan del Sur, the second-ranking Nicaraguan port on the Pacific and a popular seaside resort. (C. F. J.)

RIVER, any natural stream of fresh water, larger than a brook or creek, which flows in a well-defined channel. Usually it dis-

charges into an ocean, a lake, or another river. In rare instances in regions of porous soil it soaks into the ground, or, in excessively arid regions, evaporates, in which case it becomes a "lost river." In regions of favourable rock conditions it may also run underground for certain distances, disappearing and reappearing, perhaps more than once. A river with a well-cut channel and a graded bed, usually reaching base level at its mouth, is an adolescent river. Rivers as they grow older usually widen their valleys accordingly unless prevented by certain geological formations or occurrences. A river whose upper waters sometime in the past suddenly found a new outlet, diminishing the volume and force of the original river and also its length, is known as a beheaded river. (For other facts relating to the origin and subsequent development of rivers and their valleys *see* GEOLOGY: *Physical Geology: Geomorphology.*)

This article will discuss principally those physical characteristics of rivers that can be, under proper control and management, useful to man and the necessary engineering techniques required for such control. Some of the more important of these are described in this article as follows:

I. Physical Characteristics of Rivers
  1. River Basins
  2. Available Rainfall, Snowfall, and Snow Melting
  3. Slope of Rivers
  4. Discharge Variations
  5. Materials Carried by Currents
  6. River Channels
  7. Floods
II. Mitigation of Floods and Protection from Inundations
  1. Discharge Efficiency
  2. Prediction of Floods
  3. Embankments
  4. Local Protection Projects
III. Improvement of Nontidal Rivers for Navigation
  1. Removal of Shoals
  2. Dikes and Dams
  3. Refuge Ports
IV. Clearance of Small River Outlets
V. Improvement of Deltaic Outlets of Tideless Rivers
  1. Parallel Jetties
  2. The Delta of the Danube
  3. The Mississippi Delta
VI. Improvement of Tidal Rivers for Navigation
  1. Tidal Flow
  2. Dredging
  3. Regulation Works
  4. Effect of River Deepening on Tidal Levels
  5. Estuary Training Works
  6. Gravity Flow

Other river engineering works are dealt with under separate headings, for instance, the utilization of river waters for power production (*see* ELECTRIC POWER); works for water storage and supply for various purposes including irrigation (*q.v.*); works connected with fisheries (*q.v.*); for erosion control and reclamation of land (*see* BREAKWATER; LAND RECLAMATION). *See* also the articles on DAM; MECHANICS, FLUID; RESERVOIR; WATER TRANSPORT, INLAND; WEIR; and particular rivers; *e.g.,* MISSISSIPPI RIVER; DANUBE.

I. PHYSICAL CHARACTERISTICS OF RIVERS

1. River Basins.—In general the size of rivers above any tidal limit and their average freshwater discharge depend upon the extent of their basins and the amount of rain over those basins. These vary, according to the configuration of the country, from the insignificant drainage areas of streams falling from high ground near the coast and flowing straight down to the sea to the immense parts of continents, where rivers, after flowing down the slopes of mountain ranges, traverse vast stretches of valleys and plains before reaching the ocean. The comparative size of some of the principal river systems of the world is shown in the table.

River and location	Drainage basin in square miles	Length in miles
Nile, Africa	1,100,000	4,157
Amazon, South America	2,722,000	3,915
Missouri-Mississippi, U.S.	1,243,700	3,860
Ob–Irtysk, U.S.S.R.	1,131,000	3,461
Yangtze, China	756,498	3,434
Yellow, China	486,486	2,901
Rio de la Plata (system), South America	1,680,000	2,796
Congo, Africa	1,425,000	2,716
Lena, U.S.S.R.	936,293	2,653
Mackenzie, Canada	682,000	2,635
Niger, Africa	580,000	2,600
Amur-Kerulen, U.S.S.R.	758,000	2,552
Yenisei, U.S.S.R.	1,003,474	2,566
Volga, U.S.S.R.	533,818	2,293
St. Lawrence, Canada/U.S.	291,900	1,900
Brahmaputra, Asia	361,000	1,800
Indus, Asia	372,000	1,800
Danube, Europe	315,444	1,777
Zambezi, Africa	513,500	1,700
Murray, Australia	414,253	1,609
Orinoco, South America	350,000	1,281

2. Available Rainfall, Snowfall, and Snow Melting.—All these factors vary considerably in different localities, both in their total yearly amount and in their distribution throughout the year; also their volumes fluctuate from year to year.

Even in small river basins the variations may be considerable according to differences in elevation or distance from the sea. For instance, in the Severn Basin in England and Wales, with an area of only 4,350 sq.mi., the rainfall varies from an average of less than 30 to more than 80 in. per year. The proportion, moreover, of the rain falling on a river basin which actually reaches the river, *i.e.,* the available rainfall in respect to its flow, depends very largely on the nature of the surface strata, the slope of the ground, and the extent to which it is covered with vegetation. The available rainfall has been found to vary from 75% of the actual rainfall on impermeable, bare, sloping, rocky strata down to about 15% on flat, permeable soils.

3. Slope of Rivers.—The rate of flow of rivers depends mainly upon their slope and the roughness of their channel, though where two rivers of different sizes but the same roughness have the same slope, the larger river has the quicker flow, as its retardation by friction against its bed and banks is less in proportion to its volume than that of the smaller river. The fall of a river corresponds approximately to the fall of the country it traverses, but its slope is generally more gentle because of its meandering alignment. Near the source, frequently in hilly regions, the slope of rivers is usually steep, but it gradually flattens out, with occasional irregularities, until, in traversing plains along the latter part of their course, the slope usually becomes quite gentle. Accordingly, in large basins, most rivers begin as torrents with a very variable flow and end as gently flowing rivers with a comparatively regular discharge.

4. Discharge Variations.—In tropical countries subject to periodic rains, the rivers are in flood during the rainy season. Where the annual flood depends to a large extent on melting snows, the rivers are in their high stages in late spring and early summer. In snowless countries sudden and largely unpredictable floods occur frequently in winter when the rate of evaporation is relatively low and the ratio of runoff to rainfall is therefore high. Occasionally heavy rainfall may then be the cause of a sudden rise of the river level, resulting in much damage—unless duly provided for by the engineer. Mixed conditions are characteristic of rivers fed partly by snow and partly by rain. During the mid-20th century, scientists strove to develop a reliable method of predicting river discharges solely from meteorological data. Successful results were reported on studies of the Dnieper in the U.S.S.R., and valuable research was carried out in both England and the U.S. The more successful methods of river-flow prediction still entailed a knowledge of antecedent discharges and soil moisture.

5. Materials Carried by Currents.—In floodtime rivers bring down a large quantity of detritus, derived mainly from the disintegration of the surface layers of the hills and slopes in the upper parts of the valleys by glaciers, frost, and rain. The power of a current to transport materials depends to a large extent on its velocity, so that torrents with a rapid fall near the sources of rivers can carry down rocks, boulders, and large stones. These are ground by attrition in their onward course into shingle, gravel, sand, and silt, and are carried forward by the main river toward the sea or partially strewn over flat alluvial plains during floods. The size of the materials forming the bed of the river or borne along by the stream becomes less as the reduction of velocity diminishes the transporting power of the current.

Since the earliest days of modern hydraulics (17th century, in

Italy), progressive engineering research has attempted to solve the problem of sediment transportation. Because sediment particles are generally heavier than the amount of water they displace, the Archimedean flotation law could not be used to explain the fact that heavy sediment was capable of being lifted and transported by flowing water. Another explanation was, consequently, required. The solution of this problem would also provide information on the measures to be taken to control soil erosion and silt deposits in the channels of rivers.

Modern research distinguishes between "bed load" on the one hand and "suspended sediment" on the other. The former is composed of the larger particles which are either rolled or pushed along the bed of the river or "jump" (*i.e.*, saltate) from the crest of one ripple to another if the velocity is sufficiently great. On the other hand the smaller particles, *i.e.*, the suspended sediment, once picked up and lifted by the moving water, may remain in suspension for considerable periods of time and thus may be transported over many miles. Bed load is capable of an easier explanation than suspended sediment because with the former the velocity of the moving particles is less than that of the water, whereas with the latter both velocities are equal. In one case, therefore, there is an impact effect due to the difference of velocities, while in the other such effect is absent.

Various theories suggested to explain the phenomenon of sediment suspension include the following: (1) the belief of J. Dupuit and A. Flament that a rigid body transported by the flowing water tends always toward the region of maximum velocities, and, as the surface velocity is usually greater than the bed velocity, that a sediment particle, picked up from the bed, must of necessity rise toward the surface; (2) the conclusion of N. de Leliavsky from numerous observations of velocities in rivers that the scour of a granular river channel and the lifting of its particles is due to convergent currents possessing a surplus of energy, while divergent currents have the opposite effect; *i.e.*, they cause suspended sediment to be dropped; (3) a third school of thought, which attributes the lifting of particles to the rising components of the crosscurrents. This school is subdivided into two groups: those who believe the crosscurrents form part of a pulsating but generally orderly flow pattern, and those who believe the crosscurrents to be a numberless multitude of instantaneous and disorderly agitations characteristic of an essentially turbulent flow.

6. River Channels.—A river channel eroded by the current depends obviously on the flow pattern, and the flow pattern is, in turn, affected by the form of the channel. It may therefore appear that the problem of the river channel contains the elements of a vicious circle.

A broader approach postulates that a process of mutual interaction exists between two mediums, water and granular soil, and that the channel formation due to such an interaction is controlled by certain general laws.

Among the authors who contributed to the discovery of these laws are L. Fargue, N. de Leliavsky, R. Jasmund, G. Lacey, and E. W. Lane. One of the main laws is that the natural shape of a river channel eroded in an alluvial plain does not follow a straight line but shows a tendency to meander, and, even if it were made straight through artificial means, it would soon begin to serpentine again. In fact, Fargue showed that water depth in a river is correlated with curvature of its channel in such a manner that as the curvature increases, so does the depth.

This law and others belonging to the same theory of river channels seem borne out by modern experimental evidence. The experiments of J. F. Friedkin, of the Vicksburg experiment station of the U.S. Army, as reported in *A Laboratory Study of the Meandering of Alluvial Rivers* (Vicksburg, 1945), show that "meandering is essentially a natural trading process of sediments from banks to bars . . . Under ideal conditions of uniformity, an initial bend is perfectly transmitted downstream, thus resulting in a series of uniform bends . . . . The natural process might be likened to the oscillatory course taken by a ball which has been started down a grooved incline so that it oscillates from side to side . . . ."

The more uniform the configuration of the earth surface, the nearer the river channel approaches the described ideal shape. Mountains and various other natural and man-made obstructions interfere with the formation of a natural river channel, causing local deviations from its ideal sinusoidal shape.

7. Floods.—River floods may be either annual or sporadic. An outstanding example of an annual flood is that of the Nile, always occurring during the months of August and September and fed by the monsoon rains falling over the equatorial districts of central Africa. The floods of the Seine at Paris are typically sporadic, for though they usually occur in winter, their dates and intensities are subject to much variation. Such floods are caused by rain falling on melting snow and by a heavy rainfall on land already sodden by recent rains at a period of the year when evaporation is inactive. A fairly simultaneous rainfall over the greater part of a moderate-sized river basin is a fairly common occurrence; under such conditions the floods coming from the torrential tributaries reach their maximum height and begin to subside before the floods from the gently flowing tributaries attain their greatest rise.

II. MITIGATION OF FLOODS AND PROTECTION FROM INUNDATIONS

As the size of a river channel is generally inadequate to carry down the discharge of floods, the river overflows its banks in floodtime and inundates adjacent low-lying lands. An enlargement of a large riverbed, principally by deepening it, in order to increase its discharging capacity, is precluded by the cost and in some cases by the large deposit of sediment that would take place in the enlarged channel from the reduction in the velocity of the current when the flood begins to subside. Where, however, the depth of a smaller river has been considerably increased by dredging, the enlargement of its channel and the lowering of its low-water line facilitate the passage of the land water and consequently reduce the danger of flooding.

It is possible to restrict or prevent the inundation of some river areas by embankments, but occasionally low-lying lands are so unfavourably situated that pumping is necessary. The flow of water off mountain slopes can be retarded by planting trees on the slopes.

However, the most efficacious way of mitigating floods is to reduce the peak of the flood by withdrawing some part of the natural discharge from the river. This may be done either by diverting the flow in a low-lying depression or by building a dam across the valley of the river and storing behind it a part of the flood discharge. An example of diversion is the scheme of works on the Tigris and Euphrates rivers, in Iraq, part of which was completed in the early spring of 1956. The floods of these rivers have always been a major problem and have caused much damage to the town of Baghdad and the surrounding cultivated area. The Ramadi barrage and Warrar regulator were built to divert part of the flood of the Euphrates into Lake Habbaniyah, some of the water to be returned into the river during the drought season through the Dhibba outlet. In more or less the same manner, the Samarra barrage and inlet regulator were designed to divert the flood of the Tigris into the Tartar depression, through a 65-kilometre (km.) inlet canal. On the other hand, the Aswan Dam on the Nile furnishes an example of a storage reservoir in the trough of the river, which may also be used for occasional flood control. The fact that floodwater is heavily laden with silt prevents this operation being carried out systematically every year, as the silt would then fill the reservoir. In the United States the flood control project in the lower Mississippi Valley included five reservoirs, all completed by the mid-1950s.

1. Discharge Efficiency.—The discharging efficiency of a river within the limits of its bed depends on the fall and the cross section of the channel. The only way of increasing the fall is to reduce the length of the channel by substituting shorter cuts for a winding course. In the case of a large river, however, it is very difficult to maintain a straight cut because the current tends to erode the banks and form again a sinuous channel. Cuts therefore should be in the form of one or more flat curves. Nevertheless, where the available fall is exceptionally small, as in lands originally reclaimed from the sea, for example the English fen

districts, straight channels have been formed for the rivers and "drains."

2. Prediction of Floods.—This term may be interpreted in two different ways. It may refer to a definite flood, the levels and dates of which must be known beforehand in order to protect the riparian population, or it may designate the probabilities of the flood magnitudes and flood frequencies of a river, which are of fundamental importance in many design problems of flood control.

The only generally accepted solution of the first problem is the use of gauges for recording water levels in the upper stretches of the river and in all its tributaries. In order to understand how these gauges can be used for predicting the levels for its lower course, a flood can be compared to a wave (see *abc* in fig. 1) that moves slowly downstream. The velocity of propagation of this solitary wave is not necessarily the same as that of the water in the river, but it is frequently of the same order of magnitude. The slope of the water surface in the downstream part of the wave, *i.e.*, in *bc*, is of necessity much steeper than in *ab*. Since the velocity of water in a river depends largely on the corresponding slope of the water surface, it follows that in *ab* the velocity is less than in *bc*. In other words, there is less water fed into the wave on its upstream side than escapes toward its downstream end, the result being that as the flood moves slowly downstream, it gradually flattens. Thus, as it reaches the position *efg*, it is

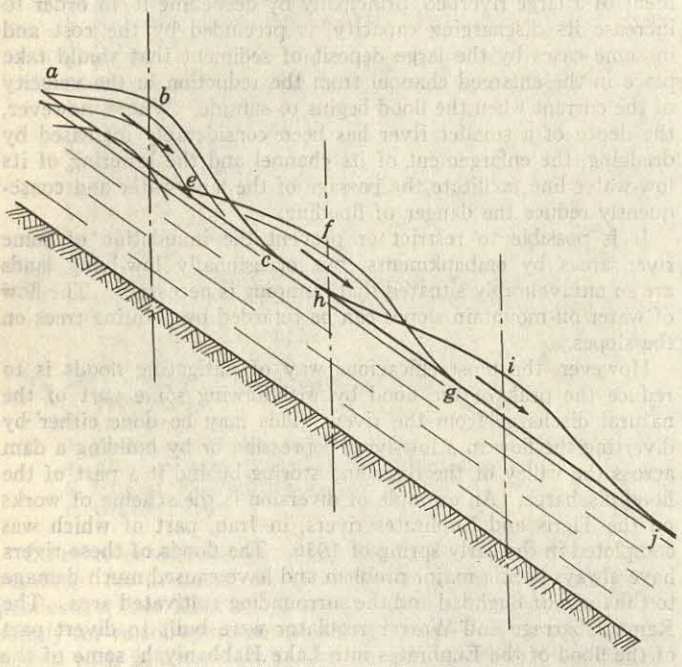

FIG. 1.—THE MOVEMENT OF A FLOOD SHOWN AS A WAVE

shallower than in *abc*, and in *hij* its height is still less. On the other hand, if two waves move in two confluents and reach the main channel simultaneously, a dangerous flood may occur. The speeds of the propagation of the waves, as well as their levels, can be calculated with remarkable precision, and the floods occurring in the entire basin of the river are consequently capable of being predicted with enough accuracy for practical purposes. The branch of hydraulics dealing with this problem is frequently called flood routing.

In dealing with the probability of flood levels and their incidence, various methods are used. Records of the Roda (Cairo) Nilometer, constructed in A.D. 716 to record the annual Nile flood levels and the departures from their mean, have supplied valuable data covering hundreds of years. From these and similar records, hydraulicians in the early decades of the 20th century, among them Allen Hazen in the U.S. and P. Philips in Egypt, adopted the use of various mathematical diagrams to systematize flood prediction data. Using the Gaussian frequency curve and data recorded from the Roda Nilometer, it has been possible to forecast future conditions accurately enough to develop a system of priorities for river engineering projects designed to meet various conditions. Straight-line plotting analysis led to the conclusion that flood levels of the Nile for the period 1737–1917 were higher than for 716–1451 and that as a result of the silt deposited by the river, the whole valley of the Nile rises gradually at a rate of about four inches per century.

3. Embankments.—Earthen banks protecting inhabited river valley areas against inundations during floods are among the earliest types of engineering works. For instance, in Egypt, the left bank of the Nile, extending from Aswan to the Mediterranean, a distance of more than 1,000 km., was begun in the time of the pharaohs, while the right bank was built somewhat later by Arab engineers. Since the very life of the country depended on these banks during floods, legend has it that some of the earlier rulers of Egypt ordered the engineer in charge of the maintenance of a bank to be thrown into any breach that occurred within his district. It has been suggested that the joint enterprise involved in building the long, tall banks necessary for the general safety must have been a strong incentive for the development of organized communal life and that it might have contributed to the rise of the great monarchies, such as those of Egypt, Mesopotamia, and China, where irrigation and hydraulic engineering were practised on a large scale.

Embankments have been adopted in other places also, where tracts of fertile alluvial land below flood level stretch for long distances away from the river. Thus the fens of Lincolnshire, Cambridgeshire, and Norfolk in England are protected from inundations by embankments along their rivers and drains; a great portion of the Netherlands is similarly protected, and the plains of Lombardy are shut off from the floods of the Po by embankments along each side of the river for a distance of about 265 mi.

For such towns as New Orleans on the Mississippi and Szeged on the Tisza (Theiss) in Hungary, which were established below the flood level of an adjoining river, the channel of the river should be improved to facilitate the passage of floods past the town. The town also should be enclosed within embankments raised above the highest possible flood level.

A system of levee embankments was extensively developed along the Mississippi River in its alluvial valley extending from Cape Girardeau, Mo., to the Head of Passes in the delta, a distance of 1,014 mi. by river channel. The alluvial valley has a length in latitude of 600 mi. and ranges from 20 to 80 mi. in width, with a total area of 35,500 sq.mi. It comprises the St. Francis, the Yazoo, the Tensas, the Lafourche, the Atchafalaya, and portions of the White and Arkansas basins, as well as the alluvial lands around Lake Pontchartrain (fig. 2).

These levees, begun by French settlers in Louisiana in the 18th century, were in 1735 about 3 ft. high and had been constructed from 30 mi. above New Orleans to 12 mi. below. From this beginning the system was extended until by the 1960s it included more than 3,500 mi. of levees having an average height of 24 ft. and a content of more than 1,700,000,000 cu.yd. of earth. The levees above Baton Rouge, La., are roughly parallel to the river but have a width between them of from $\frac{3}{4}$ to 15 mi., thereby greatly increasing the cross-section area of the river in times of flood. Below Baton Rouge the levees follow the bends in the river but are set back from the river bank sufficiently to prevent undercutting by the current during floods. In some parts the spacing is much greater.

The low-water discharge, measured at New Orleans, 123 mi. from the mouth of the Southwest Pass, has been as low as 49,200 cu.ft. per second; this, however, was affected by tide. The lowest discharge recorded at Red River Landing, La., was 75,000 cu.ft. per second. At Vicksburg, Miss., a discharge of 1,806,000 cu.ft. per second was recorded in 1927 (estimated 2,278,000 cu.ft. per second if flood had been confined to leveed river), as compared with the recorded minimum of 93,800 cu.ft. per second. During certain floods the levees had not been adequate to withstand the water pressure which had (before the record flood of 1927) a maximum rise at Vicksburg of 61.65 ft. above the 1940 low-water level. In 1927 the river at Vicksburg rose 3.55 ft. higher and 65.2 ft. above the low stage of 1940. The floods tend to increase

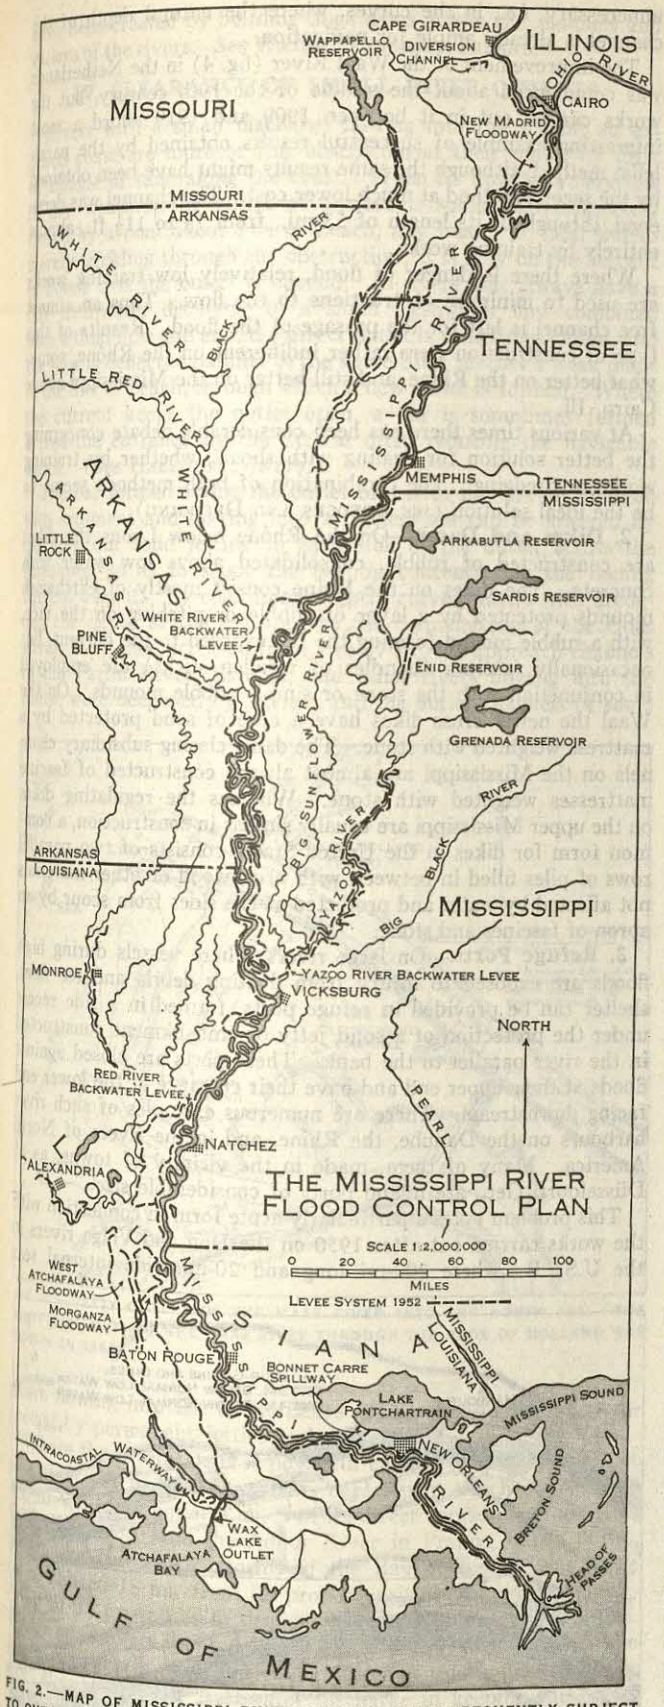

FIG. 2.—MAP OF MISSISSIPPI RIVER SHOWING AREAS FREQUENTLY SUBJECT TO OVERFLOW AND REQUIRING PROTECTIVE ENGINEERING

in height due to the confinement of the river between levees. Breaches, or crevasses, have occurred during extraordinary floods, but no crevasses occurred after 1928 in the lower Mississippi Valley. They produce a sudden rush of floodwaters through the opening which is damaging to the land in the immediate vicinity of the breach, but the general inundation is gradual and benefits the lands with a fertilizing deposit.

The great floods of the Mississippi and its tributary rivers in April–June 1927 were particularly serious. They were due to the extraordinary coincidence of flood conditions in all the chief tributaries of the river. Normally the eastern floods culminate between January and April, while the crests of the Missouri River floods usually enter the Mississippi in June. In 1927 the levees were breached in many places, and the floodwaters overflowed throughout the alluvial valley. An area of more than 23,000 sq.mi. was inundated, and 700,000 people were driven from their homes. Apprehension was averted at New Orleans by cutting a gap in the levees at Poydras, a few miles below the city, thus permitting part of the floodwaters to take a short course of about five miles to an arm of the sea instead of following the normal course of the river through the delta.

In January–February 1937, while the greatest flood of record was developing in the Ohio River, the conditions in the Mississippi River were favourable for receiving and disposing of this unprecedented discharge. The lower Mississippi was called on to carry a flood of more than 2,000,000 cu.ft. per second. The improved levee system successfully held the water within bounds, except in backwater areas of the tributaries, which were not protected.

The unprecedented flood that occurred in April–May 1965 on the upper Mississippi River resulted in extensive damage to a five-state area, extending along the course of the river for more than 1,000 mi. from Minneapolis and St. Paul, Minn., through Wisconsin, Iowa, and Illinois to a point somewhat below Hannibal, Mo. Spring rains that rapidly melted a heavy accumulation of snow and ice caused the Mississippi and Minneapolis rivers at St. Paul to discharge more than 800,000,000,000 gal. between April 12 and the 21st. The flood caused 16 deaths and left more than 40,000 people homeless, with damages exceeding $200,000,000. At Muscatine, Ia., the flood crested at 24.81 ft., 8.81 ft. above flood level, and at one point, near Burlington, Ia., the river stretched 8 mi. wide. Some levees, such as that constructed in 1963 in St. Paul, withstood the flood, but most of the dikes along the river had to be bolstered with makeshift levees, many of which could not restrain the waters.

4. Local Protection Projects.—Levees and flood walls are also utilized for protection of municipal areas. After 1930 the United States especially developed many local projects of this type, designed to provide better protection for highly developed industrial and residential areas than that provided by the continuous embankment type. A good example is that for the protection of Kansas City, Kan., and Kansas City, Mo., located at the junction of the Missouri and the Kansas rivers, which provides for a combination levee and flood wall, pumping plants, construction of a river cutoff and a highway bridge across the cutoff, and alteration of 14 bridges across the Kansas River and 2 across the Missouri River.

III. IMPROVEMENT OF NONTIDAL RIVERS FOR NAVIGATION

Because rivers form an important means of transportation, it is frequently necessary to increase the depth of the channel and thus permit larger craft to navigate the river.

Since, because of its winding alignment, a natural river channel constitutes a succession of deeps and shoals, the removal or at least the improvement of the latter is most necessary for navigation. On some rivers it is practicable to concentrate flow and fix the low-water channel by closing subsidiary low-water channels with dikes and narrowing the channel at the low stage by low-dipping cross dikes extended from the riverbanks down the slope, sometimes pointing slightly upstream so as to direct the water flowing over them into a central channel.

1. Removal of Shoals.—The traditional school of thought maintains that since the flow lines in a river are generally parallel to its banks, it suffices to constrict its channel by training works in order to cause the velocity to increase and thus wash away the sand and silt forming the shoals. The second school postulates

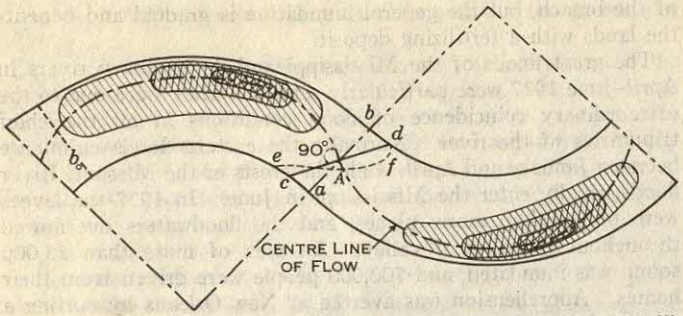

FIG. 3.—DIAGRAM OF TYPICAL MEANDER COIL, DEMONSTRATING THE INCONSISTENCY OF THE TRADITIONAL METHOD OF RIVER TRAINING BY CHANNEL CONTRACTION

that nonparallelism of the flow is itself the main cause of the formation of shoals and that neither the flow nor the shoals can be disregarded in designing training works. J. L. Van Ornum describes this second approach as "directing control of the current of the river."

A portion of a meandering river consisting of two curves with the point of inflection, *A*, at their junction, is shown in fig. 3. The general pattern of a meandering river may be visualized as a succession of such S-shaped elements, and therefore what occurs with one of them may be taken as valid for the entire river. According to Fargue's law correlating curvature and depth of channel, the depth of water within the limits of the curved parts of the river is usually ample for the requirements of navigation. But *A*, the point of inflection, constitutes a technical design problem, for the curvature of the streamlines drops here suddenly to zero, and the water depth may be expected to be, therefore, a minimum. Frequently this is found to be the case in nature, and it explains the succession of deeps and shoals; for the deeps, or pools, correspond to curves, while the shallows, or shoals, coincide with the inflection points. In this correlation between depth and curvature lies the three-dimensional principle of alluvial river channels.

Since the main objective in training a river is to permit navigation of larger, deeper-draft craft, the attention of training-works designers has been concentrated on improving channels at inflection points. This aspect of training-works design is one of several problems where parallelist and nonparallelist principles are particularly in disaccord. So long as the flow is assumed to be parallel to the banks, nature's choice of the inflection point as a locus for silting and a centre for sand deposits appears rather arbitrary. On the other hand, the reason for these deposits becomes quite clear if it is realized that at the inflection point the nonparallelism between flow and banks is particularly pronounced, for the main current crosses here from one concave bank to the other, and the area of waterways measured at right angles to the flow lines is not *ab* (*see* fig. 3), as the parallelist school would have it, but *cd* (or even the curve *ef*, according to some studies of large rivers). Since the area of waterways measured in this manner is much larger than *ab*, it follows that the velocity at the inflection point is far less than in the curve, and this explains the formation of the shoal, for as the velocity drops, the sediment carried by the current is deposited. The solution advocated by the nonparallelist school consists in dealing individually with each shoal by means of a long dike or spur protruding far into the channel of the river like a sabre in such a manner as to create a convergent, *i.e.*, scouring, type of current at the inflection point. This method is recommended to replace the traditional layout of training works, which consists of a large number of dikes and banks spread throughout the entire length of the regulated reach of the river.

While the traditional principle has frequently resulted in moderate general improvements of navigation conditions, it often caused much disappointment because new shoals developed beyond the limits of the reaches trained in this manner—or even within them. Such local troubles could then be remedied by application of the second method. The main objection, however, against the traditional method is the very large expenditure on training works located at the spots where they are altogether unnecessary, *i.e.*, in the curves, where the natural depth of the channel is already ample for navigation.

The improvement of the Waal River (fig. 4) in the Netherlands was commenced about the middle of the 19th century, but the works carried out in it between 1909 and 1919 afford a most interesting example of successful results obtained by the parallelist method, although the same results might have been obtained by the second method at much lower cost. The channel was deepened, throughout its length of 53 mi., from 7½ to 11½ ft., almost entirely by training works.

Where there is danger of flood, relatively low training works are used to minimize obstructions to the flow. Thus an almost free channel is left for the passage of the flood. Results of this type of construction were rather indifferent on the Rhône, somewhat better on the Rhine, and still better on the Mississippi above Cairo, Ill.

At various times there has been considerable debate concerning the better solution for dealing with shoals, whether by training works or dredging. The combination of both methods seems to be the ideal solution (*see* DREDGES AND DREDGING).

2. Dikes and Dams.—On the Rhône below Lyons the dikes are constructed of rubble, consolidated above low water with concrete. The dikes on the Rhine consist mostly of earthwork mounds protected by a layer of rubble or pitching on the face, with a rubble mound forming the toe exposed to the current, but occasionally fascines (bundles of wooden sticks) are employed in conjunction with the stone or simple rubble mounds. On the Waal the newer cross dikes have a core of sand protected by a mattress weighted with stone. The dams closing subsidiary channels on the Mississippi are almost always constructed of fascine mattresses weighted with stone. Whereas the regulating dikes on the upper Mississippi are usually similar in construction, a common form for dikes in the United States consists of two parallel rows of piles filled in between with brushwood or other materials not affected by water and protected at the sides from scour by an apron of fascines and stone.

3. Refuge Ports.—On large rivers, where vessels during high floods are exposed to injury from floating debris and ice floes, shelter can be provided in refuge ports, formed in a side recess under the protection of a solid jetty or embankment constructed in the river parallel to the bank. These ports are closed against floods at their upper end and have their entrance at the lower end facing downstream. There are numerous examples of such river harbours on the Danube, the Rhine, and in the rivers of North America. Many of them, made in the vicinity of towns, as at Düsseldorf, Ger., are inland ports of considerable size.

This problem takes a particularly acute form in connection with the works carried out after 1950 on the Don and Volga rivers in the U.S.S.R., where 200-mi.-long and 20-mi.-wide internal seas

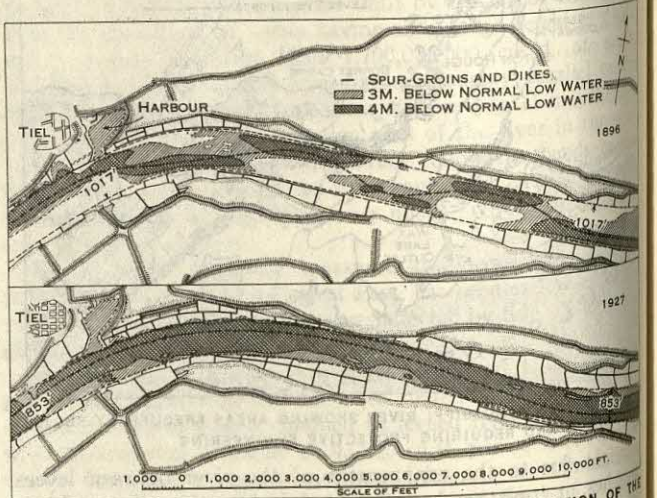

FIG. 4.—WAAL RIVER AT TIEL, NETH., SHOWING THE CONDITION OF THE TIEL REACH IN 1896 AND 1927

The regulation works completed in this reach in 1911 effected a permanent deepening of the channel and no dredging was necessary thereafter

have been created by building huge dams across the channels and valleys of the rivers. *See* WATER TRANSPORT, INLAND.

IV. CLEARANCE OF SMALL RIVER OUTLETS

Rivers with a small discharge flowing into the sea on an exposed coast are more or less obstructed at their outlet by drift of shingle or sand along the coast. When its flow falls very low in dry weather, the outlet of a river is sometimes completely closed by a continuous line of beach, any inland or tidal waters merely trickling through the obstruction; it is only on the descent of floods that the outlet is opened. In rivers that always have a fair freshwater discharge or a small freshwater flow combined with a tidal flow and ebb, the direct outlet is sometimes closed, and the flow is deflected parallel to the shore till it reaches a weak place in the line of beach, through which a new outlet is formed. Where the current keeps the outlet open, a bar is sometimes formed across the entrance by the littoral drift, reducing the navigable depth. (*See* HARBOURS; JETTY.)

The bar formed across the outlet of a river not heavily charged with sediment and flowing into a tideless sea can be lowered by carrying out solid jetties on each side of the outlet across the foreshore, so as to scour the bar by concentrating the issuing current over it. By combining slightly curved jetties with dredging, the depth at the entrance to the Swinemünde of the Oder River, Ger., was increased from 7 to 27 ft.; the approach channels to the Parnu River, Estonia, and other rivers flowing into the Baltic were deepened by jetties; and the outlet channels of some

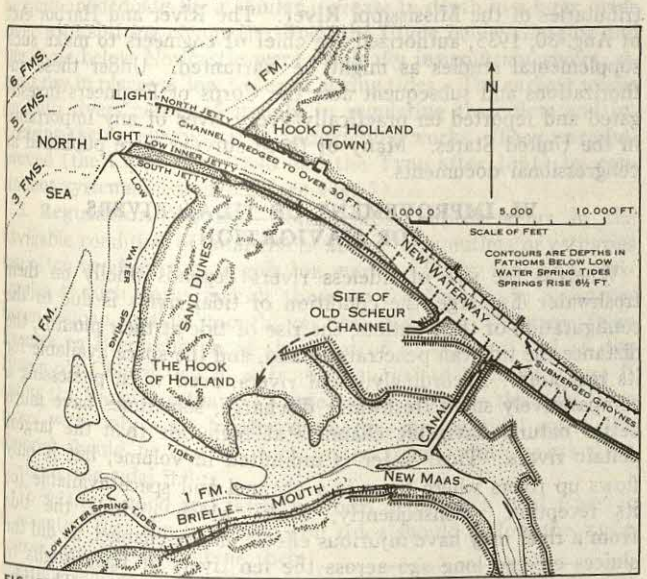

FIG. 5.—JETTY OUTLET OF THE MAAS RIVER INTO THE NORTH SEA. THE ARTIFICIAL CUT FOR THE MAAS RIVER THROUGH THE HOOK OF HOLLAND WAS BEGUN IN 1864

rivers flowing into the Great Lakes of North America were improved by permanent jetties and dredging.

Where the littoral drift is powerful enough to divert the outlet of a river (as in the case of the Yare River, which at one time was driven to an outlet 4 mi. S of its direct course into the sea at Yarmouth, Eng., and the Adour River in France, whose outlet, because of the violent storms of the Bay of Biscay, was liable to be shifted 18 mi. from its proper position), it proved practicable to fix as well as to deepen the outlet by means of jetties. Where such rivers flow into tidal seas, it is important to place the jetties sufficiently apart to avoid any loss of tidal influx, since the tidal flow assists the freshwater discharge in keeping the outlet open.

With rivers that flow into tideless seas, a moderate restriction of the width between the jetties increases the scour. The tortuous and somewhat shifting outlet channel of the Scheur branch of the Maas (Meuse) River, emerging onto a sandy coast where the rise of tide is small and obstructed at its mouth by a bar, was replaced by a straight cut across the Hook of Holland. The outlet across the foreshore is fixed in position by fascine-mattress jetties (*see* JETTY), the maintenance of the depth at the mouth by the tidal and fresh waters being aided by frequent dredging (fig. 5).

V. IMPROVEMENT OF DELTAIC OUTLETS OF TIDELESS RIVERS

Large rivers heavily charged with sand and silt, when their current is gradually arrested on entering a tideless or nearly tideless sea, deposit these materials as a constantly advancing fan-shaped delta through comparatively shallow diverging channels which convey the freshwater and sediment discharge into the sea. These deltaic channels deposit sediment in front of their outlets, forming bars which advance with the delta; their rate of progress seaward and the distance in front of each outlet are proportionate to the sediment load and discharge of the several channels. A channel dredged on the bar in front of an unimproved outlet of a deltaic river retains its depth for only a moderate period because of the deposit continually accumulating at the outlet.

1. Parallel Jetties.—The construction of parallel jetties, prolonging seaward the banks of an outlet channel, concentrates the scour of the issuing current on the bar at the outlet and under favourable conditions will procure and maintain an adequate depth for navigation. The requisite conditions for the success of this system are (1) a sufficient depth in the sea beyond the bar to allow for a considerable deposit of alluvium before the increased depth is interfered with, and (2) a littoral current carrying a portion of the alluvium away from the outlet. Both conditions retard the progression of the delta in front of the outlet and the inevitable formation of a new bar farther out. Thus the rate of advance of the delta in front of an outlet is proportionate to the size of the channel, and the length of the jetties required is proportionate to the discharge of the channel.

2. The Delta of the Danube.—The Danube traverses its delta in three branches. The northern one, though conveying nearly two-thirds of the discharge of the river, is unsuitable for improvement due to its splitting up into several channels and eventually flowing into the sea through 12 mouths of a small independent delta advancing about 250 ft. annually across a shallow foreshore. The central (Sulina) branch was selected for improvement in 1858 for reasons of economy in preference to the southern (St. George's) branch, which had a more favourable outlet and a better channel through the delta. The distance of the Sulina bar from the shore was only half that of the St. George's bar due to the much smaller discharge of the Sulina branch. The jetties, begun provisionally in 1858 and subsequently consolidated and somewhat extended, were completed in 1877. They increased the depth over the bar from an average of about 9 ft. before 1858 up to 20½ ft. in 1873. In 1894, however, the increasing draft of vessels rendered a greater depth necessary; the wide inshore portion of the jetty channel was therefore narrowed by inner parallel jetties, and a powerful suction dredger was set to work in the jetty channel and outside. The increase in depth to 24 ft. (1897) was fairly maintained up to 1907, when a second dredging operation became necessary to cope with the shoaling. The depth contours gradually advanced seaward, while the deepest channel was deflected northward by the action of current and waves. During World War I the decrease in depth, accelerated by interference with dredging, was so rapid that the navigable depth was reduced at one time to 18 ft. In 1922 the seaward extension of the jetties was commenced, leaving temporary gaps between the old heads and the new works, which were closed after the new channel had been opened for traffic. This extension of the jetties for about 6,000 ft. and dredging operations restored for the time being the ruling depth of 24 ft. in the direct channel. Later, a further extension of 2,000 ft. was made. The new jetties, like the original ones, are formed of fascine mattresses covered with stone rubble.

3. The Mississippi Delta.—The selection of the outlet of the South Pass of the Mississippi delta for improvement by parallel jetties in 1876–79, in spite of the Southwest Pass possessing a larger channel and a better depth over its bar, was due to motives

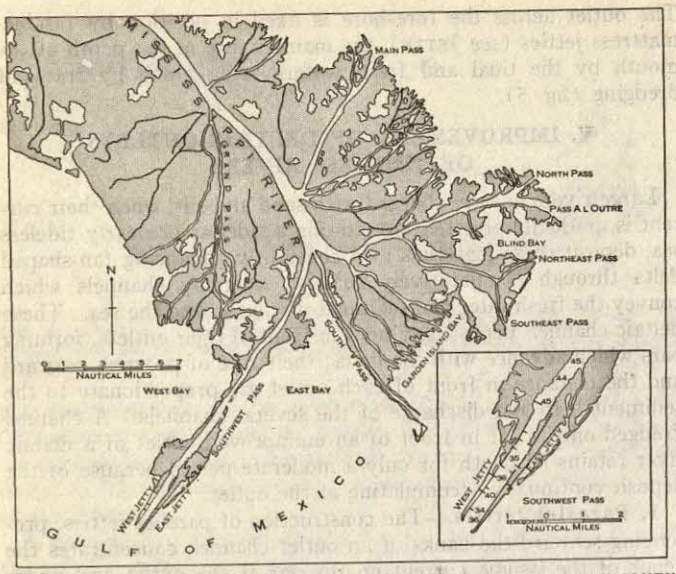

FIG. 6.—THE MISSISSIPPI DELTA (1946) SHOWING (INSET) PLAN OF SOUTHWEST PASS JETTIES

of economy, as the bar of the Southwest Pass was twice as far from the shore as that of the South Pass (fig. 6). Fascine-mattress jetties, 2¼ and 1½ mi. long, weighted with limestone and with large concrete blocks at their exposed ends, were constructed. The jetties, which were curved slightly southward at their outer ends to direct the sediment-bearing current more directly at right angles to the westerly littoral current, increased the depth of 8 ft. over the bar in 1875 to 31 ft. between the jetties and out to deep water. The prolonged flow of the river produced by the jetties, as at the Sulina outlet, carried most of the heavier sediment into fairly deep water, so that the greatest advance of the foreshore in front of the South Pass occurred in the 70-ft. line of soundings, though the shallower soundings also advanced. Mattresses and spurs constructed to counteract shoals in the jetty channel reduced its width from 1,000 to 600 ft., and eventually the jetties were rebuilt on lines reducing the channel width to about 650 ft. While the outer channel was deflected to the east and narrowed by the alluvium carried westward by the littoral current, dredging was required to maintain the stipulated central depth of 30 ft. and the 26-ft. depth for a width of 200 ft. out to deep water. After 1901 the combination of dredging and increased discharge at the South Pass widened the channel across the bar to about 600 ft. and deepened it to a minimum of 30 ft.

In order to provide for the increasing requirements of seagoing vessels, the formation of a channel 35 ft. deep and 1,000 ft. wide through the larger Southwest Pass and its 9-ft. bar to deep water in the Gulf of Mexico was begun at the end of 1903. The discharge through this pass is rather more than three times that through the South Pass, and the bar was double the distance seaward of the outlet. Converging jetties, about 5,600 ft. apart at their land ends and about 3,000 ft. apart at the seaward outlet, were substituted for the parallel jetties constructed at the South Pass, and suction dredging was relied upon to maintain the channel between the jetties and across the sea bar. The amount of channel dredging was found to be excessive, and in 1916 the project was modified by limiting the channel to a width of 2,400 ft. between two parallel interior bulkheads and the extension of the jetties to the 30-ft. contour beyond the bar. In 1923 the width was further restricted to 1,750 ft. by building spur dikes, or groins, and by 1924 a depth of 35 ft. was secured by dredging and aided by the scour of the current. The jetties, formed of fascine mattresses weighted with stone and capped with rubble and concrete, were extended seaward from time to time. In 1956 the east jetty extended about 4¾ mi. from the shore, and the west jetty had a length of about 3¾ mi. The amount of dredging required to maintain the 35-ft.-deep channel through the pass and over the bar was reduced after the width was narrowed.

Because the artificial improvement and simultaneous maintenance of two entrance channels to the Mississippi is essential for the uninterrupted passage of vessels, the project was modified so that the following channel dimensions were prescribed: Southwest Pass from Head of Passes to the outer end of the jetties, 40 ft. deep × 800 ft. wide; Southwest Pass bar, 40 ft. deep × 600 ft. wide; South Pass from Head of Passes to the outer end of the jetties, 30 ft. deep × 450 ft. wide; and South Pass bar, 30 ft. deep × 600 ft. wide. A dependable navigation channel 35 ft. deep is maintained via the Southwest Pass. A study and a hydraulic model experiment were under way in the mid-1950s, for the purpose of determining the works necessary to provide a dependable 40-ft. channel.

The U.S. Congress, through the River and Harbor Act of Jan. 21, 1927, assigned to the secretary of the army and to the chief of engineers, U.S. Army, the duty of making surveys, with a view to the formulation of general plans for the most effective improvement of navigable streams and their tributaries. The Flood Control Act of May 15, 1928, amplified this duty with respect to the tributaries of the Mississippi River. The River and Harbor Act of Aug. 30, 1935, authorized the chief of engineers to make such supplemental studies as might be warranted. Under these authorizations and subsequent acts the Corps of Engineers investigated and reported on practically every river of any importance in the United States. Many of these surveys were published as congressional documents.

VI. IMPROVEMENT OF TIDAL RIVERS FOR NAVIGATION

Whereas the size of tideless rivers depends wholly on their freshwater discharge, the condition of tidal rivers is due to the configuration of their outlets, the rise of tide at their mouths, the distance the tide can penetrate inland, and the space available for its reception. Accordingly, tidal rivers, even when possessing a comparatively small freshwater discharge, sometimes have much better natural navigable channels at high tide than the largest deltaic rivers. Tidal water is unlimited in volume, but it only flows up rivers where there is a channel and space available for its reception. Consequently, works which exclude the tide from a river may have injurious effects on the channel, as did the sluices erected long ago across the fen rivers of East Anglia to secure the low-lying lands from the inroads of the sea. The tidal influx is also liable to be reduced by the accretion resulting in an estuary from the construction of training works. The aims of all tidal river improvement should be to facilitate to the utmost the flow of the flood tide up a river, to remove all obstructions from

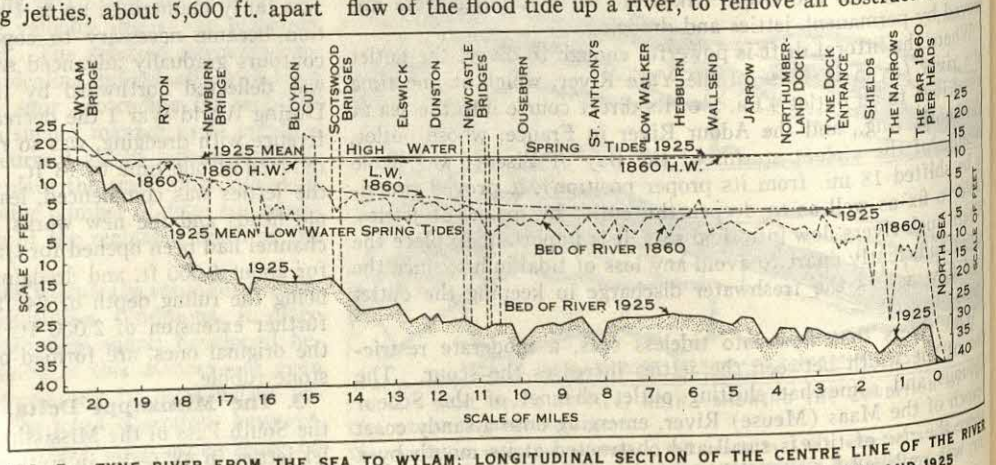

FIG. 7.—TYNE RIVER FROM THE SEA TO WYLAM: LONGITUDINAL SECTION OF THE CENTRE LINE OF THE RIVER SHOWING THE DEEPENING OF THE CHANNEL AND ALTERATION IN WATER LEVELS BETWEEN 1860 AND 1925

the channel so as to increase the scouring efficiency of the flood and ebb tides, and to reduce to a minimum the period of slack tide when deposit takes place.

1. Tidal Flow.—The progress of the flood tide up a river and the corresponding ebb are clearly shown by a diagram giving a series of tidal lines obtained from simultaneous observations of the height of the river at different points. The steep form assumed by the foremost part of the flood-tide lines on some rivers indicates the existence of a bore. This is caused by the sandbanks in the channel obstructing the advance of the flood tide till it has risen sufficiently in height to rush up the river as a steep, breaking wave, overcoming all obstacles and producing a sudden reversal of the flow and an abrupt rise of the water level. Such phenomena are observed on the Severn, the Seine, and the Amazon. A bore indicates defects in the tidal channel, which can be reduced only by lowering the obstructions and regulating the river. No tidal river of even moderate length is ever completely filled by tidal water, for the tide begins to fall at its mouth before the flood tide has produced high water at the tidal limit. Every improvement of the channel, however, expedites and increases the filling of the river, while the volume of water admitted at each tide is further augmented by the additional capacity provided by the greater efflux of the ebb, as indicated by the lowering of the low-water line.

2. Dredging.—The improvement of tidal rivers mainly by dredging is specially applicable to small rivers wide enough for navigation, like the Clyde and the Tyne in Britain, for they can be considerably deepened by an amount of dredging that would be quite inadequate for a similar increase in depth in a large, wide river with shifting channels. Both the Clyde below Glasgow and the Tyne below Newcastle were originally insignificant rivers, almost dry in places at low water of spring tides. The earliest works on both rivers consisted mainly in regulating their flow and increasing their scour by jetties and training works. They were improved (the Clyde after 1840 and the Tyne after 1861) by continuous systematic dredging (*see* Fig. 7).

3. Regulation Works.—Considerable improvements in the navigable condition of tidal rivers above their outlets or estuaries can often be effected by regulation works aided by dredging. Examples of such works include those on the Nervión in Spain between Bilbao and its mouth, on the Weser in Germany from Bremen to Bremerhaven at the head of its estuary, and on the Huang-p'u Chiang in China from Shanghai to Wusung where it enters the Yangtze estuary. These works resemble those on large rivers with only a freshwater discharge, but on tidal rivers the channel should be trained with an enlarging width seaward to facilitate the tidal influx.

To secure a good and fairly uniform depth on a tidal river, it is essential that the flood and ebb tides should follow the same course in order to combine their scouring efficiency and form a single, continuous, deep channel. In wide, winding reaches, however, the flood tide in ascending a river follows as direct a course as is practicable, and on reaching a bend the main flood-tide current, in being deflected from its straight course, hugs the concave bank. Keeping close alongside the same bank beyond the bend, it cuts into the shoal projecting from the convex bend of the bank higher up, forming a blind shoaling channel. This effect is due to the flood tide losing its guidance, and consequently its concentration, at the change of curvature beyond the termination of the concave bank, where it spreads out and passes gradually over, in its direct course, to the next concave bend along the opposite bank. The ebb tide, on the contrary, descending the river, follows the general course of the freshwater discharge in all rivers, its main current keeping close along the concave bank and crossing over to the next concave bank below. The main currents of the flood and ebb tides in such reaches act quite independently between the bends, forming channels on the opposite sides of the river and leaving a central intervening shoal or bar crossing.

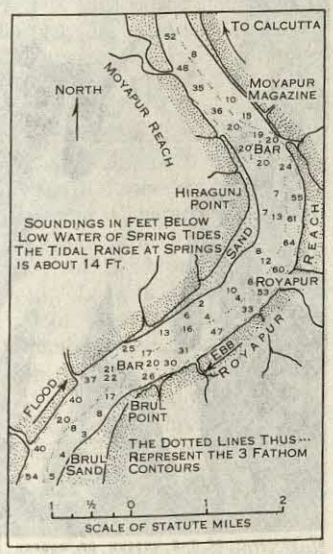

FIG. 8.—HOOGHLY RIVER SHOWING THE MOYAPUR AND ROYAPUR BAR CROSSINGS (1946)

In tidal rivers the main ebb current, being reinforced by the freshwater discharge, generally forms the navigable channel, which is scoured out during floods. Narrowing the river between the bends to bring the two channels together would unduly restrict the tidal flow. In a river such as the Hooghly (*see* Fig. 8) in India, dependent on the tidal flow for the maintenance of its depth for two-thirds of the year, with channels changing with the wet and dry seasons and even shifting their position from day to day, deepening by dredging can never be permanent.

The training and dredging works carried out in the Huang-p'u Chiang after 1906 successfully deepened the alluvial channel to about 30 ft. at low water up to Shanghai, including the bar crossing in a wide reach between Gough Island and Wusung, where formerly the low-water depth was no more than 13 to 15 ft. The problems encountered differed from those of the Hooghly in that the volume of the land-water runoff was relatively small, and the concave riverbank above the crossing was being rapidly eroded, accentuating a sharp bend below it.

On the Mersey, the erosion of the Taylor's bank, forming the concave side of the main sea channel, threatened to intensify the bend to a dangerous degree. It was countered by revetting with stone the concave face of the bank below low water.

4. Effect of River Deepening on Tidal Levels.—The general effect of deepening and regulating the tidal section of a river by dredging and the removal of obstructions is to facilitate the propagation of the flood tide up the channel and the efflux of the ebb. Consequently such works often result in lowering the low-water level and raising the high-water level in the upper part of the improved channel and sometimes above it.

The average high-water level in the Thames at Chelsea increased 8 in. between 1890 and 1927, a period when dredging was carried out on a large scale in the lower reaches of the river. The maximum flood levels also increased steadily after 1874, when a tide rose 16 ft. 10 in. above ordnance datum (a horizontal plane from which water elevations and depths are measured) at Westminster, considerably higher than any previous record. This height was exceeded on several later occasions, including that of the disastrous tidal flood of Jan. 6–7, 1928, when 18 ft. 3 in. above ordnance datum was reached at London Bridge (equivalent to about 18 ft. 5 in. at Westminster).

5. Estuary Training Works.—Many tidal rivers flow through bays, estuaries, or arms of the sea before reaching the open sea, as, for instance, the Mersey through Liverpool Bay; the Liffey through Dublin Bay; the Thames, the Ribble, the Dee, the Shannon, the Seine, the Scheldt, the Weser, the Elbe, and the Yangtze through their respective estuaries; the Yorkshire Ouse and Trent through the Humber estuary; the Garonne and Dordogne through the Gironde estuary; and the Clyde, the Tay, the Severn, and the St. Lawrence through firths or arms of the sea. These estuaries vary greatly in tidal range, the distance inland of their ports, and their facilities for navigation. Some possess a very ample depth in their outer portion, though they generally become shallow toward their upper end. Dredging often suffices to remedy their deficiencies and to extend their deepwater channel. Thus dredging was required in parts of the Thames and Humber estuaries and on the Elbe below Hamburg to provide for the increasing draft of vessels, and the Mersey bar in Liverpool Bay, about 11 mi. seaward of the actual mouth of the river, was lowered by suction dredging from a depth of about 9 ft. down to about 26 ft. below low water of equinoctial spring tides.

A remarkable improvement was effected in the navigable condition of the upper portion of the Seine estuary by training works begun in 1848; in place of a shallow, intricate channel through shifting sandbanks, a stable channel was provided down to Saint-Sauveur, rendering access as far as Rouen for vessels drawing up

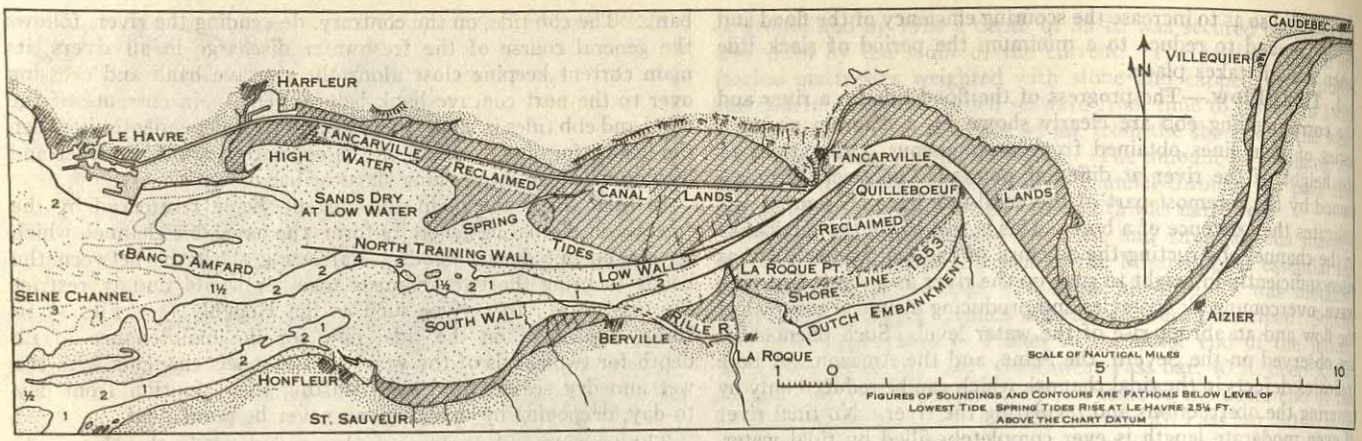

FIG. 9.—TRAINING WORKS IN THE SEINE ESTUARY (1946)

to 23 ft. at high-water neaps (occurring at the first and third quarters of the moon) and up to 27 ft. at high water of spring tides. Large tracts of land were reclaimed in the upper estuary, and the reduction in tidal capacity due to the reclamations, together with the fixing and undue restriction in width of the channel, resulted in large accretions at the back of the training walls and at the sides of the estuary beyond them, besides an extension of the sandbanks seaward (fig. 9).

Experience has proved that training works through sandy estuaries, by stopping the wanderings of the navigable channel, produce an increase in its depth and, consequently, in the tidal scour for maintaining it. This scour, however, being concentrated in the trained channel, is withdrawn from the sides of the estuary, which in its natural condition is stirred up periodically by the wandering channel. Therefore, accretion occurs in the parts of the estuary from which the tidal scour and freshwater discharge have been permanently diverted.

This accretion reduces the tidal capacity of the estuary and, producing a diminution in the tidal volume passing through the outlet, should not be raised more above low-water level than absolutely necessary to fix the channel. Experiments with a model, molded to the configuration of the estuary under consideration and reproducing in miniature the tidal ebb and flow and freshwater discharge over a bed of very fine sand, in which various lines of training walls can be successively inserted, are capable in some cases of furnishing valuable indications of the respective effects and comparative merits of the different schemes proposed for works.

6. Gravity Flow.—Much attention is devoted in modern literature on river hydraulics to the phenomena known as gravity (density) currents, which are currents of heavier liquids in currents of lighter liquids. Examples are heavily silt-laden currents in clear water lakes, and salt water currents at the estuaries of rivers moving upstream beneath the sweet water current moving downstream, as for instance in some Scottish lochs and, very probably, in the Nile.

RIVERA, DIEGO (1886–1957), Mexican mural painter, was one of the leaders of the revolutionary movement in public wall painting that began in Mexico in the 1920s. He was born in Guanajuato, Gto., Mex., on Dec. 8, 1886. His politically liberal father early encouraged his son's artistic bent by providing him with a studio before he was able to read and by sending him to art classes at ten. Before 1906 Diego Rivera had studied under such Mexican masters as the romantic landscape painter José María Velasco and the French-trained classicist Santiago Rebull. He then went to Spain on a government scholarship, and at the beginning of the Madero revolution in Mexico, he made an exhibition at home of his somewhat conventional Spanish canvases. Between 1911 and 1920 he lived mostly in Paris, producing hundreds of Cubist paintings and drawings in a manner largely derived from the Spanish master Picasso—though his own work retained many easily recognizable objects.

After making a firsthand study of fresco painting in Italy, Rivera returned to Mexico with a newly wrought classical and didactic style, graced with lyrical elements, and began to make his famous proletarian frescoes. In the early 1930s Rivera was the centre of wide political controversy in the United States. A mural he painted for the Detroit (Mich.) Institute of Fine Arts in 1932 was criticized as irreligious and his mural "Man at the Crossroads" (executed for Rockefeller Centre, New York city),

"AGRARIAN LEADER ZAPATA" BY RIVERA IN 1931, A VARIANT OF A FRESCO IN THE CORTÉS PALACE, CUERNAVACA, MEX.; MUSEUM OF MODERN ART, N.Y.

which included a portrait of Lenin, also was the subject of strong protests. The former was defended by Institute authorities; the latter was eventually removed and reconstituted at the Palace of Fine Arts in Mexico City.

Among Rivera's most distinguished frescoes were those painted at the National School of Agriculture, Chapingo, D.F., with its decorative studies of the nude figure, and at the Cortés palace in Cuernavaca, with its stylized and bittersweet story of the conquest of Mexico. In Mexico City he painted the lyrically landscaped staircase connecting tall frescoed corridors in the Ministry of Education; in the National palace he portrayed Aztec history in archaistic forms and cold colours; and in the Social Security Hospital No. 1 he returned to his earlier lyrical style.

Rivera died Nov. 25, 1957, in Mexico City.

RIVERA, a department in northern Uruguay on the Brazilian border; also the departmental capital. Area of the department 3,795 sq.mi. (9,829 sq.km.). Pop. (1963) department 75,826; city (1963) 41,266. Rivera has good pastureland and is noted for its sheep and cattle ranches. There is also an increasing amount of agriculture, with leading crops including rice, sweet potatoes, corn, peanuts, wheat, and fruit.

The city of Rivera is across the border from the Brazilian city of Santa Ana do Livramento, and the two enjoy an active economic and cultural interchange. (M. I. V.)

RIVER BRETHREN: *see* BRETHREN IN CHRIST.

RIVERINA, a district occupying the central southern portion of New South Wales, Austr., bounded on the south by the Murray River and on the north by the Lachlan-Murrumbidgee from about Hillston down to the Murray confluence. The eastern boundary runs from the Lachlan above Hillston to Corowa on the Murray, but the lower slopes of the southern tableland are sometimes included in the Riverina. Except in the east, the whole district is flat, with the rivers falling only ten inches a mile in the east and four to five inches in the west. The rivers meander across vast alluvial plains, periodically flooding and forming distributaries and billabongs (lagoons); in their upper reaches in the east they offer many sites for dams. The soil is prevailingly rich. The climate is generally mild and warm but the summers are hot and dusty and rainfall is variable. Average annual temperatures range from 24° to 9.5° C (75° to 49° F), with extremes of from 47° to −6.5° C (117° to 20° F); the average annual rainfall ranges from 12 in. (30 cm.) in the northwest to 25 in. (62 cm.) in the southeast.

The greater part of the Riverina provides good natural fodder for sheep grazing and was originally a pastoral area, but improvements in farming (particularly in wheat breeds and in dry farming) and the development of water conservation projects led to great increases in cultivation. Along the southeastern slopes, with their cooler temperature and more reliable rain, much arable farming is carried on, including fruit growing and some dairying. Farther west mixed wheat and sheep farming is characteristic. The great wealth of the Riverina, however, lies in its irrigation farming, the bulk of irrigated land being along the Murray and Murrumbidgee, with a smaller area on the Lachlan. The Murrumbidgee irrigation areas consist of about 450,000 ac. served with water from Burrinjuck Dam and Berembed Weir, from which the irrigation channels lead. Leeton (pop. [1961] 5,354) and Griffith (7,696) comprise about 2,000 irrigation farms and a total population of about 26,000 people established in a once sparsely inhabited pastoral area. The farms are either horticultural (principally citrus fruits, apricots, peaches, wine grapes, and vegetables) or mixed (rice, wheat, oats, meat, and wool). The industry of the area is restricted to processing local products. There are wineries, canneries (including the largest in Australia), rice mills, and fruit-packing houses. Smaller irrigation areas are at Hay on the Murrumbidgee and Tullakool on the Murray. Larger areas on the Murray (Berriquin, Wakool, Denimein, and Denibooth) and on the Murrumbidgee (Waa Waa and Tabbita) are farmed less intensively, water being allotted on the basis of the irrigation of a portion only of each holding. The Snowy Mountains hydroelectric project was begun in 1949 to make available a much larger volume of water for irrigation.

The area of the Riverina is 26,533 sq.mi., with a population in 1961 of 89,994. The chief towns are Albury (18,621) and Wagga Wagga (22,029 [mun.]); others are Leeton, Griffith, Junee, Narrandera, and Hay. There were about 7,370 rural holdings (16,200,000 ac.) in the mid-1960s, with about 1,500,000 ac. under cultivation, and a further 1,300,000 ac. under sown pastures. The farming is intensive and the pastures support about 8,500,000 sheep, producing much of the best wool of New South Wales. The entire rice crop of Australia is grown in the Riverina. The eastern valleys have in the past yielded considerable quantities of gold, both alluvial and reef, especially at Adelong and Gundagai, but production is now negligible. In 1915 soft black subbituminous coal was discovered near Oaklands, but production was always small and after the late 1950s almost negligible. The area also produces some tin and gypsum. (R. M. HL.)

RIVER ROUGE, a city of Michigan, U.S., in Wayne County, bordering Detroit on the southwest, is located on the Detroit and Rouge rivers. The available rail and water transport encouraged industrialization, and manufactures include paper, ships, gypsum products, and steel. Most of the residents are employed by local firms. Zug Island, a highly industrialized 400-ac. site formed by a canal dredged between the Rouge and Detroit rivers, is located in the northeast corner of the city. The concentration of industry results in favourable tax rates for homeowners and, during normal periods, a solvent municipal economy. Although a site of early French settlement, the nucleus of a town did not appear until 1817 when a toll bridge was erected over the Rouge River at River Road (Jefferson Avenue). With the advent of industrialization, River Rouge was incorporated as a village in 1899. During World War I, mainly because of the construction of the Ford Motor Company's River Rouge plant nearby, a population influx occurred which, in 1921, resulted in the incorporation of River Rouge as a city. For comparative population figures *see* table in MICHIGAN: *Population.* (E. K. R.)

RIVERS, ANTHONY WOODVILLE (WYDEVILLE), 2ND EARL (*c.* 1440–1483), brother-in-law of the English king Edward IV, was the eldest son of Sir Richard Woodville (afterward Earl Rivers) and Jacquetta of Luxembourg, widow of John duke of Bedford. He married (*c.* 1461) Elizabeth, daughter and heiress of Thomas, Lord Scales; and in 1464 the secret marriage of his sister Elizabeth to Edward IV established the Woodvilles in preeminence at court.

Yet Anthony's part in government, as opposed to his political influence, does not seem to have been very great. His reputation was rather as the leader of those young men who were fascinated by the splendours of the court of Burgundy and thought there was "never non lyek to it save kyng Artourys cort"; and his spectacular tournament in 1467 with Anthony, the Grand Bastard of Burgundy, was only one among deeds of arms which made him an international figure. The attack on the Woodvilles by the duke of Warwick in 1469 led to his father's death and his own succession to the earldom. Woodville accompanied Edward IV in his temporary exile, fought at the Battle of Barnet (April 1471) after Edward's return, and held London for him at the time of the Battle of Tewkesbury (May 1471). But these events weakened his position. A certain measure of otherworldliness seems to have overtaken him, to the king's fury; in 1471 it was reported as a result that "he may do leest with the gret mastyr." Although he commanded a force in Brittany in 1472, took part in Edward's French expedition in 1475, and was put forward as a proper candidate for the hands of Mary, duchess of Burgundy, in 1477, and of Margaret, sister of James III of Scotland, in 1479, "the stormes of fortune" had evidently been too much for his morale. By 1479 William Caxton wrote of him "it semeth that he conceiveth wel the mutabilite and the unstablenes of this present lyf and that he desireth with a greet zele and spir-

ituell love our goostly helpe and perpetuel salvacion" (Epilogue to *Cordyale*). To this end he had sought to campaign against the Saracens in Portugal in 1471, had gone on pilgrimage to Santiago de Compostela in 1473 and to Rome and other holy places in Italy in 1475; to this end also he began to translate from French a series of moralistic and devotional works, *The Dictes or Sayengs of the Philosophres*, the *Moral Proverbes* of Christine de Pisan and *Cordyale*, a treatise of the Four Last Things, all of which were printed by Caxton between 1477 and 1479. He also composed "diverse balades ayenst the seven dedely synnes."

Woodville had become governor to the prince of Wales in 1473; but after the death of Edward IV (April 1483), Richard, duke of Gloucester, protector of the kingdom, had him arrested on a barely possible charge of treason and he was executed without trial on June 25, 1483. Fortune's wheel had turned once more; on the eve of his execution, Rivers wrote her possibly the only poem of his that has survived.

Scofield, *The Life and Reign of Edward IV*, 2 vol. (1923); *The Prologues and Epilogues of William Caxton*, ed. by W. J. B. Crotch for the Early English Text Society (1928). (P. S. LE.)

RIVERS, RICHARD WOODVILLE (WYDEVILLE), EARL (d. 1469), father of Elizabeth Woodville, queen of Edward IV of England, was the son of Richard Woodville (d. *c.* 1441), a squire who served with distinction in the Hundred Years' War. Richard the younger also served in this conflict and won a reputation as an accomplished knight. He was outstandingly handsome and founded his fortunes by marrying, between September 1435 and March 1437, Jacquetta of Luxembourg, widow of John, duke of Bedford. In 1448 he was created Baron Rivers. A staunch supporter of Henry VI, he was in 1459 stationed at Sandwich to prevent a landing by Richard Neville, earl of Warwick, from Calais; but in January 1460 Warwick captured him in a surprise raid. He escaped in time to fight for Henry VI at Towton (March 29, 1461), but soon afterward made his peace with Edward IV. His fortunes were more than restored by the marriage of his eldest daughter Elizabeth to Edward on May 1, 1464. Through royal favour most of his five surviving sons and eight daughters were married into the noblest families, and Rivers himself was in 1467 made constable of England. This upstart family soon aroused the hatred of the old nobility, especially the Nevilles, and one of Warwick's aims in 1469 was the destruction of the Woodvilles. After the royalist defeat at Edgecote (July 1469) Rivers and his second son, Sir John Woodville, were captured at Chepstow, given up to Warwick, and beheaded at Kenilworth on Aug. 12, 1469.

See J. H. Ramsay, *Lancaster and York*, 2 vol. (1892); *The Complete Peerage*, vol. xi, ed. by G. H. White (1949). (A. R. M.)

RIVERS, THOMAS MILTON (1888–1962), U.S. pioneer in virology (the study of viruses) and a key figure in the development of poliomyelitis vaccines, was born in Jonesboro, Ga., on Sept. 3, 1888. He graduated from Emory College, Oxford, Ga., in 1909 and the Johns Hopkins School of Medicine in 1915. At that time viruses were little understood; Rivers' interest in them was confirmed by his work as an investigator, in 1918, of a type of pneumonia then prevalent as a complication of measles. In 1922 he joined the Rockefeller Institute for Medical Research, New York City; from 1937 until his retirement in 1955 he was director of its affiliated hospital. At the institute he worked on influenza, chicken pox, and other viral infections, and campaigned for the recognition of viruses as distinct causative agents of disease. In 1938 he was named chairman of the virus research committee of the National Foundation for Infantile Paralysis (later the National Foundation–March of Dimes) and after 1955 served full time as its vice-president for medical affairs. Rivers was credited with outlining and recruiting support for the long-range research program that led to discovery of the Salk and Sabin antipolio vaccines. He died in New York City on May 12, 1962. (M. FI.)

RIVERS, WILLIAM HALSE RIVERS (1864–1922), English physician, psychophysiologist, and anthropologist, who helped lay the groundwork for modern kinship terminology (*q.v.*), was born on March 12, 1864, at Luton, near Chatham, Kent. Completing his medical training at St. Bartholomew's Hospital, London, he then devoted his attention to problems of physiological psychology—notably the nature of colour vision; and his work in this field and, later, on the influence of drugs (particularly alcohol) and on mental fatigue quickly established his reputation. In 1897 he became director of the first British laboratory for experimental psychology (opened by J. Sully at University College, London); and in the same year he was appointed lecturer on the special senses at Cambridge, where, with C. S. Myers, he was the effective founder of experimental psychology in that university.

Toward the close of 1898 he joined the Cambridge expedition to the Torres Strait with A. C. Haddon, C. S. Myers, and W. McDougall. With them he administered a number of tests of sensory functions to the Melanesians, and became keenly interested in anthropological field work. In 1901–02 he made a firsthand study of the Toda (*q.v.*), a polyandrous group in southern India, and later paid several visits to Melanesia. In 1908 he was elected fellow of the Royal Society.

His two main anthropological publications—*The Todas* (1906) and his monumental *History of Melanesian Society* (two volumes, 1914)—are of enduring interest. His main contribution was his demonstration of the relation between kinship names and social organization. On the outbreak of World War I he became neurological consultant to the British Army, and for the remainder of his life he devoted himself to medical psychology. His critical discussion of Freudian theories in his *Instinct and the Unconscious* (1920) did much to encourage a sympathetic attitude toward psychoanalytic doctrines. He died on June 4, 1922.

See for biographical reviews *The Eagle*, vol. xliii, pp. 2–14 (1924); G. H. Brown, *Lives of the Fellows of the Royal College of Physicians of London, 1826–1925* (1955). (CY. B.)

RIVERSIDE, a city of southern California, U.S., is situated on the Santa Ana River at the base of the San Bernardino range, about 55 mi. SE of Los Angeles; the seat of Riverside County. Pop. (1960) 91,922; San Bernardino-Riverside-Ontario standard metropolitan statistical area (Riverside and San Bernardino counties), 809,782. (For comparative population figures *see* table in CALIFORNIA: *Population.*)

Despite nearness to Los Angeles, the city has a strongly individual character, marked by extensive planting of palm, pepper, and orange trees. In the 1960s housebuilding was diminishing the orange groves, but these were still extensive.

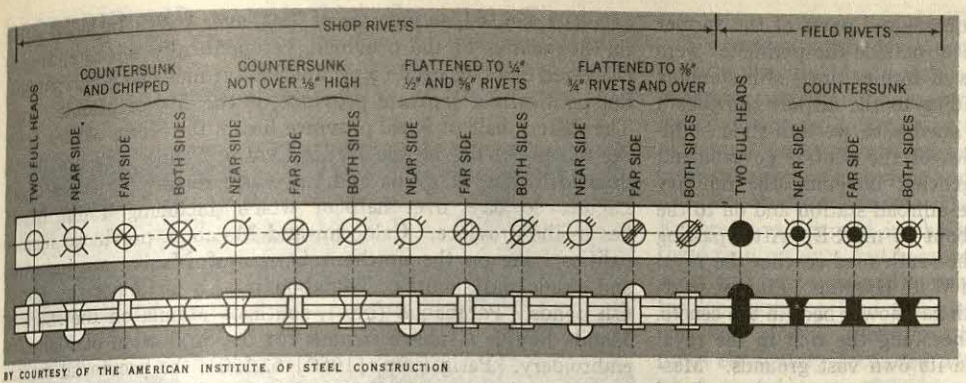
Settlement in the area began in the 1870s, sponsored by Judge John W. North of Tennessee. Street names (Victoria, Prince Albert, Dufferin) commemorate the largely British and Canadian character of early immigration. The original idea of a silk-cultivating colony was replaced in 1878 by the successful propagation of the Washington navel orange tree; the parent tree still survives. Riverside was incorporated in 1883 and adopted the city-manager form of government in 1953.

The city is the location of a general campus of the University of California, including the citrus experiment station (founded 1907), a college of letters and science (1954), and a graduate school (1960). Other educational institutions include Riverside City College (Jr.) (1916), California Baptist College (1955), and Sherman Institute (1901), a school for Indians. Its unique hotel, the Mission Inn, is a show place of Spanish-style architecture.

Riverside's climate is dry and warm. Its economy, formerly based almost entirely on oranges, is diversified and includes the manufacture of aircraft motors, precision instruments, air-conditioning equipment, paints, and building materials. It remains, however, an important food distribution centre with extensive citrus-fruit and vegetable packing. (A. C. TR.)

RIVET, a headed pin or bolt used as a permanent fastening in metal work. A head is formed on the plain end of the pin or bolt by hammering or by direct pressure. Cold riveting is practicable for small rivets of copper, brass, aluminum, iron, or steel, but the larger iron and steel rivets have to be heated in order to secure rapid and easy closing.

Machine riveting in small sizes is done either with a power press, where the ram works a snap and closes the tail with a blow, or with a rotary rivet-spinning machine, in which hard



BY COURTESY OF THE AMERICAN INSTITUTE OF STEEL CONSTRUCTION

CONVENTIONAL SYMBOLS USED TO INDICATE RIVETING IN PLAN AND ELEVATION ON ALL STRUCTURAL DRAWINGS

steel rollers spin the tail quickly and noiselessly into shape. In engineering structures, machine riveting is employed whenever practicable, using portable pneumatic hammers or fixed or portable hydraulic riveters.

The various shapes of rivet heads or tails include the countersunk head, which is beaten flush into a conical recess in the plate; the cup or round head; the pan head, which has sloping sides and a flat top; the conical head, with sloped sides ending in a point; and the thin flat head. Bifurcated rivets for belts and harnesses have thin heads, but the tails are split and opened like a paper fastener. Often gas or electric welding has been substituted for riveting in the case of hollow ware and other sheet-metal products. Electric welding is an alternate method for the connection of structural members such as columns and beams in building construction. *See* also PNEUMATIC TOOLS.

RIVIERA, the Mediterranean coastland between Cannes in France and La Spezia in Italy. The French section comprises part of the Côte d'Azur (which extends farther west), while the Italian is known as the Riviera di Ponente and the Riviera di Levante, respectively west and east of Genoa. Effectively sheltered to the north by the Maritime Alps and Ligurian Apennines, the district has exceptionally mild winters (January mean 9° C; 49° F), brilliant, hot summers (July mean 24° C; 76° F) and much sunshine throughout the year. Rain usually falls only on about 60 days in the year, and on the coast itself snow is almost unknown. Many delicate plants, including the pomegranate, agave, mimosa, and some types of palm, flourish; flowers are grown out of season for export in large quantities to northern markets. The favourable climate, the grandeur of the rugged coastal scenery, and the attractions of the sea have drawn the leisured rich, especially for wintering, since before the mid-19th century.

The popularity of Cannes dates from 1834, when Lord Brougham, avoiding a cholera epidemic in Nice, stayed there instead and, returning regularly for the next 30 years, set the fashion. Modern transport has increased the influx of tourists; luxury villas and hotels are now mixed with resort facilities of a more popular kind. Monte Carlo in the tiny principality of Monaco (*q.v.*) offers additional attractions for high living. From west to east the main centres of this beaded coastal urban development are Cannes, Juan-les-Pins, Antibes, Nice, Menton, Bordighera, San Remo, Alassio, Santa Margherita, Rapallo, Sestri Levante, and Levanto. A three-tiered system of motor roads (the Corniches) runs between Nice and the Italian frontier at Menton. The highest, Grande Corniche, constructed by Napoleon I to replace the Roman road, passes the picturesque village of La Turbie, with its Roman remains, and the 10th-century Roquebrune Castle, and overlooks Monaco from a height of more than 1,400 ft. (430 m.). The lowest Corniche, built in the 18th century by a prince of Monaco, connects the coastal resorts; while the middle road, opened in 1939, was created for the tourist industry and passes by the perched village of Eze. The railway burrows through the projecting limestone headlands by numerous tunnels.

(AR. E. S.)

RIVIÈRE, JACQUES (1886–1925), French essayist, whose delicacy of perception and acute sense of responsibility had a profound influence on the writers associated with the *Nouvelle Revue française* (*N.R.F.*), was born in Bordeaux on July 15, 1886. He was secretary of the *N.R.F.* immediately before World War I and became editor in 1919. Among his friends were André Gide, Paul Claudel, Charles Péguy, and Jacques Copeau, and he was an early admirer of Marcel Proust. He himself aspired to write an analytical novel (*Aimée,* 1922; and the unfinished *Florence,* published posthumously, 1935). His personal anxieties and aspirations are best reflected in his letters to Alain-Fournier (his brother-in-law), in his correspondence with Claudel, published after his death, and in his essay *À la trace de Dieu* (1925). He was brought up a Catholic, but later an oppressive awareness of "the reality of nonbeing" prevented him from accepting the Christian faith, much as he would have liked to do so. He died in Paris, on Feb. 14, 1925, before the promise of his work had been fulfilled. His other writings include *L'Allemand* (1918), *Carnet de guerre* (1929), *Études* (1912), and *Nouvelles Études* (published posthumously, 1947).

See the commemorative number of the *Nouvelle Revue française,* vol. 24 (1925). (A. PE.)

RIYADH (AR RIYAD), the capital of Saudi Arabia, in the province of Najd (*q.v.*), lies 535 mi. (860 km.) NE of Jiddah (on the Red Sea), and 250 mi. (400 km.) SW of Ad Dammam (on the Persian Gulf) with which it has been connected by a railroad (350 mi.) since 1951. The first census, taken in 1962, gave the population of Riyadh as about 170,000, a figure considerably lower than earlier unofficial estimates but high enough to make Riyadh the largest city in the kingdom.

In 1824 Riyadh became the capital of the Saudi state, which was then confined to the region of Najd. The ruins of the former capital, Ad Dir'iyah, still tower above Wadi Hanifah 10 mi. NW of Riyadh. The discovery of oil and the resulting spread of modern means of communication have revolutionized the life of the desert kingdom. The general tendency has been toward the development of large urban communities at the expense of what was a tribal and oasis economy. Riyadh best illustrates this process. The old walled town with about 30,000 inhabitants, forming an irregular square of 600–700 yd. to the side, remained intact until the end of World War II, though a few fairly large royal dwellings made their appearance outside the perimeter toward the end of that period. By 1951 the population had grown to about 60,000. After that time the walls were torn down and many old houses destroyed to make room for modern buildings. Expansion proceeded in every direction, over uprooted date groves and past neglected and dying palms and out into the desert, to cover an area estimated at about 40 sq.mi. (104 sq.km.). The character of the population, once exclusively Najdi, has changed substantially with the influx of people from other parts of the kingdom and from other Arab countries, such as Syria, Lebanon, Egypt, and Yemen, in search of employment and commercial opportunity. Although the presence of these elements has brought about a relaxation of the old puritan way of life, some aspects survive, as may be seen in the ban on public cinemas and the discouragement of smoking in the streets of the more ancient quarters.

In the centre of old Riyadh the king's town palace, once said to represent all that is best in modern Arabian architecture, has made way for a large concrete structure of cubist affinities, providing offices for the local provincial administration. Opposite it the old Wahhabi mud-brick mosque with its low minaret disappeared in favour of a concrete mosque 200 yd. long and wide, with two tall minarets equipped with loudspeakers to relay the calls to prayer. The palace square is a busy crossroads from which broad asphalt streets, lined with shops, run east, west, south, and north into the modern suburbs of greater Riyadh. The fort

of Al Mismak, not far from the square, and parts of the former royal palace complex of Al Murabba' outside the perimeter were among the few important buildings of former times still standing in the 1960s. The north road leading to the airport provides a good view of Al Murabba' and is lined with western-style buildings housing most of the ministries of the central government, hotels, hospitals, and military agencies, including the military college. The east road leads to the railroad station and on to the large military base in Al Kharj, about 50 mi. SE. After passing through new residential suburbs, the south road reaches the royal country palace on the right bank of Wadi Hanifah. Finally, westward, a broad divided highway, with gay flower beds in the centre, runs past the mansions of the princes and the rich to the royal palace of Al Nasiriyah, standing in its own vast grounds. Massive gates guard the eastern and western entrances, and tree-lined avenues crisscross the interior. The main buildings are of pink-tinted concrete in a mixture of styles ranging from pseudo-Moorish to modern European, but the general effect is not unpleasing.

More than half the buildings in Riyadh are equipped with main water or electricity or both. Water supply remains a serious problem because of the rapidly growing population, the extensive use of water for gardens and green spaces, and the steadily subsiding underground water table.

Set on high ground above Wadi Hanifah, which is waterless most of the year, Riyadh and its vicinity have almost no agriculture, and provisions must be imported from other parts of the country and from abroad. The climate is dry and invigorating, with occasional sandstorms. There is no heavy industry.

There has been extensive development in education, public health, and the social life of the community. King Sa'ud I University (now Riyadh University) was founded in the suburb of New Riyadh in 1957. Various international conferences, including sessions of the Arab League, are held in the city.

Riyadh is linked with Ad Dammam via Khurays by an asphalt road, and the remaining portion of the transpeninsular highway, running to Mecca and Jiddah, is under construction. Saudi Arabian Airlines operates regular flights from Riyadh to Jiddah, Dhahran, and other centres in the kingdom, and the Riyadh airport is also used by aircraft of other countries, particularly during the season for the Mecca pilgrimage. A radio-telephone network puts Riyadh in direct touch with the outside world.

RIZAL, a province of the Philippines, in central Luzon, northeast and south of Manila. It is named after the Philippine national hero, José Rizal. Area 791 sq.mi. (1,971 sq.km.); pop. (1960) 1,456,362, an increase of 75% over 1939. Included within the boundaries of the province, yet politically separate, are the chartered cities, Quezon (*q.v.*) and Pasay; included geographically, but politically a separate province, is the city of Manila (*q.v.*). The eastern half of Rizal province lies in the Sierra Madre, while the remainder lies on the fertile Central Plain. The province is drained by the Marikina and the Pasig rivers; the latter drains Laguna de Bay, over half of which, including Talim Island, lies in the province. Caloocan and Malabon, provincial municipalities lying on the northern border of Manila, are industrial and residential suburbs. Malabon is also an important site of fish ponds. Parañaque (*q.v.*), south of Manila on the shore of Manila Bay, is a suburb famous for the production of Philippine embroidery. Pasig (pop. [1960] 62,130), the provincial capital, is an important trading centre between Manila and Laguna de Bay and is known for the manufacture of shoes. Pasay City (sometimes called Rizal City; pop. [1960] 132,673) lies between Manila and Parañaque on the shore of Manila Bay. It is a major residential suburb of Manila and is well known for the nightclubs lining the beautiful waterfront along Dewey Boulevard. Ft. William McKinley, immediately east of Pasay City, is a former U.S. Army reservation which was returned to the Philippines in 1947; it is the site of a large cemetery dedicated to the dead of World War II.

(R. E. He.)

RIZAL Y MERCADO, JOSÉ (1861–1896), Filipino patriot and inspirer of Philippine nationalism, sought to prove throughout his career that Filipinos were the intellectual and moral equals of their Spanish masters; he also worked for fundamental political and social reforms. These aims pervaded his writing, most of which was done in Europe, where, with one brief interruption, he resided between 1882 and 1892. His education, centring in medicine but extending to many fields, was acquired in the Philippines and Europe. His two novels, *Noli Me Tangere* (1886) and *El Filibusterismo* (1891), vividly pictured the evils of Spanish rule in the Philippines. In 1890 he published an annotated edition of Morgas' *Sucesos de las Islas Filipinas,* hoping to show that the Philippines had its own history before Spanish rule. He also wrote articles for *La Solidaridad,* a Filipino reformist periodical published in Spain.

Rizal returned to Manila in 1892 and founded a nationalist reformist society (Liga Filipina), with the result that the Spanish exiled him to Dapitan on northwest Mindanao (1892–96). When the Philippine revolution of 1896 began, Rizal, who was on his way (via Spain) to Cuba for medical service with the Spanish Army, did not take any direct part. He was, nevertheless, arrested aboard ship and brought back to Manila to stand trial for complicity in the insurrection. A military court found him guilty, and he was shot Dec. 30, 1896. His death enhanced his already great prestige among Filipinos and stimulated national sentiment.

See Rafael Palma, *The Pride of the Malay Race,* trans. by Roman Ozaeta (1949); Frank C. Laubach, *Rizal: Man and Martyr* (1936); W. Retana, *Vida y Escritos del Doctor José Rizal* (1907).

(E. C. Cn.)

RIZE, a town on the Black Sea coast and headquarters of the *il* (province) of Rize, Turkey, lies about 45 mi. E of Trabzon. Pop. (1960) 22,181. The commercial quarters are on the narrow strip of land around a small bay and the residential quarters are scattered on the surrounding steep slopes. With its mild climate and luxuriant vegetation Rize is one of the most attractive towns of the Black Sea coast. It is the centre of the Turkish tea industry.

Rize il (pop. [1960] 248,930) is rugged, densely forested, and very humid. The interior is occupied by high mountains and is economically unimportant, but the coastal strip produces a large variety of agricultural products, the principal being maize (corn), the staple food, tea, and citrus. The climate is exceptionally mild and humid with January average temperature at Rize 6.6° C (44° F) and annual average precipitation 100.4 in. (255 cm.). The most important cash crop is tea, which was established there in the 1930s. The first Turkish crop of tea was taken at Rize in 1939 and the industry has been successfully expanded.

ROADRUNNER, a slender bird, *Geococcyx californianus,* characteristic of the deserts of the United States and Mexico, that spends most of its life on the ground, running about in search of food. Averaging about 22 in. in length, about half

H. CHARLES LAUN FROM NATIONAL AUDUBON SOCIETY

ROADRUNNER (GEOCOCCYX CALIFORNIANUS)

of which is tail, this picturesque member of the cuckoo family is further distinguished by a fairly long bill, ragged brownish crest, heavily streaked brown and white upperparts, striped breast, buff belly, and white-tipped tail feathers. In flight the short wings show a white crescent.

The roadrunner runs swiftly, carrying its body in a horizontal position, and halts abruptly, raising its tail vertically. It darts about in this manner after lizards, small snakes, scorpions, small mammals, insects, ground-dwelling birds, and fruits and seeds. It kills and eats poisonous snakes, a habit that has given rise to considerable local folklore about its prowess. The saucerlike nest is built in a bush, low tree, or cactus and the four to nine white eggs are incubated for an unknown period. Probably two broods are reared annually. (R. S. Pr.)

ROADS AND HIGHWAYS. Though in principle the terms "roads" and "highways" are synonymous, in practice "highways" is used only for the more important thoroughfares. The term "road" is used in a narrow sense to denote routes of minor or local importance, but it also retains its broader meaning of any prepared route on land destined for the movement of goods and persons. The term "street," formerly of more general significance, now refers to roads lying within the limits of a municipality.

I. HISTORY

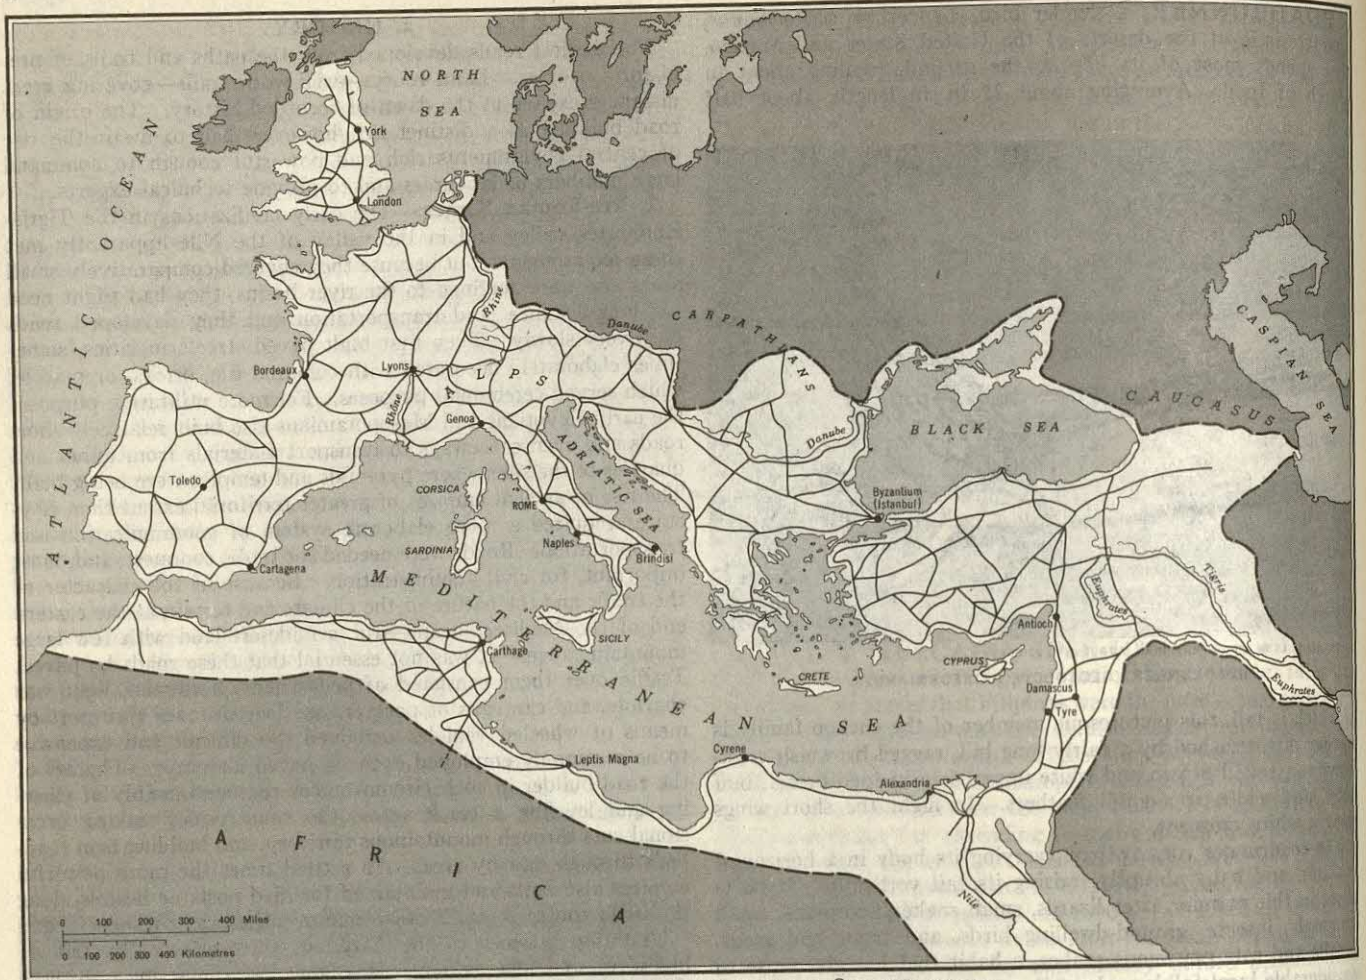
The earliest roads developed from the paths and trails of prehistoric peoples. Land routes—well-worn trails—covering great distances existed at the dawn of recorded history. The origin of road building as a distinct art, however, had to await the rise of central governments rich and powerful enough to command large numbers of labourers and to provide technical experts.

1. Pre-Roman Times.—The early civilizations in the Tigris-Euphrates valley and in the valley of the Nile apparently met these requirements, but because they covered comparatively small areas and were confined to the river basins, they had slight need for long-distance land transportation and they developed roads only very slowly. They first built paved streets in cities, sometimes elaborately decorated with coloured tile, bricks, or marble, which served ceremonial purposes. For more utilitarian purposes the early Egyptians and Mesopotamians also built relatively short roads and even causeways to transport materials from mines and quarries to the sites where pyramids and temples were being built. The rise of ancient empires of greater territorial extent than city-states required a more elaborate system of communication and transportation. Roads were needed for trade, conquest, and, most important, for civil administration. Because of the character of the traffic and the nature of the climate and terrain at the eastern end of the Mediterranean—arid, semidesert land with few large mountain ranges—it was not essential that these roads be paved. Traffic over them consisted of pedestrians, horsemen, light war chariots, and caravans or pack trains; long-distance transport by means of wheeled vehicles remained too difficult and expensive to be commonly employed even on paved highways. The art of the road builder in such circumstances consisted mainly of clearing and leveling a track across the countryside, making occasional cuts through mountainous territory, and building firm roadbeds through marshy areas. In settled times the more powerful empires also built and maintained fortified posts or hostels along the main routes to facilitate communication and preserve order.

Tradition ascribes to the Assyrians the first such system of highways, but the evidence is vague and conflicting. By the time of the Persian expansion in the late 6th century B.C., however, several roads spanned the area east of the Mediterranean from Egypt and the Aegean Sea to the Persian Gulf and perhaps as far as the Indus River. The most famous was the so-called Royal Road described by the Greek historian Herodotus, who claimed to have traveled it himself. It connected Susa, the ancient capital of Persia, with Anatolia and the Aegean seaports, a distance of more than 1,500 mi. Royal messengers could traverse the entire course in nine days, about ten times as fast as the normal travel time of three months for such a distance. Between Babylon and Susa they averaged 100 mi. a day, a speed not surpassed in ordinary human travel until the 19th century.

2. Roman Roads.—The Romans were the greatest road builders of antiquity. Among the outstanding features of Roman roads were their straightness, solid foundations, cambered surfaces, and systematic arrangement. Lime and pozzolana (volcanic ash) cement were widely used to make concrete. The first of the great Roman roads, the Via Appia or Appian Way, was begun by the censor Appius Claudius Caecus in 312 B.C. It stretched southeast from Rome for a distance of 162 mi. Later administrators extended it to Brundisium (Brindisi), the port of embarkation for troops going to Greece and Asia Minor, and to Reggio, whence troops and traffic were ferried across to Sicily and ultimately to North Africa. By the end of the Punic Wars seven great roads led from, or to, Rome; together with their many branches and connecting roads they formed a comprehensive network, giving rise to the expression "all roads lead to Rome." (*See* Italy: *History.*)

As Roman armies expanded their conquests beyond Italy, Roman road builders followed. Indeed, in many instances the soldiers, assisted by slaves and prisoners of war, were themselves the road builders, and many of the later roads began as lines of military advance or frontiers. In 145 B.C. they began the Via Egnatia, an extension of the Appian Way across the Adriatic in Dalmatia and northern Greece; by 130 B.C. this road extended into



ADAPTED FROM C. DAREMBERG AND E. SAGLIO, "DICTIONNAIRE DES ANTIQUITÉS GRECQUES ET ROMAINES," VOL. 5, © LIBRAIRIE HACHETTE

EXTENT OF IMPERIAL ROMAN ROAD NETWORK

Asia Minor where it joined the former Persian Royal Road, rebuilt by the Romans, and linked with other roads built or rebuilt around the eastern end of the Mediterranean. After the conquest of Carthage the Romans also built in North Africa a highway system that eventually spanned the entire south shore of the Mediterranean. The road system in Roman Gaul centred on Lyons, which was reached from Italy by two principal Alpine passes. Four main roads extended from there to the Rhine, the channel ports, and Bordeaux, with a southern road down the Rhône Valley connecting with the coast road at Arles. In Britain the conquest took place in stages, and engineers designed roads accordingly: examples of originally military roads are Fosse Way and Stanegate, south of, and superseded by, Hadrian's Wall. However, the main road network came to radiate from London (*see* BRITAIN: *Roman Britain*). The road system of Spain differed from that of other Roman provinces: instead of radiating from a single centre such as Lyons, London, or Rome itself, the main roads followed the periphery of the peninsula; secondary roads were built later into the central plateaus.

At the height of the empire, in the 2nd century A.D., the Roman highway system consisted of more than 50,000 mi. of first-class roads. Planned for the imperial courier service and the rapid movement of troops, these were furnished with posting stations with relays of horses about every 10 mi. and with lodging places (*mansiones*) about every 25 mi. Solidly built, Roman roads took the direct line wherever possible, using piles and embankments over marshy ground and cuts and even tunnels in hilly or mountainous country. In addition, a network of lesser roads, amounting altogether to perhaps 200,000 mi., linked the smaller towns and rural areas with the main highways.

3. After the Fall of Rome.—The decline of road building in Rome coincided with the decline of Roman political power. New construction fell off markedly after A.D. 200, and by the 4th century Roman officials found it difficult even to maintain existing roads. Though laws passed in the late 4th and early 5th centuries called upon local landlords to provide maintenance (a sure sign of the decay of central authority), they had little effect. A long period of economic and technological stagnation set in, and, except in the immediate vicinity of the larger towns and cities and where bits of Roman pavement survived, the roads of the Middle Ages and early modern times were simple dirt tracks, narrow, rutted, and rough, dusty in dry weather and muddy in wet. Wheeled passenger vehicles were rarely seen on them until the 17th century. Passengers went on foot, on horseback, or in litters, according to their status; merchandise was carried by pack trains. Gradually wagons and coaches came into use, at first for the transport of goods and later for carrying passengers. It is likely that the effects of these heavy, iron-tired vehicles on the soft dirt surfaces had something to do with the deplorable state of the roads described by Daniel Defoe, Arthur Young, and other 18th-century travelers.

The latter half of the 18th and the early 19th century witnessed a brief revival in the art of road construction. The initiative came first in France where, as early as the 17th century, the great ministers of Henry IV and Louis XIV, Sully and Colbert, made determined efforts to improve the state of the French roads. These efforts achieved little, however, until the creation of the *École des Ponts et Chaussées* (School for Bridges and Roads) in 1747, the first professional engineering school in the world, following the establishment of a central administration for roads and bridges in 1716. The graduates of this school, as engineers of the state, built many miles of new and improved highways in France, but, as civil engineers, they did not succeed in raising the level of the art above that achieved by the Romans.

In Great Britain, meanwhile, the rapid growth of commerce and industry urgently required better and more extensive means of transportation. Canals received the first and major emphasis, but new and improved roadways also came into existence. In Britain, unlike France, private initiative supplied the means and the intellect, although the state cooperated by allowing canal and turnpike companies to exercise the right of eminent domain and the right to collect tolls. A number of self-taught engineers, three of whom are outstanding, contributed new ideas and techniques: John Metcalf, Thomas Telford, and J. L. McAdam. They all recognized the importance of proper drainage, and McAdam devised an inexpensive self-sealing pavement consisting of small stones, chips, or gravel that could be applied directly to the soil or subsoil of a properly drained roadbed. As a result of the economy of this method of construction it was widely copied, and such water-impervious roads today are still called "macadamized," even when the chips or stones are mixed or covered with oil or a bituminous substance.

4. Early American Roads.—The first American roads were the narrow Indian foot trails that crisscrossed the wilderness. Many of these trails followed the well-worn paths originally formed by the movements of deer, elk, or buffalo. Early American explorers and colonists used water routes whenever possible. In many cases, however, the narrow winding Indian trails offered the only course. These trails sought the high ground, which offered a dry route that was generally kept free of leaves and snow by the wind. Among the more important Indian trails were the Old Connecticut path, which traveled from the upper Hudson valley near Albany to Boston; the Iroquois trail, which followed the Mohawk Valley and terminated near Niagara Falls after crossing the area south of Lake Ontario; Nemacolin's path, which was named after a Delaware chief and led northwest from the upper Potomac to Pittsburgh; and the Warrior's path, through the Cumberland Gap and Kentucky to the falls of the Ohio River. A notable military road built by the British forces was Gen. Edward Braddock's road from Ft. Cumberland on the Potomac to the forks of the Ohio. In 1775 Daniel Boone widened the Warrior's path into the Wilderness Road. As colonists moved farther westward they followed the maps prepared by Lewis and Clark, Mackenzie, Frémont, Thompson, and others who used the Indian trails as paths to open the West.

Virginia's first highway law was passed in 1632, and in 1639 the general court of Massachusetts passed a comprehensive act which ordered each town to appoint two or three men who would be responsible for building highways "where they may be most convenient." The early roads and streets were relatively local in character and were often seas of mud or clouds of dust, depending on what the previous day's weather had been. The Conestoga wagon, which made its first appearance in Pennsylvania, was probably the most famous vehicle of this period; later models of it became known as the Western "prairie schooner."

Toward the end of the 18th century the increased demand for better roads stimulated the construction of many routes with private capital as turnpikes (toll roads). The first United States turnpike utilized existing roads to connect settlements in the Blue Ridge Mountains with Alexandria, Va. The first American macadamized road, the Lancaster turnpike, was completed in 1794. It ran between Lancaster, Pa., and Philadelphia.

As early as 1802 the federal government undertook to build a road from tidewater to the Ohio Valley; known as the Cumberland Road or National Road, it reached the Ohio at Wheeling, Va. (now W. Va.), in 1818, and by 1830 had been extended to Illinois. Meanwhile, to meet the rapidly growing demand for improved means of transportation (commonly called "internal improvements"), states, counties, and lesser units of government either built canals and roads on their own account or chartered private companies to build them. In the history of transportation the first three decades of the 19th century are known in America as the "canal and turnpike era."

The advent of steam railways later in the 1820s spelled the end of progress in road construction for almost three-quarters of a century. Turnpike companies went bankrupt and their roadways fell into disrepair. Road building became almost the exclusive concern of counties and municipalities. With the westward expansion of settlement and the growth of population, the mileage of roads gradually increased, reaching a total of about 2,000,000 mi. at the end of the century; but the roads were poorly constructed and maintained, and in many instances were no more than dirt tracks. Of the total mileage in the United States, less than 100 mi. were hard-surfaced with tar, asphalt, or brick; about 100,000 mi. were "improved"—that is, graded and drained, and occasionally surfaced with crushed stone or gravel. Many roads ended abruptly at state or even county lines; nothing resembling a "system" could be said to have existed at the national or even the state level. Throughout the world at the end of the 19th century the quality of roads was scarcely better than it had been 1,000 or even 2,000 years before.

II. MODERN HIGHWAYS

The first demands for better roads, both in Europe and the Western Hemisphere, came in the latter part of the 19th century from the devotees of a new invention, the bicycle. The cyclists were soon joined by the owners and users of a still newer invention, the automobile. It was for the automobile in its various forms—passenger cars, motor trucks, and buses—that modern systems of highways were built. In 1900 there were only 8,000 motor vehicles in the United States; by 1925 there were 20,000,000; and by the mid-1960s more than 86,000,000. Western Europe and other prosperous regions of the world did not lag far behind this phenomenal rate of increase. (*See* MOTORING; TRANSPORTATION.)

1. The First Phase.—The increase in automobile traffic required more roads and better road surfaces. When oil, tar, and asphalt surfaces were introduced early in the 20th century, they served mainly as coatings to allay dust; later they were used as binders to prevent "raveling" of gravel and macadamized surfaces. These surfaces served light automobile traffic well enough, but the rise of heavy truck transportation during and after World War I led to demands for more durable pavements. Three new methods of road surfacing evolved in the 19th century, though none became common until after 1900. The first of these was concrete, which was used in cities such as London in the early 19th century, spread across Europe, and was first used in the U.S. at Bellefontaine, O., in 1893. Bituminous surfacing (asphalt), which was adopted in Paris, was used in Switzerland and France about the middle of the century and in the U.S. by the end of the 1870s. Tar macadam, used in Britain in the mid-19th century, spread in the next 25 years to the U.S. and later to Australia. In the 20th century experiments with other surfaces and road-building materials, such as brick and bituminous concrete, took place. By the 1930s most main highways were surfaced with concrete or various bituminous mixtures.

Between 1920 and 1940 all countries with any appreciable automobile traffic undertook road-building projects on a scale previously without precedent. In many instances the new highways followed existing routes so that the total increase in road mileage was less than the construction activity would indicate. The main objective was to provide hard-surface roads between major centres of population and economic activity; by the end of the 1930s the achievement of this objective was in sight when the outbreak of World War II interrupted road construction in almost all countries. With the resumption of road building after the war the major effort again went into improvement of existing highways to repair wartime damage and deterioration and to accommodate the larger volume and higher speed of postwar traffic. As a result, the first phase of the modern highway period, which seemed to be drawing to a close in the 1930s, did not actually end until about 1950.

Nations with Communist governments have not reported data on road mileage, but the totals are not believed to be impressive. Private automobiles in such countries are rare, and it is known that the Soviet Union, to take the most important case, has placed major emphasis on railways for the movement of both goods and persons, with airways supplementing them. Some other coun-

tries that have been economically undeveloped and have been almost passed over by both the railway and automobile ages are now making extensive use of airways in their efforts to modernize and catch up economically with the rest of the world.

2. Express Highways.—The outstanding development of mid-20th-century highway history was the construction of controlled-access, divided highways, frequently called superhighways or throughways in the United States, and motorways (in contrast to all-purpose roads) in Britain. These highways feature two or more traffic lanes in each direction, with opposing traffic separated by a median strip of grass or shrubs; elimination of grade crossings; controlled entries and exits; and advanced designs eliminating steep grades, sharp curves, and other hazards and inconveniences to driving. Frequently they have been constructed over completely new routes, passing near but not through large centres of population, on more or less direct lines between desired termini. Their advantages include high speed; greater safety, comfort, and convenience for drivers and passengers; and lower vehicle operating costs. Many of these new express highways, especially in the United States, are toll roads, but that is an incidental, not an essential, feature.

In 1924 Italy began construction of toll motor highways or *autostrada* that soon totaled 320 mi. in length. Although these did not attain the standards of later express highways, they did incorporate the features of limited access and elimination of grade crossings. They were built and owned by private companies and paid for by tolls and advertising. The first true express highways, the *Autobahnen,* were built in Germany. Although the idea originated and plans were formulated between 1930 and 1932, a national network, the *Reichsautobahnen,* totaling 1,310 mi. by 1942, was built by the Nazi regime for both economic and military purposes. The only other European country to undertake construction of express highways before World War II was the Netherlands. In the United States the Pennsylvania Turnpike and the Merritt Parkway in Connecticut were completed shortly before the nation's entrance into the war in 1941.

After the war the express highway movement gained momentum, slowly at first because of financial difficulties and the urgency of postwar reconstruction, then more rapidly. By 1950 eight U.S. states had toll roads that met express highway standards and totaled more than 750 mi. After that date virtually every state constructed some express highway mileage on either a toll or toll-free basis. In Great Britain the Special Roads Act of 1949 provided for a network of about 700 mi. of new express highways. By the mid-1960s nearly 300 mi. were built, the most important being the London-Birmingham motorway (1959). The Nether-

PROPOSED "E" SYSTEM OF HIGHWAYS AND OTHER MAJOR ROADS IN EUROPE

lands resumed its construction program in 1946 and by 1960 had about 300 mi. of modern express highways, giving that country one of the greatest highway densities in the world. Belgium completed the Ostend-Brussels motorway in 1958 and its share of the Antwerp-Aachen *autoroute* in 1964. Motorways were also planned to connect all principal cities and border points. France built several short express highways or *autoroutes* in the 1950s to facilitate egress from its major cities, but, with governmental policy favouring rail travel, only 200 mi. had been built and 260 mi. were under construction by the mid-1960s. West Germany resumed construction of the *Autobahnen* in 1957, with three four-year plans for federal highways. In 1964 Italy completed the *Autostrade del Sole,* stretching almost 500 mi. from Milan to Naples. By the mid-1960s the six countries of the European Economic Community, together with Britain, Austria, and Switzerland, had completed 4,270 mi., half of which was in Germany and a quarter in Italy, with plans to triple this amount by 1970.

The most ambitious of all express highway systems was the National System of Interstate Highways of the United States. Recognizing the military value of highways as well as the need for a vast program of highway improvement, Congress authorized the project in 1944 but did not appropriate special funds for it until several years later. Originally limited to 40,000 mi. (subsequently extended to 41,000 mi.), the system incorporates existing express highways built to its specifications, whether toll or free; but by far the largest part results from new construction financed mainly by the federal government. In 1956 Congress authorized $25,000,000,000 of federal funds, approximately 90% of the total estimated cost, to be expended over a 12-year period. As of the mid-1960s the 41,000-mi. project was scheduled for completion in 1972 at a revised estimated cost of $47,000,000,000, of which the federal funding would be 90%. As its symbol the interstate system employs the U.S. shield with white lettering on a red and blue background.

3. International Highways.—International highways, insofar as they are anything more than simple continuations of roads across national borders, must rest on treaties or agreements. In 1950 all European countries except Ireland, Spain, the Soviet Union, and Bulgaria signed an agreement calling for a European highway network totaling about 26,000 mi. A number of specific routes were designated, some covering existing highways, others to be built anew. The system envisaged both express highways and all-purpose roads; to qualify for inclusion in the system all roads were to be built or rebuilt to minimum specifications for each type of road. They were to be marked with the letter *E* preceding their number, with white symbols on a green background.

In 1929 delegates to the Second Pan-American Highway Congress in Rio de Janeiro worked out a general plan for a road system spanning the entire length of the Western Hemisphere. Little progress was made until World War II when, working against difficult obstacles and under great pressure, U.S. Army engineers and civilian contractors cut a primitive but usable road, the Alaska Highway, through the wilderness from Dawson Creek, B.C., to Fairbanks, Alaska. In 1946 the Canadian government assumed control of the portions of the road on its territory, in accordance with the original agreement, and the road was later made suitable for tourist traffic. Another section of the Pan-American system, the Inter-American Highway from Laredo, Tex., to Panama, also benefited from U.S. engineering and financial aid during the war, but was not completed until the early 1960s. Mexico completed the portion of the road within its borders without outside assistance. *See* PAN-AMERICAN HIGHWAY.

III. HIGHWAY ADMINISTRATION AND FINANCE

With the exception of the Roman and a few other ancient empires, the administration and finance of roads and highways have usually, until the 20th century, been the responsibility of local authorities. In English common law, for example, the responsibility for roads rested on the parish; this tradition was taken over in the United States by county and township authorities, and similar conditions prevailed elsewhere. Usually a local official such as a manorial landlord, justice of the peace, or county commissioner had ultimate responsibility for the upkeep of roads, although in some cases this responsibility was delegated to a special highway commissioner or overseer. Most able-bodied men were liable for labour on the highways, which was in reality a special tax called the *corvée* or road tax; it varied according to time and place from a few days to several weeks of work each year. Under such circumstances, without specialized technical competence in either labour or direction, the deplorable state of roads throughout most of recorded history is small wonder. The tendency of modern times, however, especially in the 20th century, has been to create specialized authorities responsible for greater mileages of roadways, endowed with special sources of financing, and employing specialized engineers and other technically competent personnel.

Highway systems as a whole function under a set of national and local policies applied through various administrative arrangements. In the provision and conduct of highway transportation, the roadway is generally provided and maintained by government through some designated administrative highway agency. The vehicles, though generally produced by private industry and operated by millions of individual operators who set their own origins, destinations, and schedules, are subject to limitations imposed by a government agency. These include limitations on some vehicular features (*e.g.,* size and weight), general rules concerning the conduct of the use of the vehicles (*e.g.,* vehicle codes), and various controls on the use of the roads (*e.g.,* signs, signals, markings, speed limits).

The capabilities and productivity of a highway transportation system are affected in great measure by governmental policies. In particular, the layout of the road network, the design features built into the roads, the traffic controls, and the level of maintenance have an important influence on the cost, safety, use, and convenience of the system.

The role of the modern highway agency (department, ministry, commission, or office of roads), then, is more than the performance of the technical functions of design and construction of the physical highway projects, even though these are basic functions. It is concerned also with translating policy into action, with underwriting, to the extent that it can, the effectiveness of the highway transportation effort of the economy, with how the road systems affect various aspects of community functioning, and with coordinating the road activities under its jurisdiction with those of other highway agencies in the same region.

Because of the essential nature of the design and construction functions, especially in the periods of development of new roads or appreciable improvement of the road plant, the highway agencies have tended to be basically engineering organizations. However, the staffs of modern highway agencies also may include attorneys, economists, sociologists, scientists, right-of-way land appraisers, accountants, and public information officers. In a small agency concerned only with an established and limited road system, a few engineers and skilled operating personnel may serve to maintain an effective road plant.

Generally, the world's industrialized nations have in existence fairly extensive road networks, where the major emphasis is improvement in capacity or operating effectiveness of the system. While the construction effort and expenditure may be large, the addition to the total road system mileage may be relatively small. On the other hand, in regions or nations where economic development is just beginning, the basic problem is that of providing roads where none exist. Criteria concerning what routes to build and in what priority are derived from general social and economic development policies and decisions.

1. The United States.—After the partial and temporary involvement of the state and federal governments in highway administration and finance at the beginning of the 19th century, New Jersey was the first state to participate directly in the construction of roads, beginning in 1891. It established a department employing trained engineers who acted in an advisory capacity to county officials for improvement of road construction. The highway department developed plans and specifications, and inspected and supervised the construction, but contracts were let

by the counties and the roads remained subject to maintenance by the counties. As an inducement for the counties to seek state aid, funds were appropriated by the state legislature to pay one-third of the cost of road construction.

With minor modifications, the New Jersey principle of state aid was adopted by many other states. By 1900 six other states had similar laws, and by 1917 every state had some form of state aid for road construction. A major stimulus to the movement for state highway departments resulted from the 1916 act making federal funds available for highway construction under certain conditions, one of which was the existence of a state highway department to receive and disburse the funds. In time the relations between state highway departments and local officials changed, with the states taking greater and usually exclusive responsibility for certain highways, called state highways. Most states also assist counties and localities with local roads.

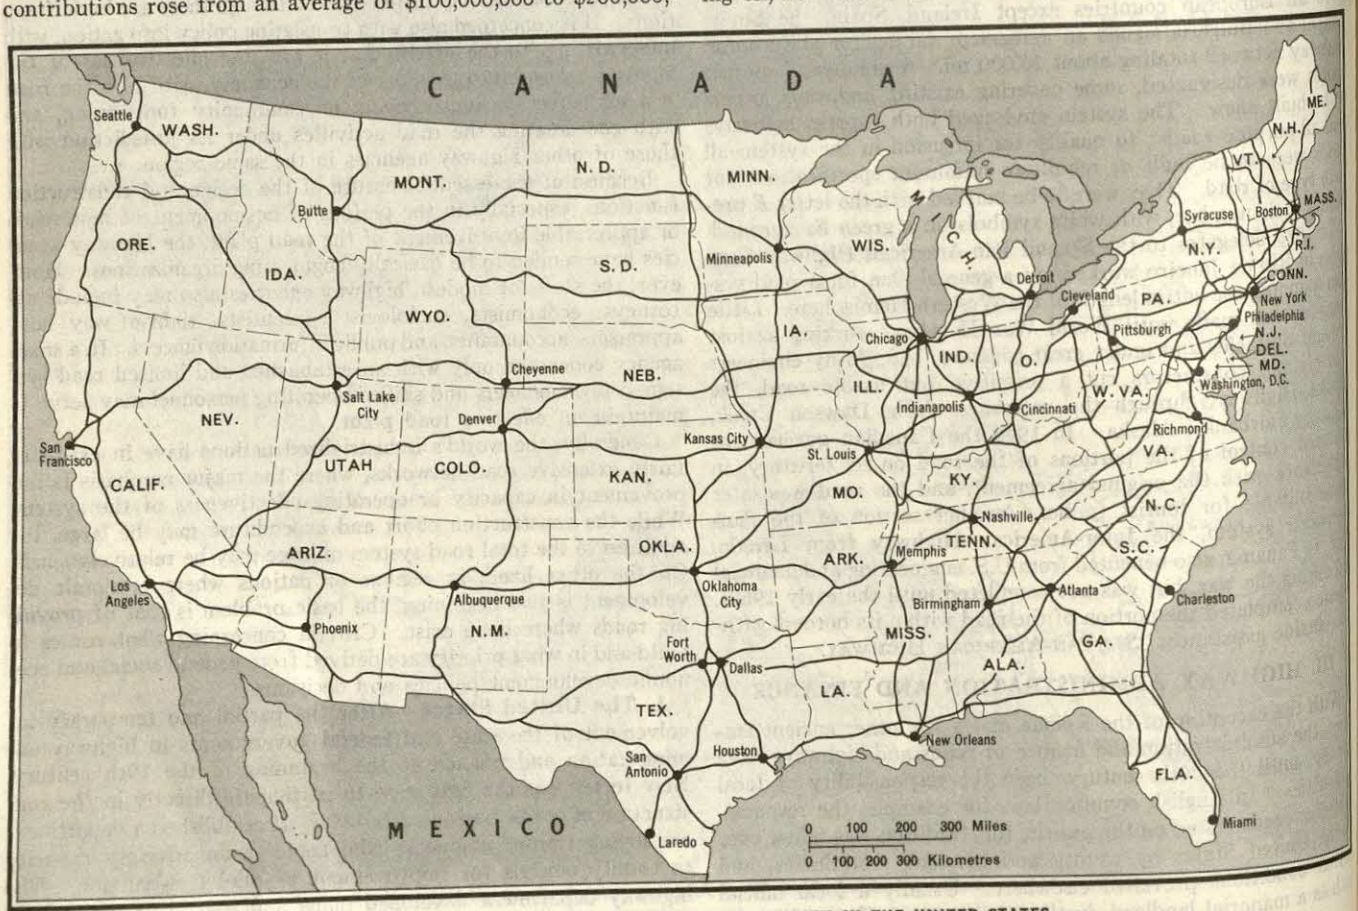
The federal government resumed its interest in highways (apart from military roads and national park and forest roads, which have always been a federal responsibility) in 1893 with the creation of the Office of Road Inquiry in the Department of Agriculture. Not until the Federal-Aid Highway Act of 1916, however, did Congress agree to share with the states the cost of construction of certain main roads. Under that legislation the states retain the initiative in choosing projects and carrying them out (subject to federal inspection) and also assume the costs of maintenance and policing. The federal-aid primary system, first designated in 1921, connects all principal cities, county seats, and other traffic-generating areas, and, in general, encompasses most of the nation's main roads. The Federal-Aid Highway Act of 1944 authorized the first funds for use in urban areas and created the federal-aid secondary system, designed to link feeder roads from smaller communities and farms to the primary system. Until the establishment of the Interstate System the federal government usually shared the costs of construction on a 50–50 basis, but in some cases (*e.g.*, for unemployment relief during the depression and for the elimination of railway crossings), it did not require any matching funds. Federal contributions rose from an average of $100,000,000 to $200,000,000 annually in the 1920s and 1930s to more than $3,000,000,000 annually in the 1960s. The mileage encompassed in the federal aid system rose from 179,000 in 1925 to 233,000 in 1945 to almost 1,000,000 in 1960.

The total road mileage in the United States in the early 1960s, including urban mileage, was approximately 3,500,000, of which more than 3,000,000 was in rural areas. Slightly more than two-thirds of the total was paved. About 650,000 mi. were under state control, and more than 2,300,000 mi. under county or local control. The federal government controlled directly about 100,000 mi. of park, forest, and military roads.

For many years property taxes and poll taxes were the only sources of road revenues. They were collected and expended by local governments. Commutation of taxes was permitted and "working off the road tax" was a familiar off-season occupation of farmers; it also helps to account for the poor state of roads in the 19th century. Prison labour and slave labour were also used by some states for road construction and maintenance.

The first motor vehicle fees levied by the states were small and were designed merely to cover the cost of registration, but the states soon recognized them as excellent methods of collecting highway taxes from those who used the highways. By 1915 the income from registration fees reached $18,000,000 per year, and by 1917 all states had motor-vehicle registration laws. Oregon, in 1919, was the first state to levy a special tax on gasoline for highway purposes. Within ten years all states had such taxes, and by 1930 they yielded approximately $500,000,000. In a few states local government units, especially cities, also collect taxes from highway users by means of registration fees and gasoline taxes. Early in the century expenditures on highways greatly exceeded income from taxes paid by highway users, and the difference was made up from general tax funds. Since that time, highway-user taxes have accounted for a larger and larger proportion of the expenditures on highways, and in some cases highway tax money has been diverted to nonhighway uses.

The federal government also collects taxes on gasoline, lubricating oil, new motor vehicles and parts, and tires and tubes. The



EXTENT OF PROPOSED INTERSTATE HIGHWAY SYSTEM IN THE UNITED STATES

Highway Revenue Act of 1956 established a highway trust fund into which go a group of specified (but not all) highway-related excise taxes and which became the sole source of funds for federal expenditures on the federal-aid highway systems. Thus, for the first time at the federal level, linkage was provided between highway-user imposts and highway expenditures. From the first federal grant for highways until 1952 Congress appropriated a total of $9,000,000,000 for this purpose; during the same period expenditures by all government units on streets and highways amounted to about $75,000,000,000 in terms of 1953 prices. During the early 1960s federal funds accounted for a substantially larger proportion of total highway expenditures, which for all government units was more than $12,000,000,000 annually.

2. Great Britain.—Before the Highway Act, 1835, responsibility for the repair of highways in England and Wales normally rested on the inhabitants of the parish in which the highway was situated. Roadwork was performed under the supervision of the justices of the peace in special highways sessions, through the two highway surveyors appointed annually for each parish. There were two important exceptions to parochial responsibility: certain streets in towns might be the responsibility of paving commissioners under local acts; and turnpike roads were repairable by the turnpike trustees under their private acts. The act of 1835 permitted the constitution of two other bodies which might become the authority for parochial highways, namely, elective highway boards and highway districts comprising two or more parishes. The act also provided that roads thereafter laid out should not become repairable by the inhabitants unless the procedure for their acceptance was complied with. This is the origin of the "private street."

The Highways and Locomotives (Amendment) Act, 1878, created a new class of roads called main roads, which included all roads which were no longer turnpikes after 1870 and other roads so declared by county quarter sessions; the county was made responsible for paying half the cost of maintaining these roads. Under the Local Government acts of 1888 and 1894, county councils became responsible for main roads and district councils for other roads. County borough councils became sole highway authorities in their respective areas. During the 20th century the central government assumed responsibility for certain roads that are main arteries of communication, known as trunk roads, and the Local Government Act, 1929, reallocated certain functions between local authorities. The highway authorities in 1965 were: (1) the minister of transport and civil aviation for trunk roads; (2) county borough councils for all roads in their areas other than trunk roads; (3) county councils for main roads, all roads in rural districts, and classified roads in noncounty boroughs and urban districts; and (4) noncounty borough and urban district councils for unclassified roads in their areas. The council of a noncounty borough or urban district having a population exceeding 20,000 was empowered to exercise the functions of repair and maintenance of any county road in its area. The minister could arrange with a highway authority to act as his agent in relation to any trunk road.

The Highway Act of 1959, the first consolidation measure since 1835, attempted to streamline the system by sweeping away more than 30 existing acts, some of which were 400 years old; but the committee responsible for the bill admitted that needed changes went beyond the scope of the new law and called for further legislation. Roads are designated as special roads or motorways, trunk roads, classified roads, and unclassified roads. The functions of each authority are not uniquely related to each type of road, however, and can be explained only by describing which authorities are responsible, and in what degree, for each type of road.

3. Other Countries.—After completion of the Alaska Highway during World War II, Canada built a road from the Peace River to Great Slave Lake in 1948. Two years later construction was begun on a 4,500-mi. trans-Canada highway. Work on this project continued throughout the 1950s and was nearing completion in the early 1960s.

During World War II Australia made a vigorous effort to fill some of the gaps in its road system by building roads that would connect strategic centres and thus be of military value. The 950-mi. Stuart Highway, for example, was built between Alice Springs (near the geographic centre of the continent) and the northern city of Darwin. The 875-mi. Queensland inland defense road was built to connect Ipswich in southern Queensland with Charters Towers in the north. After the war a lengthy legal battle developed between the state governments, which had large sums invested in railways, and those who advocated the construction of additional highways. Reasonable taxes and license requirements for the highway carriers were upheld by the courts in 1955, but prohibitory legislation was held unconstitutional. Most hard-surface roads in Australia are in the southern and eastern coastal regions near the cities of Melbourne, Sydney, and Brisbane.

Most nations with well-developed road systems classify their roads into two or three categories according to whether the controlling authority for each type is central, provincial, or local. France, for example, has its *routes nationales, routes départementales,* and *routes vicinales.* The tendency, however, is for the central authority to assume greater control and responsibility. In most countries motor vehicles, registrations, and fuel are taxed at much higher rates than in the United States; but the tax receipts are regarded as general revenue and do not necessarily return to the highway systems. Generally speaking, however, there is a greater awareness than in former years of the utility of a modern highway system, and more care and effort are being expended to that end in all countries. (Ro. Ca.)

IV. MODERN PLANNING AND DESIGN

1. Classes of Roads.—The routes that form a road network or system may be classified according to their principal function. Although they serve much short-haul traffic, the primary routes, or trunk-line highways, comprise the main routes that serve especially the through and long-distance movements of traffic and that interconnect the important centres of activity of a region or nation. When built to high standards and when lateral access to them is controlled to permit movement of large volumes of traffic safely at relatively high speeds, they are variously designated as expressways, throughways, freeways, motorways, etc. Although they comprise a relatively small percentage of the total network mileage, trunk-line routes carry a relatively large percentage of the total traffic.

A second class of roads (sometimes called the secondary system, collector-distributor system, or in rural areas farm-to-market roads) collects traffic from purely local roads and streets and feeds it to the trunk-line system; conversely, these routes distribute traffic from trunk-line routes to local neighbourhoods. The secondary system also provides routes for circulation within a local area.

A third class of roads serves a purely local land-access function; *e.g.,* a neighbourhood street that does not serve through traffic and a stub-end road that serves a few farms.

Although the combined road-street-highway network of a region serves vehicular movement as a whole, the functional systems may be constructed and operated by two or more agencies. Generally, the highest and most advanced prevailing standards of planning, design, and construction are incorporated into trunk-line systems, whereas secondary systems tend to reflect more or less conventional prevailing practice in a given region. Local-access roads may include excellent residential streets or the poorest dirt track to a remote mine.

2. The Highway Planning Process.—Through the planning process, the highway transportation needs of a nation, state, or community are translated into terms of the ruling features of a road system. It may be decided, for example, that a given trunk-line system shall serve cities of over 5,000 population and shall serve the principal needs for highway movements resulting from the economic activities (agriculture, natural resources development, industry) of selected regions.

Individual routes are planned, as well as the network of roads for the whole system. Further consideration is given to the way in which the location of a given route will relate to geographical features and to community layout and functioning. For exam-

ple, it may be decided that expressways shall, in general, bypass the central business districts of cities, avoid destruction of places of historic or cultural importance, and avoid splitting plots of land whose integrity must be preserved. Sometimes natural features such as stream crossings or mountain passes determine the routes.

A major endeavour in highway planning is estimating the magnitude, pattern, and other characteristics of the future traffic movements needed to serve the future economic and social activities of the area under consideration. From this estimated "demand" and through a knowledge of the performance (capacity, etc.) of types of highway facilities and components, the principal features of a route or system may be chosen. The location and arrangement of the route or routes also involve the relation of the highway, as a land user, to other land uses, since improved transportation facilities induce changes in land use. The methods of determining demand range from simple projections of traffic growth to very complex estimates of the size and distribution of future population and economic activity and the resulting pattern of movement.

3. Design Considerations.—The design process translates the outlines of the system envisioned in the planning process into a statement of the form and arrangement of the specific facilities and components to be constructed. Subject to agreed-upon design standards, the facilities are designed to meet requirements imposed by ambient physical conditions (terrain, soil conditions, climate, etc.), as well as the system requirements.

Types.—One type of design activity deals with fitting the roadway and its appurtenances into the natural and man-made terrain. This may be called locational design, for it involves route location and surveys, which are discussed more fully below.

A second type is geometrical design, which includes the dimensions, form, arrangement, and spatial interrelationships of the road elements that permit, control, or induce desired vehicular performance (*e.g.*, lane widths, clearances, and degrees of curvature). The designer must not only select pertinent forms of individual elements, but must arrange the combination and succession of elements to permit stated levels of traffic service and safe operation.

A third type of design has to do with the physical elements of the roadway; *i.e.*, devising the composition of materials, such as portland cement concrete or bituminous mixtures, and designing bridges, pavements, and other road elements. From a knowledge of the availability, properties, and costs of the materials, the design engineer must conceive and delineate the nature and composition of the roadway. The resulting assemblage of materials and structural elements must resist imposed forces and perform as specified over a chosen service life. A fourth type of design deals with devising operational subsystems such as lighting and traffic signals.

The design activities may also be considered with respect to the classes of features to be designed, including the alignment and cross-sectional features of the roadway itself, earthwork, pavements, bridges, drainage facilities, and roadside features. However, all design activities must be synthesized finally into a consistent overall design of the complete system.

Cost Considerations.—Throughout the design process, a basic consideration is cost. The criterion, however, is not necessarily the absolute minimum cost of each element, but an overall economy. For example, a stream crossing that would permit the lowest possible bridge cost may result in a circuitous routing of higher overall route and transportation costs than a more costly bridge at another location.

Cost estimates of new or improved facilities can be made after the general features of a system have been chosen and after some preliminary design. From these estimates, if a project is shown to be feasible, a financing plan can be developed and a construction program established. But to be practicable, the project must be both physically and financially feasible: physically, if it is attainable within the state of the art and if the requisite skills and materials are available for its design and construction, and financially, if the benefits to be derived from the facility exceed the costs.

Design Standards.—Design standards result in a more efficient design process and more consistent treatment. For vehicular operations, consistent treatment of geometrical design features promotes greater traffic safety, and the consistent treatment of physical design features tends to induce lower overall costs of construction.

Usually in each nation, and sometimes in a region or jurisdiction, professional agencies concerned with highway development establish design standards. In the U.S., the American Association of State Highway Officials develops nationwide standards for primary highways. When accepted, these standards become the criteria for design of the federal-aid highway systems and the other roads in most of the states. For example, the minimum "design" speeds specified for the interstate highway system in rural areas are: flat terrain, 70 mph; rolling terrain, 60 mph; mountainous terrain, 50 mph; and in urban areas, 50 mph. Higher values may be used by state highway departments under appropriate conditions. Requirements dealing with gradients, curvature, transition curves, superelevation, and sight distance are dependent on design speeds; *e.g.*, the gradients shall not be steeper than 3, 4, and 5% for design speeds of 70, 60, and 50 mph, respectively, except in very rugged terrain, where gradients 2% steeper may be used.

As a basis for designing features which affect the system's capacity to handle traffic volumes, the concept of the design hourly volume is used. For the interstate system this is specified to be the peak-hour traffic that is as high as the 30th highest hourly volume of two-direction mixed traffic estimated for the year 1975. (Portions of the interstate system designed after 1963 were planned to serve traffic growth estimated for 20 years, rather than to handle 1975 traffic.) The number of lanes, the use of median strips, the use and nature of grade separations, the arrangement of elements governed by sight distance, etc., are functions of the design hourly volume. Other features may be governed by the prevailing characteristics of the vehicles and consideration of safety, such as lane widths (12 ft.), shoulder widths (ordinarily not less than 10 ft.), and width of median strips. Because direct access to the traveled roadways of the interstate system is prevented, the service to adjacent property is provided by frontage or service roads designed as part of the route.

For other types of roads and systems, the design standards used by a road agency are adapted to the needs, conditions of use, and financial resources of the jurisdiction. The nature of the terrain and the general climatic conditions may have an important effect upon the physical design characteristics (and upon the construction and maintenance costs) of roads. Roads constructed in rugged mountainous terrain are more costly than roads built to the same design standards in relatively flat terrain with good soils for support. The design (and construction) practices that evolve and are used may differ considerably among regions having markedly different climatic conditions, such as the temperate climate of Western Europe, the tropical climate of West Africa or India, or the arid and semiarid climate of some regions of the southwest United States or Australia. Since the kinds of surface soils (in or on which the roads must be built) and the kinds of construction materials locally available are conditioned in the long term by prevailing climate, both costs and ways of dealing with the problems are affected.

Plans and Specifications.—The end result of the design process is a set of plans and specifications which spells out requirements that must be met for construction. The term "plans" in this context refers to drawings—graphic representations of the nature of the facility and its components.

4. Route Location and Route Surveys.—As a part of the planning-design process, or in close conjunction with it, a series of route location studies are made, leading to the final location of the roadway and its appurtenances. The "best" route is usually the most economical route within the limits of specified grade, curvature, and other design controls. In many instances, however, especially in urban areas, there may be other considerations, such as preservation of established land uses or buildings, which may override the conventional criterion of least cost of facility or even least total transport cost.

The route location process involves a series of surveys that provide the necessary information about the terrain through

which a projected route will pass. After a location has been selected, detailed design and cost estimates can be made and a basis provided for designating and acquiring land for right-of-way.

Three general stages in the route location process may be distinguished: a reconnaissance stage, a preliminary location stage, and a final location stage.

In the earlier days of road building, especially in new country, the process was largely a field operation. It was essentially design-in-the-field; the key man was the location engineer, or locator, a person with experience and skill. In some instances, after preliminary reconnaissance, with a kind of "second sight" of how the road could be fitted to the terrain, he might almost telescope the three above-mentioned stages into one operation.

Later, until about World War II, location surveys became more elaborate and detailed. From reconnaissance work came a strip map having sufficient information about topography and natural control points so that several general alternate locations could be studied and a preliminary line could be run for the selected route. This line was usually laid out with transit, tape, and level, providing distances, directions (angles), and a profile in elevation; often enough topography was mapped to give preliminary information for balancing earth-moving work in cuts and fills and for dealing with drainage problems. From these data a final location was selected and staked out; during the final location work, the curves were laid out and cross sections (profiles perpendicular to the line) were taken so that slope stakes could be set and estimates of earth-moving work could be prepared for construction purposes. Minor adjustments could also be made during the final ground location.

Since World War II, the use of aerial surveys and photogrammetric methods has revolutionized the road location process. While the three stages are still present, after key ground controls are established and aerial photographs taken, the work is largely "office oriented" until the final staking out takes place. From stereophotographs, maps of varying degrees of refinement are prepared. Small scale maps (and the photographs themselves) give information for reconnaissance not only on the shape of the ground surface but also on the nature of the terrain, the soils, the ground water conditions, and potential sources of road-making materials near the line of the road. From larger scale maps various trial alignments are studied in detail, and cross sections for earthwork computations are plotted.

The use of automatic stereoplotters and electronic data processing has greatly speeded up the process and also permitted the detailed study of a variety of locations. The use of aerial survey techniques has not only reduced the effort and increased the scope of the location process in rural areas where the natural topography is a key factor, but also has proved valuable in congested urban areas where buildings and other facilities make ground surveys extremely difficult.

After deciding the location of a facility and its appurtenances, land is acquired for right-of-way. A process of legal description, appraisal, negotiation for purchase or condemnation, and legal acquisition of title is involved. Although governments may exercise the powers of eminent domain, the procedure may vary among states and nations, depending upon their legal systems and the powers granted to the highway agency.

V. CONSTRUCTION

Most highway construction is performed by private companies under contract with the highway agency. In some jurisdictions where the amount of construction is small and ordinarily consists of minor reconstruction or replacement, the highway agency sometimes performs the work with its own forces.

The major construction operations include site clearance (*e.g.*, removing buildings and relocating utilities), grading operations (*e.g.*, excavating, hauling, embankment construction, shaping the roadway cross section, compacting earth in embankments and subgrades), construction of drainage structures, paving, construction of bridges and other structures, and in some instances work pertaining to roadside treatment (such as landscaping).

Construction supervision and control activities performed by the highway agencies include setting of line, grade, and cross sections; measurement of quantities used as a basis for payments to the contractor; and inspection to determine conformance to the plans and specifications with respect to dimensions, quality of materials, and location of various items (*e.g.*, culverts, abutments).

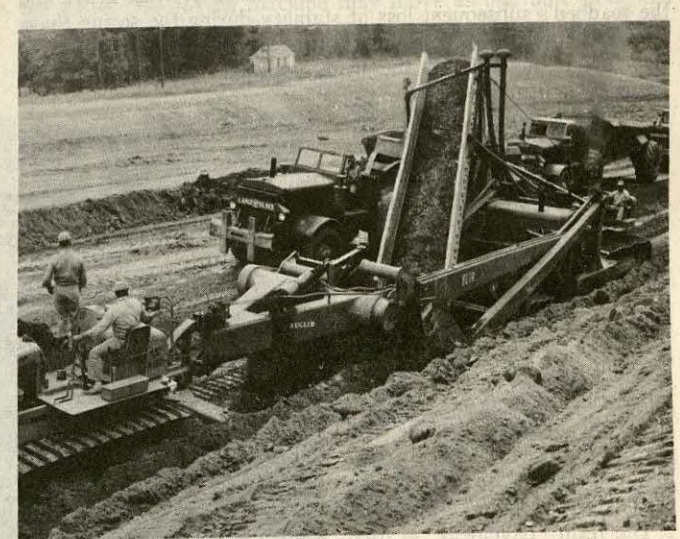
For large complex operations some contractors may have staff engineers who design various construction processes, devices, and temporary structures and who control the highly technical aspects of work.

Work scheduling and cost control are important aspects of the construction process. In the construction of new facilities on the alignments of existing routes, particularly routes carrying appreciable traffic, traffic handling requires considerable attention. The construction of temporary roadways, detours, and operation of traffic controls to maintain safe movement and minimize traffic delay calls for special design and scheduling.

1. Earthwork.—An important part of road building has to do with earth materials. The roadway as a whole must rest on soil or rock deposits of widely ranging composition and quality. Many primitive roads are composed of soil, and some better roads use soil and rock (usually treated or processed) to make up the lower portions of the composite pavement structure. To obtain desirable alignments and grades, cuts must be made in ridges and sidehills, and depressions must be filled. A fill or embankment is an earth structure that must be designed and constructed to have stability. Appropriate earth materials are selected and processed to provide sand, gravel, or crushed stone for building the road.

During recent decades, marked advance in the applied science called soil mechanics (*q.v.*) has contributed much to understanding soil behaviour and the technological control of soil for use in road building. The techniques for soil testing and classification provide a means for more precise identification of acceptable soil materials. Knowledge of soil strength and the factors controlling it has laid a better basis for analyzing and regulating the stability of soil masses subject to load. The evolution of techniques for compacting soils and controlling the density of compacted soils has put the design of embankments and other road components made of soil on a scientific basis.

The continued development since the 1920s of very large earth-moving equipment has revolutionized road construction. Not only has such equipment made practicable the handling of quantities of earth that would have been considered utterly unfeasible in an earlier day, but the relative cost of earth-moving has remained approximately the same for several decades, while the costs of other items of highway construction have appreciably increased. Two factors, the crawler tractor and the rugged heavy-duty engine, have enabled the development of very efficient and versatile



BY COURTESY OF EUCLID, DIVISION OF GENERAL MOTORS

REMOVAL OF LOOSE SOIL FROM A HIGHWAY SITE BY CRAWLER TRACTOR-DRAWN LOADER AND DUMP TRUCKS

construction equipment: for excavation, bulldozers (a tractor with a curved blade on the front for pushing and scraping), rippers, tractor-shovel units, scraper-carryalls; for hauling, the scraper-carryall, as well as very large heavy-duty trucks; for earth compaction, a family of compaction equipment (such as the sheepsfoot roller, heavy-duty pneumatic-tired rollers, vibratory compactors); and for grading and shaping the roadbed, various bladed graders, as well as the bulldozer. Belt loaders and belt conveyors, draglines, cranes, and heavy-duty power shovels are also used. (*See* EXCAVATION.)

2. Drainage.—There are two aspects to the problem of drainage—providing structures to care for surface water and avoiding the detrimental effects of water in the soils composing the roadbed.

Streams that cross the right-of-way are carried under the roadway by culverts (generally for smaller and intermittent streams) and bridges (for larger streams). The culvert or stream channel must be large enough to carry the flow of water at all times without damaging the roadway. The maximum runoff of storm water from the watershed that contributes to a stream is estimated, and a "design" flood flow is chosen, based on the most severe flood flow within the service life of the facility. In the case of bridges, the abutments and piers (if any) must be designed and constructed to avoid being washed out during high water.

Another phase of surface-water drainage is disposal of water falling on the roadway itself. Pavements are generally crowned or cambered (or otherwise sloped laterally) so as to carry water off to lateral ditches (or gutters), which in turn carry the flow to a stream (or a specially constructed drainage channel). Highways having an extensively paved area, particularly freeways in urban areas, present special problems in drainage.

The second major aspect of drainage concerns measures to avoid the accumulation of excessive water in the soil layers that compose the pavement structure, since the strength or supporting capacity of soil is decreased with increasing water content. Water may enter the base courses and subgrade by infiltration downward through the pavement surface (and shoulders) and by lateral inward percolation of water from alongside the roadway.

Of the three measures used to keep the roadbed from losing stability, the first is to provide and maintain as impervious a pavement surface as possible. In heavy-duty pavements, a primary purpose of joint sealing and seal coating is to prevent water infiltration. A second measure is to construct the roadbed sufficiently high above the water table—both the normal water table and the temporary fluctuating water table induced by water in the lateral ditches or standing alongside the road. A third measure is the use of roadbed soils that do not attract and hold appreciable water by capillary action. For this reason granular soils are preferred for base courses. Allied to the problem of the detrimental effect of water in the subgrade is the problem of frost heave and the roadbed's subsequent loss of stability during the spring thaw.

3. Pavements.—The primary function of a pavement as a structure is to transmit the loads imposed by vehicles to the basement soil under the roadway in such a manner that the soil mass remains stable (*i.e.*, it does not exhibit detrimental deformation or does not rupture). Moreover, the wearing surface of the pavement structure must resist the abrasive action of moving traffic and must provide acceptable riding qualities. The pavement structure and its components also must resist the deteriorating influences of temperature and moisture change and various induced chemical reactions; it must also protect the roadbed from water infiltration.

The term "pavement" is used in two senses: it refers to the top layer, which provides the riding surface, and to the layered system, comprising the wearing course, one or more base courses, and the subgrade, or natural basement soil. It is this layered system that must be dealt with in the structural design of a pavement. The action of each successive layer is to "spread the load" so that the underlying layer of weaker material can support the pressures transmitted to it from above.

Among the many types of pavement, two major categories may be distinguished: those built entirely of natural earth materials (soil, gravel, broken stone); and those in which the upper layers, at least, are made from manufactured materials such as asphaltic concrete or cement concrete and with permanent surfaces containing either bituminous materials or cement as a binder.

In the more densely populated countries of Western Europe and North America, all the main roads and most of the secondary roads have pavements with permanent surfaces. In contrast most of the roads in the developing countries of Africa and Asia have surfaces of earth or gravel.

Natural Earth Materials.—Roads made entirely from natural earth materials can be suitable for carrying light traffic up to about 300 vehicles per day. Sufficient mechanical stability to carry traffic loads is provided by gravelly or sandy soils or by crushed rock combined with a small proportion of clay or some other fine material to act as a binder. The temperate and cold regions of North America and Europe generally require gravelly or stony mixtures with very little clay binder, while in hotter, drier regions, finer sandy materials are also extensively used, along with a larger proportion of clay binder.

Such roads are usually dusty in dry weather and tend to become corrugated and develop potholes, while in wet weather they are often not sufficiently stable to carry heavy traffic. Deliquescent salts such as calcium chloride and gummy residues such as lignin-sulfonates are used to reduce dust and to help in binding the road surface in dry weather. Mineral oil and occasionally vegetable oils are also used. On all such roads regular maintenance is necessary to retain an even running surface, and the frequency and cost of this maintenance generally mounts rapidly as traffic increases.

Roads with Permanent Surfaces.—Such roads consist of layers of material laid on natural soil or a prepared subgrade, each successive layer being stronger than those below, the whole being surmounted by the running surface.

1. The subgrade is a natural soil on which the road is laid. This soil, which is either found on site or imported to form an embankment, must be compacted to improve its bearing capacity. In dry, warm regions the compacted subgrades are generally quite strong, while in wet, cool regions they may be very weak, particularly where the soils are clayey. An accurate assessment of the bearing capacity of the soil subgrade is important in considering the design of the road structure.

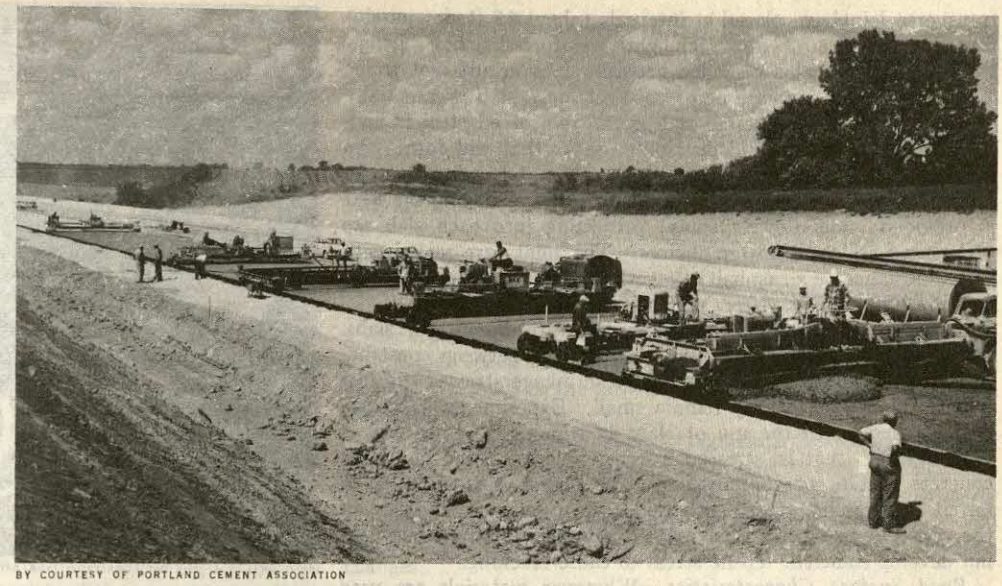
2. The subbase is the first layer of imported material to be laid on the natural soil. Besides its structural function, it frequently

BY COURTESY OF BARBER-GREENE CO.

ASPHALT FINISHER LAYING A BITUMINOUS MIXTURE

serves as a working platform on which transport vehicles and construction machinery can operate in building the road. The materials used to make subbases are frequently natural gravels, sandy soils, or broken rock. As with roads made from natural earth materials, high mechanical stability is sought by the careful selection of material and sometimes by combining different materials to produce a more stable mixture. The stability of these materials and their resistance to the weakening effects of water may be improved by an additive such as portland cement, lime, or a bituminous material.

3. For the base and surfacing, two forms of construction may be distinguished: flexible construction, in which bituminous binders are employed at least in the upper layers; and rigid construction, in which the functions of base and surfacing are combined in one material, portland cement concrete.



BY COURTESY OF PORTLAND CEMENT ASSOCIATION

CONVENTIONAL CONCRETE PAVING TRAIN USING SIX SEPARATE MACHINES THAT RIDE ON METAL SIDE FORMS DOUBLING AS RAILS

In flexible construction the lower layers of the base may be of natural gravel or crushed stone; natural materials stabilized with cement or lime also may be used. The upper layers and the surfacing are invariably made with bituminous mixtures. On very heavily traveled roads in Europe and the U.S. there is a growing tendency to employ bituminous mixtures for most or even all the layers of the base and surfacing. In contrast, on more lightly traveled roads, particularly in the warmer parts of the world, the road base may consist entirely of natural gravel, broken rock, or soil stabilized with portland cement or lime, with a surfacing that consists only of a thin bituminous treatment.

The design of the road structure can thus be a complex problem requiring considerable engineering skill to produce a road that is, on the one hand, economically feasible and, on the other, strong enough to carry the expected traffic load.

This design process involves the following principal steps: (1) traffic analysis to establish the combination of load, critical wheel load, and repetitions of load to which the pavement structure will be subjected; (2) evaluation of subgrade, subbase, and base materials to determine their load-bearing characteristics; (3) investigation of alternate combinations of base course and surface course (including types) that could meet requirements for load and durability under prevailing climatic conditions; (4) economic analysis of the several feasible designs; and (5) final selection of the optimum design.

Thus while a relatively lightly traveled road in a dry region may consist of a total thickness of 6 in. of relatively cheap base and surfacing, a heavily traveled road in a more humid region may require a total thickness of construction of 20 to 30 in., with the upper layers, at least, consisting of processed materials of relatively high cost.

Bituminous Mixtures.—Two types of materials are used in making bituminous mixtures: asphalts and tars. The tars used are the residues derived from the destructive distillation of coal. Some asphalts occur naturally (*e.g.,* Trinidad asphalt), but most of the asphalts used are residues derived from the petroleum refining process.

The combination of bituminous materials with mineral aggregates, used in a variety of maximum sizes, gradings, and shapes of particle, results in numerous types of mixtures. These are designed for various uses and are adapted to various methods of processing in the field. Mixtures are designed to meet requirements such as stability, durability, effectiveness in preventing water infiltration, wearing resistance, skid resistance, etc.

Mixtures containing the harder grades of asphalt are generally processed in a "hot-mix" plant, where the final temperature reaches about 275° F (135° C). Mixtures containing the more fluid asphalts may be road-mixed or plant-mixed at atmospheric temperatures. The mixtures are spread and rolled into place with appropriate field equipment.

The mixtures (often called asphaltic concretes) used for heavy-duty bituminous pavements are generally composed of a densely graded, high-quality aggregate combined with a hard grade of asphalt, mixed in a "hot-plant," and placed by paving machines designed to produce a uniform surface having good riding qualities.

Portland Cement Concrete Pavements.—Concrete pavements are composed of portland cement and graded mineral aggregates; these materials are mixed with water, placed, cured, and allowed to harden to produce slabs having considerable flexural strength. They are often called rigid pavements because they tend to distribute the applied loads through slab action. (*See* CEMENT.)

A concrete mixture is proportioned to give specified strength, impermeability, and durability (*see* CONCRETE). It may be mixed on site or in a central mixing plant, from which it is hauled to the construction site in special trucks. In some instances the mixing process may be carried out during hauling in specially designed "transit-mixer" trucks. When mixing is done on the job, the mixer and paving machine may move as one unit along the roadway being paved. The placement of concrete requires the use of side forms usually placed so as to pave one traffic lane at a time. The freshly deposited concrete is compacted in place, usually by vibrators operated in conjunction with the paving machine. Following placement, a process of screeding (to obtain the shape and elevation of the surface) and finishing (to obtain the desired surface texture) is carried out. The freshly placed concrete must be cured in the presence of moisture for an appropriate period to attain the desired strength.

Vehicle loads produce flexural stresses in a pavement slab that may be critical at one of three locations: near a corner, near an edge, or near the centre of the slab. Also, fluctuations in temperature and moisture content of the slab produce differential tensile and compressive stresses across its thickness that result in "curling," and variations in resistance of the supporting layers may produce warping. The slab thickness, then, depends on the magnitude and frequency of the applied loads and induced stresses over the service life of the pavements, the resistance provided by the supporting base and subgrade, and the strength of the concrete.

Because of volume changes due to temperature and moisture change, the tendency of the concrete slab to expand and contract as a whole must be controlled. In one commonly used method,

transverse joints are placed at intervals (about 15 ft. for unreinforced slabs and 30 to 60 ft. for lightly reinforced slabs). Longitudinal joints are also provided between slabs in adjacent traffic lanes. Although in this type of construction a slab is essentially designed as a plain concrete slab, some reinforced steel is generally used to control and distribute cracks that will form. To avoid faulting of adjacent slabs, some plan of keeping them in alignment and of transferring the load from one slab to the next is provided; steel dowels (pins) projecting into each slab are often used as load-transfer devices. The joints are sealed with some substance (*e.g.*, asphalt) that will permit expansion and contraction but prevent water infiltration.

Some use is made of continuous reinforced concrete slabs. These slabs may be several hundred feet long between construction joints. The steel serves to carry shrinkage stresses and distribute the cracks so they remain small. Experiments have also been carried on in the use of slabs in which the reinforcing is "prestressed," that is, stressed in tension so as to induce in the concrete a state of compression. The object is to provide an initial compressive stress such that the subsequent tendency of the concrete to shrink relieves the compressive stress but does not develop sufficient tensile stress to cause cracking.

Road Surface Characteristics.—Whatever materials are used to make the running surface of the road, there are certain basic requirements in the interests of service and safety. The surface should be sufficiently plane and true to provide a safe and reasonably comfortable ride for road users. The almost universal use of machines for laying and finishing all types of surfacings makes it relatively easy to obtain high standards of riding quality both in new construction and in resurfacing projects.

A high resistance to skidding is required, particularly on high-speed roads, on the approaches to junctions, and at other places where emergency braking may be necessary. Normally all forms of road surfacing have an adequate resistance to skidding when they are clean and dry. The problem of skidding on wet roads has been intensively studied and has led both to improved tire and brake design and to a better understanding of what is required to provide road surfacing that will retain a good resistance to skidding under the polishing action of traffic. Basically a sharp "toothy" texture is required so that the tire can make effective contact with the road through a film of water. Also, on high-speed roads, a coarse, open texture is desirable to provide surface water with an easy path away from the points of contact between tire and road. For the first of these the choice of stone in the surfacing is particularly important, selecting those types that continue to present a rough surface under the abrasive action of traffic. The coarse texture required on high-speed roads is secured with bituminous materials by the design of the mixture and with concrete by finishing treatments at the time of construction.

The well-tried treatment for icy roads is the application of grit and salt. Where the hazard from icy roads is particularly high, electrical heating is sometimes employed, using metal grids built into the road surface that are automatically controlled.

A further requirement for road surfacings is that their surface texture should aid visibility at night. A relatively fine surface texture is required in towns and cities where the main illumination comes from street lighting, while on the open road, where only vehicle headlights are used, a relatively coarse texture is preferred.

4. Junctions and Interchanges.—An important consideration in the satisfactory functioning of a road network is the arrangement and layout of the junctions. A poorly designed junction is an obstruction to traffic flow and a source of accidents.

The treatment of a junction depends upon the volume of traffic to be handled and the design speed to be adopted. To handle traffic as safely and expeditiously as possible at junctions of conventional roads, traffic control measures are often applied (*e.g.*, restricted speed zones, lane markings, "yield" signs, and traffic signals). Also, roadside treatment may be required to provide adequate sight distance for traffic in the intersecting legs of a junction. At the junctions of modern, high-speed freeways or motorways the grade crossing of intersecting streams of traffic is eliminated by the use of grade-separation structures, often called "interchanges." The interchanges of very high-volume freeways (approximately 100,000 vehicles per day or more) may be extremely complicated, both in geometrical layout and structurally, and as many as four levels of the roadways have been used. Such interchanges may occupy several acres of land, and acceptable landscaping is an important consideration.

5. Bridges and Other Structures.—Both tunneling and the design and construction of bridges and other structures (*e.g.*, retaining walls) are specialized fields. Many highway agencies have a special division for structural design and construction supervision of structural work. (*See* also BRIDGES; TUNNEL.)

6. Roadside Treatment.—The land between the edges of the roadway and the right-of-way boundaries is important in building and operating modern highways, and, on limited-access facilities having separated roadways, the treatment of the median area between the roadways requires attention. The control of certain features on abutting lands (such as advertising signs, structures, and natural growth that affect sight distances) involves special legal problems; on controlled access facilities, access to road-user services (fuel, food, lodging) is necessary. On modern scenic highways or on long routes in sparsely settled regions, roadside rest areas with appurtenant facilities and services are often provided.

The way roadside features are designed and constructed affects maintenance costs, safety, the convenience and comfort of the road users, and the aesthetic sense of both road users and the sur-

rounding community. In some instances, roadside treatments are designed to shield adjacent land users from traffic noise.

VI. MAINTENANCE AND OPERATION

Maintenance, in a broad sense, refers to the activities involved in keeping the physical road plant (roadway, roadside, structures, and other appurtenances) in a state of satisfactory repair and in the operation of those facilities and services necessary to provide continuous, safe, and satisfactory traffic service. The phrase "maintenance and operation," then, includes much more than repairing pavements and cleaning ditches.

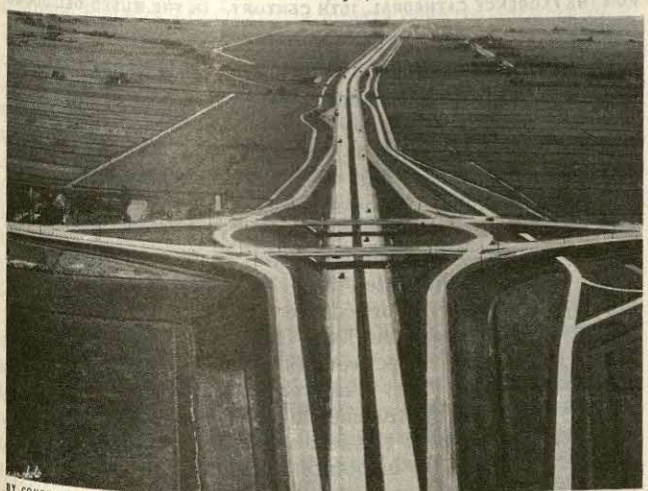
Since the quality of a highway's original design and construction influences its subsequent maintenance and cost, no fixed formula can be given for the proportion of highway expenditures that should be devoted to maintenance. In contrast with construction, where most of the work is performed by contract, most maintenance is performed by the highway agencies. Some separate items of maintenance work, however, are sometimes done by contract (*e.g.,* bridge painting).

Major physical maintenance activities include keeping the road surface and roadside area in satisfactory condition, maintaining drainage facilities, repairing storm damage, removing debris and litter, and maintaining traffic control facilities.

A substantial fraction of the maintenance effort is expended on the upkeep of the roadway surface. Gravel roads require intermittent blading and shaping and occasional resurfacing. Intermediate-type surfaced roads require patching and sealing, whereas high-type pavements require replacement or reconditioning of distressed areas and sealing. When a road surface wears too smooth, various surface treatments help to improve skid resistance.

Many devices and operational plans are employed to facilitate traffic service and induce safe vehicular operation. The design of many of these features is generally the responsibility of the traffic engineering section of a highway agency, but their operation and upkeep is usually a function of the maintenance forces.

To guide the movement of vehicles on the pavement and induce orderly flow, center line and lane markings and in some cases raised median strips and islands are used. In steep terrain and on curves where careless drivers may run off the roadway, guardrails are necessary; on dual roadways, when it is difficult to provide an adequate width of median separations, guardrails are also used, some of special design.



BY COURTESY OF INTERNATIONAL ROAD FEDERATION

INTERSECTION OF THE AMSTERDAM-UTRECHT HIGHWAY WITH A LOCAL ROAD WHICH BYPASSES AMSTERDAM

To mark roadway edges and warn of objects that restrict lateral clearance (such as culvert headwalls and minor road entrances), roadside markers of various design are employed; frequently these are of some reflecting material (*e.g.,* "cat's-eyes").

Signs perform three main functions: regulatory, warning, and informational. Speed-zone signs and stop signs are common examples of regulatory signs. Warning signs are those that call attention to hazards such as steeper grades and sharper curves than usual on the route; on modern high-speed roads, signs that can be exhibited when needed to warn of temporary hazards, such as fog or the presence of obstructions due to maintenance or construction work, are important. Included in the informational group are route markers and signs that indicate distances and turnoffs to destinations.

For positive traffic control, especially at intersections, traffic signals are used. Some intersection traffic signals are set to operate on a fixed cycle, and some are operated in coordination with preceding and succeeding signals to promote the continuous flow of traffic. In urban networks considerable experimentation has been carried on to develop area traffic-control systems; in such systems, sensor devices feed information on changing traffic flows into a high-speed electronic computer; its output schedules the settings of signals in the network to keep the network flow at an optimum.

While costly, the provision of nighttime illumination reduces accidents. Although continuous lighting of streets and highways is feasible mainly in urban areas, sufficient illumination, especially at intersections, is especially important. On major freeways, even in rural areas, there has been increasing use of lighting at interchanges.

ROANNE, a town of east-central France and headquarters of an *arrondissement* in the *département* of Loire, lies on the Loire River 55 mi. (88 km.) NW of Lyons by road. Pop. (1962) 51,468. Of ancient remains only the castle dungeon is left. The centre of the town is the Carrefour Helvétique. The *lycée* Jean Puy occupies the former 17th-century Jesuit college. The Joseph Déchelette Museum has a fine regional archaeological collection. A bridge over the Loire leads to the suburb of Le Coteau. The town is a junction of railway lines to Paris, Saint-Étienne, and Lyons (via Tarare), and of roads to Lyons, Saint-Étienne, Vichy, and Mâcon. Its situation made Roanne an important commercial centre, and it was later industrialized. It has weaving of cotton goods, spinning of artificial silk, knitting, tanning, mechanical and construction engineering, and the manufacture of hacksaws.

Roanne was a settlement of the Segusiani, known as Rodumna; it was a centre of crossroads in Gallo-Roman times, and was mentioned in ancient geography by Ptolemy. It was made a lordship by Jacques Coeur in 1443. (G. FR.)

ROANOKE, a city of western Virginia, U.S., on the Roanoke river, 166 mi. WSW of Richmond. It was settled in 1740 but did not become important until 1882 despite its favourable location in a fertile bowl between the Blue Ridge and Allegheny mountains, easily accessible from the north, east and west. It was first called Big Lick because of its salt deposits. In 1852 it became a way station of the railroad extending across southern Virginia but in 1880 it had only 669 inhabitants. Its growth started in 1882 when a railroad from the north made a junction there with the line across southern Virginia, offering an outlet for the coal deposits of the Virginias; the town acquired huge railroad shops and offices, and in that year was renamed Roanoke. In 1884 it was chartered as a city, its population at that time being 5,000. Railroads were supplemented by various industrial activi-

ties including fabricated steel. The city grew to 21,495 by 1900. Further growth was assured by the coming of the Virginian railroad in 1908 and of a large rayon plant in 1917. Roanoke suffered a labour depression after 1957 when the Norfolk and Western Railway shifted from steam to diesel locomotives and the rayon works closed because its product was outmoded. But the city's industry was too extensive for its prosperity to be halted permanently. Its truck lines expanded and hotel accommodations were provided for tourists from the Sky Line drive and the Blue Ridge parkway. The population of the city in 1960 was 97,110; that of the standard metropolitan statistical area (Roanoke city and Roanoke county) was 158,803. (For comparative population figures *see* table in VIRGINIA: *Population.*) Roanoke has a council-manager form of government, in effect since 1918. A few miles west of the city is Salem, the county seat and home of Roanoke college (Lutheran, founded 1842), and 6 mi. N. is Hollins, a private college for women, established in 1842. (F. B. S.)

ROANOKE ISLAND, in Dare county, off the coast of North Carolina, U.S., is south of Albemarle sound between the Outer Banks and the mainland. The island, which is 12 mi. long with an average width of about 3 mi., is the site of the first attempted English settlement in America and the birthplace of the first child of English parents born in the new world (Virginia Dare, Aug. 18, 1587). In 1584 captains Philip Amadas, or Amidas, and Arthur Barlowe there claimed the North American continent for Sir Walter Raleigh under his patent from Elizabeth I. After two months exploration they returned to England with two Indians, Manteo and Wanchese, and with samples of tobacco and potatoes. Next year Sir Richard Grenville (*q.v.*) transported 108 settlers under Ralph Lane, but the whole group returned to England with Sir Francis Drake in 1586. Two weeks later Grenville arrived with supplies, leaving 15 men to hold England's claim.

In 1587 John White, artist of the Lane colony (whose 75 Indian drawings are in the British museum) and grandfather of Virginia Dare, arrived at Roanoke Island but the 15 men had vanished. He planted a new colony comprising more than 100 settlers. Later he returned to England for supplies. Upon White's return in Aug. 1590, the only trace of this lost colony was the word "Croatoan" carved on one tree and "Cro" on another tree. Numerous and romantic are the conjectures as to the colony's fate. From 1937 its gallant story has been portrayed locally each summer by the outdoor drama, *The Lost Colony,* by Paul Green. The Fort Raleigh National Historic site was established in 1941 to restore this first English implantation, based on original excavations and employing authentic restorations.

Roanoke was the scene of a Civil War action in Dec. 1862 when Federal troops under Gen. Ambrose Everett Burnside took the island from the Confederates under Col. Henry M. Shaw.

Manteo, the county seat, and Wanchese, a fishing village, are added tourist attractions. (B. P. R.)

ROANOKE RIVER, of southeastern United States, rises in the Appalachian valley in southwestern Virginia and flows southeasterly in a 410-mi. long course into Albemarle sound, on the Atlantic coast of North Carolina. It drains an area of 9,580 sq.mi.

Shortly before crossing the Virginia-North Carolina state line it is joined by the Dan river, its principal tributary. The Roanoke is navigable for small craft for 112 mi. from its mouth to Weldon, N.C., which lies just below the fall line.

Ships with a draft of up to 12 ft. can reach Plymouth, N.C., 6 mi. above the mouth. In 1829 the Weldon canal, 12 mi. long, was opened to afford a passage around the falls, but it was abandoned in 1850. (F. O. A.)

ROBBER SYNOD, an irregular ecclesiastical council held at Ephesus in A.D. 449. *See* COUNCIL: *Councils to the 9th Century: From Ephesus (431) to Chalcedon (451).*

ROBBERY, in law, is the unlawful and forcible taking of goods or money from the person of another by violence or threatened violence. Robbery is larceny (*q.v.*) with violence. *See* also CRIME; CRIMINAL LAW.

ROBBIA, DELLA, the name of a celebrated family of Florentine sculptors, mainly associated with the production of works in enameled terra cotta. The principal members of this family were LUCA DELLA ROBBIA (*c.* 1399–1482), his nephew ANDREA (1435–1525) and two of Andrea's five sons, GIOVANNI (1469–1529?) and GIROLAMO (1488–1566).

LUCA, son of Simone di Marco della Robbia, matriculated in the guild of sculptors in 1432. He is mentioned in the preface to L. B. Alberti's *Della Pittura,* along with Filippo Brunelleschi, Masaccio, Donatello and Lorenzo Ghiberti, as one of the pioneers of Florentine Renaissance style, and he must have been an established artist by 1431, when his most important work was commissioned, the *cantoria,* or "singing gallery," over the door of the

ALINARI

PANEL OF THE "SINGING GALLERY," A BAS-RELIEF BY LUCA DELLA ROBBIA FOR THE FLORENCE CATHEDRAL, 15TH CENTURY. IN THE MUSEO DEL DUOMO, FLORENCE

north sacristy of the *duomo* ("cathedral"), on which he was engaged until 1438. The balance of evidence is that at this time he practised solely as a marble sculptor. In style Luca's marble sculptures recall the work of Nanni di Banco, to whom his early training may have been due. The *cantoria* (taken down in 1688 and now reassembled in the Museo dell'Opera del Duomo) consists of ten figurated reliefs, two at the ends of the gallery, four on the front and four beneath placed between the supporting consoles. The panels illustrate Psalm cl and show two groups of singing boys, trumpeters, choral dancers and children playing on the psaltery, cithara, organ and harp, tambourine and cymbals. Two bronze *putti* from the upper corners of the gallery are in the Musée Jacquemart-André, Paris. The architectural forms throughout are strongly influenced by Brunelleschi and the handling of the figures reveals a close study of classical originals. The panels owe their great popularity to the innocence and lack of artifice with which the children in them are portrayed.

Shortly before the completion of the *cantoria,* Luca received the commission (1437) for five reliefs of the arts and sciences for the campanile of the cathedral, in completion of the cycle begun by Andrea Pisano a century before, and in 1439 undertook work on the altars in the chapels of St. Peter and St. Paul in the cathedral. Two marble reliefs from the predella of the St. Peter altar survive in the Bargello. The most important of Luca's other works in marble are a tabernacle at Peretola, near Florence (carved for Sta. Maria Nuova in Florence in 1441–43), and the tomb of Benozzo Federighi, bishop of Fiesole (d. 1450), completed in 1459. In all these works Luca appears as an artist of strongly classical stamp, with a predilection for static figures and rectilinear compositions.

Both in the campanile reliefs (designed to blend with those of Andrea Pisano) and in the figures of the dead Christ, Virgin and St. John behind the Federighi monument, Luca's style represents a conscious reversion to the practice of the 14th century. The Federighi monument is surrounded by a strip of flat foliated decoration in enameled terra cotta. Intimately connected with these works is the bronze door of the north sacristy of the cathedral (1446–63). Undertaken in its early stages in collaboration with Michelozzo and the bronze sculptor Maso di Bartolommeo, the door consists of two wings, with heads of prophets in the frames and ten reliefs of the Virgin and Child, St. John the Baptist and the evangelists and doctors of the church. Though features of the design may be due to Michelozzo, it is likely that the whole figurated area is the work of Luca della Robbia.

The medium of polychrome enameled terra cotta appears for the first time in a dated work in the Peretola tabernacle, where it is used to set off the marble sculpture. The earliest documented work wholly executed in this medium is a lunette of the Resurrection over the door of the north sacristy of the cathedral (1442–45). According to Giorgio Vasari, the glaze with which Luca covered his terra-cotta sculptures consisted of a mixture of tin, litharge antimony and other minerals. Precedents are found in pottery and there is evidence that in the studio of Ghiberti experiments were made in carving terra-cotta sculptures with transparent glaze as a basis for gilding. In relation to sculpture, however, the technique adopted by Luca and developed by the later members of the Della Robbia workshop was a novel one. In the late 15th and 16th centuries works in this medium seem to have been regarded as an inexpensive substitute for marble sculpture, but analysis of the early commissions suggests that initially the medium was employed only in architectural contexts where marble sculpture would have been inapposite and that the function of the glaze was colouristic and not preservative. The resurrection lunette in the *duomo* was followed (1446–51) by a corresponding relief of the Ascension over the south sacristy door, in which a wider range of colour is employed.

Of the many decorative schemes for which enameled terra cotta was employed by Luca della Robbia, the most important are the roundels of Apostles in Brunelleschi's Pazzi chapel (soon after 1443); the roof of Michelozzo's chapel of the Crucifix in S. Miniato al Monte, Florence (1447–48); a lunette over the entrance of S. Domenico at Urbino (1450); two altars at Impruneta; and the ceiling of the chapel of the Cardinal of Portugal in S. Miniato al Monte (1461–66). Luca's last major work in this medium is an altarpiece in the Palazzo Vescovile at Pescia (after 1472). Many notable works by Luca della Robbia are found outside Italy. Among these may be mentioned the colossal stemma of René of Anjou and 12 roundels with the labours of the months from the Palazzo Medici in the Victoria and Albert museum, London; and the Altman and Demidoff Madonnas, respectively, in the Metropolitan museum, New York city, and the Museum of Art, Toledo, O.

After Luca's death at Florence on Feb. 20, 1482, his nephew ANDREA, who had been for many years an active member of his studio, assumed control of the Della Robbia workshop. Born on Oct. 20, 1435, Andrea appears, like his uncle, to have been trained as a marble sculptor. Neither in this medium nor in enameled terra cotta, however, was he an artist of Luca's calibre, and by the supremely high standard of Luca his work is trivial in form and deficient in sculptural quality. His best-known works are ten roundels of foundlings in swaddling clothes on the façade of the Ospedale degli Innocenti in Florence (about 1480). Andrea's interest in narrative sculpture led him to develop from the reliefs of Luca a class of large polychrome reliefs of which characteristic examples exist in Sta. Maria degli Angeli at Assisi, Sta. Maria degli Angeli at La Verna, S. Bernardino at L'Aquila, Sta. Chiara at Borgo San Seppolcro and Sta. Croce in Florence, as well as in many museums outside Italy. Between 1475 and 1522 the development of Andrea's style can be followed through a sequence of dated or documented works. Many of Andrea's smaller reliefs exist in a quantity of versions turned out from the Della Robbia studio.

Andrea della Robbia died at the age of 90 on Aug. 4, 1525, and control of the workshop passed to his son GIOVANNI (b. May 19, 1469). Giovanni's early works, of which the most remarkable are a lavabo in Sta. Maria Novella, Florence (1497), and the medallions in the Loggia di S. Paolo (1490–95), were executed in collaboration with or under the strong influence of his father, but as with age Andrea's grasp relaxed, Giovanni della Robbia evolved a coarser, more pictorial style in which the poverty of modeling and composition is accompanied by vivid, often vulgar polychromy. His most ambitious work is a frieze with representations of the works of mercy on the Ospedale del Ceppo at Pistoia (1525–29), in which he was assisted by his pupils Benedetto Buglioni (1461–1521) and Santi Buglioni (b. 1494).

Giovanni's younger brother GIROLAMO (b. March 9, 1488) was trained in Andrea's studio and collaborated with his father and brother until (about 1527–28) he moved to France, where he was employed on the terra-cotta decoration of the demolished Château de Madrid. After the death of Francis I (1547) Girolamo returned to Florence, but later (1559), on the appointment of F. Primaticcio as superintendent of the royal buildings, he resumed his work at the Château de Madrid and at Fontainebleau and was also employed on the monuments of François II and Catherine de Médicis at St. Denis. Girolamo della Robbia died in France on Aug. 4, 1566.

ROBBINS, FREDERICK CHAPMAN (1916–), U.S. pediatrician, shared with J. F. Enders and T. H. Weller (*qq.v.*) the Nobel Prize in Physiology and Medicine in 1954 for cultivation of the poliomyelitis virus in tissue culture. Robbins was born on Aug. 25, 1916, in Auburn, Ala., and attended the University of Missouri and Harvard Medical School (M.D., 1940). After two years at the Children's Hospital, Boston, Mass., he entered the army and became chief of the virus and rickettsial section, 15th medical general laboratory, stationed in the Mediterranean theatre, where he investigated epidemics of infectious hepatitis, typhus and Q fever. Following the war, Robbins completed his hospital training in pediatrics and joined Enders and Weller in 1948 in the research laboratory of the Children's Hospital, Boston. There they devised techniques for cultivating the virus of poliomyelitis in tissue culture which made possible the development of poliomyelitis vaccine, new diagnostic methods and the isolation of many new viruses. In 1952 Robbins became director of the department of pediatrics and contagious diseases, Cleveland Metropolitan General Hospital, and professor of pediatrics at Western Reserve University School of Medicine, Cleveland, O. (J. H. DE.)

ROBBINS, JEROME (1918–), U.S. dancer and choreographer, noted for the imaginative and original use of contemporary American themes in his ballets and for the excellent dances he devised for Broadway shows. A character dancer of distinction, Robbins appeared at the Gluck Sandor-Felicia Sorel dance centre, danced in musicals, and toured with Ballet Theatre before staging his first ballet, *Fancy Free*, in 1944. His ballets include *Interplay, Pied Piper* and *Fanfare*, and dances for the musicals *On the Town, The King and I*, and *West Side Story*. Robbins is associate artistic director of the New York City Ballet.

ROBERT OF COURTENAY (d. 1228), Latin emperor of Constantinople from 1221 to 1228, was a younger son of Peter of Courtenay (*q.v.*) and of Yolande, who, as sister of the former emperors Baldwin I and Henry, reigned in her own right in Constantinople until her death in September 1219. Their eldest son, Philip of Namur, renounced the succession in favour of Robert, a lazy and irresponsible youth, who arrived in Constantinople in 1221 and was crowned emperor on March 25. To secure his eastern frontiers he came to terms with the Greek emperor at Nicaea, Theodore I Lascaris, and was betrothed to Theodore's daughter, Eudocia. But Theodore died in 1222, and Robert fell foul of his successor, John III Vatatzes, with whom he concluded a humiliating treaty in 1225, having lost almost all the possessions of the

Latin Empire in Asia Minor. At the same time his European territories were overrun by the ruler of Epirus, Theodore Angelus, who captured Thessalonica and was crowned emperor there by 1228. Robert appealed to King Louis VIII of France; but in the end, after he had repudiated the princess Eudocia and seduced the daughter of a knight of Artois, his own barons turned against him. They broke into the palace, seized the lady, and cruelly mutilated her. Robert fled to Pope Gregory IX, but died in the Morea (Peloponnese) early in 1228 on his way back. His feeble reign marked the beginning of the end of the Latin Empire of Constantinople, which had been consolidated by his uncle, the emperor Henry.

See J. Longnon, *L'Empire latin de Constantinople* (1949). (D. M. N.)

ROBERT I (*c.* 865–923), king of France from 922 to 923, the younger son of Robert the Strong, faithfully served his more famous brother Eudes throughout the latter's reign (888–898). He inherited from Eudes (898) all the Robertian lands between the Seine and Loire rivers, but with other magnates swore fealty to the Carolingian Charles III the Simple. Nevertheless, he was already served in his domains by viscounts, officials usually regarded as instruments of regal power. From 911 onward, Robert's role became more decisive; his defeat of the Normans at Chartres in that year paved the way for the treaty of Saint-Clair-sur-Epte, by which Charles assigned to the Normans a specific territory. But dissension between Robert and Charles became undisguised after 919, and in 922 Robert and his son-in-law Rudolph (Raoul), duke of Burgundy, headed a revolt. They elected Robert king at Reims (June 29, 922) and he was crowned by Walter, archbishop of Sens. Charles, however, gathered an army in Lorraine, and in a battle fought near Soissons on June 15, 923, Robert was killed. His son was Hugh the Great, duke of the Franks, and his grandson, Hugh Capet.

See P. Lauer, *Robert I^er^ et Raoul de Bourgogne, rois de France* (1910). (J. De.)

ROBERT II LE PIEUX OR THE PIOUS (*c.* 970–1031), king of France, the son of Hugh Capet and Adelaide of Aquitaine, was born at Orléans and educated at Reims under Gerbert of Aurillac, later Pope Silvester II. Soon after his own coronation (July 987), Hugh arranged the election and coronation (December 987) of Robert, thus facilitating his eventual succession (October 996) as sole ruler. Robert's first marriage, with Rosala (or Susanna), daughter of Berengar I, margrave of Ivrea, and widow of Count Arnulf II of Flanders, lasted less than a year. He soon became attracted to Bertha, the wife of Eudes I (d. 995), count of Blois. Although their relationship was within the forbidden degrees and Robert was godfather to one of Bertha's children, he married her in 996. For this he was anathematized by Pope Gregory V. The accession of Gerbert to the papal throne in April 999 probably modified the situation; moreover, Robert had no children by Bertha and by September 1001 the couple had separated. Within two years Robert married Constance, daughter of William, marquis of Provence, by whom he had four sons and a daughter.

On the death without issue of Henry I (Eudes-Henry), duke of Burgundy, in 1002, Robert ousted a rival claimant and by 1015 had established control throughout the duchy. In his own domain he kept good order, but was less successful in quelling his greater feudatories, failing notably to prevent Eudes II, count of Blois and Chartres, from obtaining Sancerre (1015) and Champagne (1019, 1020, or *c.* 1023) and thus virtually encircling Robert's territory. A patron of the Cluniacs, Robert also gave considerable support to the *treuga Dei* (truce of God) movement.

Bouquet, *Recueil des historiens des Gaules et de la France,* vol. x (1760). *See* also E. Lavisse, *Histoire de France,* vol. ii, part ii (1901); C. Pfister, *Études sur le règne de Robert le Pieux* (1885).

ROBERT (1278–1343), king of Naples from 1309, of the Angevin dynasty, was born in 1278, the third son of the future Charles II (*q.v.*). The War of the Sicilian Vespers embittered his youth: when his grandfather, Charles I, died (1285), his father was a prisoner of the Aragonese; and under the Treaty of Canfranc (1288), which set his father free, Robert went as a hostage to the Aragonese court. The Treaty of Anagni (1295) enabled him to return to Naples. (*See* further NAPLES, KINGDOM OF; SICILIAN VESPERS.)

Robert's eldest brother, Charles Martel, died in 1295, leaving his claims to the Hungarian crown to his infant son Charles Robert (*see* CHARLES I, of Hungary); and the next eldest brother, Louis, became a Franciscan. Robert was therefore recognized by the pope as Charles II's heir, and took the title of duke of Calabria. In 1298 he married Yolande (Violante), sister of James II of Aragon. In 1299 he was sent with an army to coerce Frederick III (*q.v.*) of Sicily to accept the Treaty of Anagni. His successes led to the Treaty of Caltabellotta (1302). A widower in 1303, Robert in 1304 married Sancha, daughter of James II of Majorca.

Charles II's death (May 5, 1309) made Robert king. When the German king Henry VII launched his Italian expedition (1310), the Guelphs of Tuscany looked to Robert for help, but he sought Henry's friendship instead. Even so, Henry was about to attack the Kingdom of Naples when he died (August 1313).

When the Tuscan Guelphs appealed to him again, Robert sent help, but the Neapolitans and the Florentines were routed by the Ghibellines at Montecatini (1315). In the following years, however, Pope John XXII chose him to be the papacy's instrument against the Visconti (*q.v.*) of Milan. Several communes, most notably Genoa (1318), put themselves under Robert's protection; but numbers of them followed Florence in discarding his tutelage during Robert's sojourn (1319–24) in his countship of Provence.

Back in Naples, Robert reasserted himself in Tuscan affairs independently of Pope John. The Florentines, defeated by Castruccio Castracani degli Antelminelli (*q.v.*) in 1325, turned again to Robert. They appointed his son, Charles of Calabria, *signore* of the republic for ten years, but when Louis the Bavarian (*see* LOUIS IV, Holy Roman emperor) appeared in Italy, Charles deserted Florence; hastening to defend Naples, he suddenly died of malaria (Nov. 9, 1328). The disconsolate Robert's influence waned throughout communal Italy.

As the Sicilians disregarded the Treaty of Caltabellotta, Robert's forces had been vainly fighting since 1314 to win the island for the Angevins. With regard to the Neapolitan succession, Robert betrothed his infant heiress Joan (*q.v.*) to Andrew of Hungary, hoping to neutralize the claim of the Hungarian Angevins.

Robert died on Jan. 19, 1343, and was buried in Naples in the great church of Santa Chiara (built by Queen Sancha). He left a number of discourses and some theological, moral, and political treatises, as well as an essay on the poverty of Christ, which reflects Franciscan radicalism. Petrarch and Boccaccio (*q.v.*) extol him as a patron of literature, jurisprudence, and the arts.

See R. Caggese, *Roberto d'Angiò e i suoi tempi,* 2 vol. (1921–30); E. G. Léonard, *Les Angevins de Naples* (1954). (E. Po.)

ROBERT I, THE BRUCE (1274–1329), king of Scotland from 1306 to 1329, was a member of the Norman family of Bruce (*q.v.*) which had come to Scotland in the early 12th century. It was related by marriage to the royal family, and hence the sixth Robert de Bruce (d. 1295), grandfather of the future king, claimed the throne when it was left vacant on the death of Margaret ("the maid of Norway") in 1290. As a result, however, of the English king Edward I's judicial enquiry, it was awarded to John de Balliol (*q.v.*).

The eighth Robert de Bruce was born on July 11, 1274. His father, the seventh Robert de Bruce (d. 1304), resigned the title of earl of Carrick in his favour in 1292; but little is known of his career until 1306. In the confused period which followed the resignation of King John in 1296, he appears at one time among the supporters of William Wallace, but was later apparently restored to Edward's confidence. There is nothing at this period to suggest that he was later to be the Scottish leader in the War of Independence.

The decisive event was his murder of John ("the Red") Comyn in the Franciscan church at Dumfries on Feb. 10, 1306 (*see* COMYN, JOHN). Comyn, a nephew of John de Balliol, was a possible rival for the crown, and Bruce's actions suggest that he had already decided to seize the throne. He hastened to Scone and was crowned on March 25.

The new king's position was very difficult. Edward I, whose garrisons held many of the important castles in Scotland, regarded him as a traitor, and made every effort to crush a movement which he treated as a rebellion. King Robert was twice defeated in 1306, at Methven, near Perth, on June 19, and at Dalry, near Tyndrum, Perthshire, on Aug. 11. His wife and many of his supporters were captured, and three of his brothers executed. The king himself became a fugitive, hiding on the remote island of Rathlin off the north Irish coast.

In February 1307 he returned to Ayrshire. His main supporter at first was his only surviving brother Edward, but in the next few years he attracted a number of others, notably James Douglas ("the Good") and his own nephew Thomas Randolph, whom he created earl of Moray in 1312. The king himself defeated John Comyn, earl of Buchan, and, in 1313, captured Perth, which had been in the hands of an English garrison; but much of the fighting was done by his supporters. Edward Bruce conquered Galloway; Douglas recovered his own lands in Douglasdale, and occupied the forest of Selkirk and most of the eastern borders; in 1314 Randolph captured Edinburgh. During these years the king was helped by the support of some of the leading Scottish churchmen and also by the death of Edward I in 1307 and the ineptness of his successor Edward II. The test came in 1314 when a large English army attempted to relieve the garrison of Stirling. Its defeat at Bannockburn on June 24 marked the triumph of Robert I.

Almost the whole of the rest of the reign had passed before he had forced the English government to recognize his position. Berwick was captured in 1318; and there were repeated raids into the north of England, which inflicted great damage. Eventually, after the deposition of Edward II (1327), the government of Queen Isabella and Roger Mortimer decided to make peace by the treaty of Northampton (1328) on terms which included the recognition of Robert I's title as king of Scots and the abandonment of all English claims to overlordship.

The king's main energies in these years, however, were devoted to settling the affairs of his kingdom. Until the birth of the future King David II in 1324 he had no male heir, and two statutes, in 1315 and 1318, were concerned with the succession. In addition, a parliament in 1314 decreed that any who remained in the allegiance of the English should forfeit their lands: this provided the means to reward supporters, and there are many charters regranting the lands so forfeited. Sometimes, these grants proved dangerous, for the king's chief supporters became enormously powerful. James Douglas, knighted at Bannockburn, acquired important lands in the counties of Selkirk and Roxburgh, which became the nucleus of the later power of the Douglas family on the borders. Robert I also had to restart the processes of royal government, for administration had been more or less in abeyance since 1296. By the end of the reign the system of exchequer audits was again functioning, and to this period belongs the earliest surviving roll of the register of the great seal.

In the last years of his life, Robert I suffered from ill health, and spent most of his time at Cardross, Dumbartonshire, where he died on June 7, 1329, possibly of leprosy. His body was buried in Dunfermline Abbey; but the heart was removed on his instructions and taken by Sir James Douglas on a pilgrimage to the Holy Land. Douglas was killed on the way (1330), but, according to one tradition of uncertain value, the heart was recovered and brought back to Melrose Abbey.

In later times Robert I has come to be revered as one of the heroes of Scottish national sentiment. Many legends have gathered round his name, notably the famous tale of the spider, which was first given currency by Sir Walter Scott in his *Tales of a Grandfather*, 1st series (1828), where he describes it as a tradition in the Bruce family; though the same story had been told of Sir James Douglas by David Hume of Godscroft more than two centuries before in the manuscript version of his *History of the Houses of Douglas and Angus* (*see* Sir W. Fraser, *The Douglas Book*, 1885, volume i, pages 112–113). This posthumous and uncritical veneration has often obscured Robert I's true services to his country.

See also references under "Robert I, the Bruce" in the Index.

BIBLIOGRAPHY.—The most important original authority for the life of Robert I is the *Bruce*, a poem by John Barbour (*q.v.*), probably completed in 1376. The most recent edition is by W. M. Mackenzie (1909). *The Acts of the Parliaments of Scotland*, vol. i (1844), contains the materials for his parliaments, and over 90 of his charters can be found in *The Register of the Great Seal of Scotland, A.D. 1306–1424*, vol. i (1912). Many other charters survive elsewhere and can be found in the various publications of the Scottish historical clubs. The most recent life is G. W. S. Barrow, *Robert Bruce* (1964); Sir H. Maxwell, *Robert The Bruce* (1897), is of some value. *See* also W. Croft Dickinson, *Scotland from the Earliest Times to 1603* (1961).

(BR. W.)

ROBERT II (1316–1390), king of Scotland from 1371 to 1390, first king of the Stewart dynasty, the son of Walter, hereditary steward of Scotland, and Marjorie, daughter of Robert I the Bruce, was born on March 2, 1316. He may have commanded a division at the battle of Halidon Hill, fought against the English in July 1333, and was certainly a leader of resistance the next year, becoming joint regent with John Randolph, earl of Moray, for the exiled David II. Because of irresponsible conduct he was soon deposed, but was sole regent from 1338 until the king's return from France in 1341. Escaping from the defeat at Neville's Cross (1346), he was again regent during David's captivity (1346–57). Although created earl of Strathearn (November 1357), he constantly opposed the king, raising unsuccessful rebellion (1362–63) with the earls of Douglas and March, after which he was made to renew his oath of allegiance (May 1363). He opposed David's abortive scheme for cancellation of the royal ransom in return for making a son of Edward III heir to the Scottish throne, which would have nullified his own right of succession. He was later imprisoned (1368–69) in Lochleven Castle. On David's death (Feb. 22, 1371) he succeeded to the throne by hereditary right and as laid down by parliament in 1326. Throughout his reign he made little mark on affairs. In 1384 he gave over domestic administration to his eldest son, John, earl of Carrick (afterward Robert III), and in 1388, owing to Carrick's ill health, to his next surviving son Robert, earl of Fife. His first marriage (*c.* 1348) to Elizabeth Mure was solemnized after the birth of their four sons and five daughters, whose legitimation *per subsequens matrimonium* was of doubtful validity for succession to the crown. He married secondly in 1355 Euphemia Ross, the undoubted legitimacy of whose two sons (including Walter, earl of Atholl) and two daughters was one cause of the murder (1437) of James I (Robert III's son) at Atholl's instigation. He had also at least eight illegitimate sons. He died at Dundonald in Ayrshire on April 19, 1390, and was buried at Scone. (E. W.-M. B.-M.)

ROBERT III (*c.* 1337–1406), king of Scots from 1390 to 1406, was the eldest son of Robert II and Elizabeth Mure, legitimated through their marriage after his birth. In 1362–63 he joined his father in rebellion against David II, and in 1368 was imprisoned with his father and two brothers but was created earl of Carrick the same year. They were released in 1369. Robert II became king in 1371 and in 1384, owing to old age, devolved the domestic government on Carrick, but Carrick, when lamed by a horse of Douglas of Dalkeith, was supplanted by his brother Robert, earl of Fife, in 1388. On his accession on April 19, 1390, he changed his name to Robert (III) from John, which unhappily recalled John Balliol. Fife, created duke of Albany in 1398, continued to govern throughout this reign except during the years 1399–1402 when the king's dissolute heir, David, duke of Rothesay, took his place, until he met an early death in Albany's castle of Falkland. Robert III then sent his remaining son, James (afterward James I), to France for safe upbringing; but the news of his capture by the English proved fatal to the aging king, who died at Rothesay in Bute on April 4, 1406. He was buried in Paisley Abbey. He married (*c.* 1367) Annabella Drummond (d. 1401), by whom he had three sons and four daughters.

(E. W.-M. B.-M.)

ROBERT GUISCARD (d. 1085), duke of Apulia from 1059, a ruthless adventurer whose military and political genius revolutionized the history of southern Italy, was born in Normandy, the son of a petty feudatory, Tancred of Hauteville. From the first decades of the 11th century, Normans such as he had been going to southern Italy to exploit the troubled conditions there,

as Apulia was trying to free itself from the Byzantine empire while Campania was torn by the rivalry between the Lombard principalities of Capua and Salerno. Robert's eldest half brother William made his name as a leader against the Byzantine Greeks and was elected count of Apulia by his colleagues in 1042. Robert went out to join his second half brother Drogo, who in 1046 had succeeded William. Drogo, however, mistrusted the ambitious Robert and sent him to Calabria, where Normans hired by the prince of Salerno were attacking the Byzantines.

At the head of a predatory band, Robert used every resource of brigandage and deceit to carve out a dominion for himself in Calabria (hence his nickname Guiscard, "the Astute"); by 1060 he had ousted the Byzantines there. Meanwhile, he kept an eye on Apulia, the main Norman stronghold. When Pope Leo IX allied himself with the Byzantines against the Normans, Robert went to the help of his third half brother Humphrey, who had taken Drogo's place some time after the latter's assassination (1051); and he contributed substantially to the victory over Leo's army at Civitate in 1053. On Humphrey's death he seized the Apulian succession for himself (1057). Finally, under the Treaty of Melfi (August 1059), Pope Nicholas II legalized Robert's conquests, actual and future, by investing him as duke of Apulia, Calabria, and Sicily, while Robert acknowledged the papacy's feudal suzerainty over the lands in question.

To his youngest brother, Roger (*see* ROGER I), who had arrived to participate in his last Calabrian campaigns, Robert entrusted the task of conquering Sicily, helping him in the first stages (from 1060) and later sending reinforcements to him. Not satisfied with the territory assigned to him, Roger more than once took up arms against Robert, who eventually constituted Calabria and Sicily as a countship for Roger.

Robert's major achievement was the expansion of the little countship left by Humphrey into a duchy spreading from the Adriatic to the Tyrrhenian Sea. His conquest of Bari (1071) put an end to the Byzantine hold on southern Italy. In 1058, Robert married Sykelgaita (Sicelgaeta), sister of the prince of Salerno, Gisulf II, after repudiating his first wife, Alberada of Buonalbergo; but this did not prevent him from encroaching on Salernitan lands. Hostilities reached a climax with Robert's undertaking to defend the prosperous community of Amalfi against Gisulf (1073), and ended with his capture of Salerno (December 1076) and the surrender of Gisulf himself (summer 1077).

Vassals who rebelled against the new discipline of Robert's unitary state were energetically punished. His aggressions in upper Campania and in the Abruzzi, some of them against ecclesiastical lands, however, alarmed Pope Gregory VII (*q.v.*), who excommunicated him in 1074, but came to terms with him in 1080, as Robert's support was needed against the German king, Henry IV.

To forestall a Byzantine counterattack and also to avenge the deposed emperor, Michael VII Ducas (whose son Constantine had married one of Robert's daughters in an attempt at a Norman-Byzantine reconciliation), Robert in 1081 sailed with a considerable fleet across the Adriatic, seized Corfu, and besieged Dyrrachium (Durazzo; modern Durres). Though the Venetians inflicted heavy losses on his fleet, he took Dyrrachium (February 1082) and might then have marched across the Balkans had he not dutifully responded to Gregory VII's appeal for help in Rome against Henry IV. Affairs in Italy detained him throughout 1083, and in the spring of 1084 he had to march on Rome again to save Gregory, whom he took back to Salerno (his troops meanwhile had sacked Rome). Returning at last to the Adriatic operations, in which his son Bohemund was hard pressed, he took Corfu again in the winter and was besieging Cephalonia when he died, on July 17, 1085. He left Apulia to Roger, his son by Sykelgaita, preferring him to Alberada's son Bohemund.

See F. Chalandon, *Histoire de la domination normande en Italie . . .*, 2 vol. (1907); E. Pontieri, *Tra i Normanni nell'Italia meridionale*, vol. i, *La Conquista* (1948). (E. Po.)

ROBERT, the name of two dukes of Normandy.

ROBERT I (d. 1035), called the Magnificent or the Devil, was the younger son of Duke Richard II of Normandy and the father of William the Conqueror. On his father's death (1026 or 1027) he contested the duchy with his elder brother Richard III until the latter's opportune death one or two years later. A strong ruler, Robert successfully quelled his feudatories, and helped Baldwin IV, count of Flanders, to suppress a serious rebellion (1030). For support given to Henry I (*q.v.*), king of France, he received the Vexin Francais. When returning from a pilgrimage to Jerusalem, he died at Nicaea in July 1035.

ROBERT II (*c.* 1054–1134), nicknamed Curthose or Short Boots, was the eldest son of William the Conqueror. Although recognized in boyhood as his father's successor in Normandy, he twice rebelled (1077 or 1078 and *c.* 1082–83) and was in exile in Italy until he returned as duke on his father's death (September 1087). His next brother, King William II of England, invaded Normandy (1091) and Robert had to yield to him the counties of Eu and Aumale. William attacked again (1094), but peace was made so that Robert could take part in the First Crusade. He fought at Dorylaeum (July 1097), and was at the capture of Jerusalem (July 1099). His courageous leadership contributed to the victory at Ascalon (August 1099).

Robert was in Italy when his youngest brother Henry I succeeded William as king of England (August 1100). His invasion of England (1101) brought only an ignominious peace and Henry in his turn invaded Normandy (1105 and 1106). Captured at the battle of Tinchebrai (September 1106), Robert was kept prisoner for the remainder of his life, first at Wareham, Dorset, then at Devizes Castle; in 1126 he was transferred to Bristol and later to Cardiff, where he died, early in February (perhaps Feb. 3), 1134. His career, apparently one of unrelieved failure, was redeemed by his conduct on the crusade. His record in Normandy was lamentable; the administration of the duchy came virtually to a standstill and he made no sustained effort to control his turbulent vassals. His son, William Clito (*c.* 1102–28), was made count of Flanders (1127) by the French king Louis VI.

See H. Prentout, *Histoire de Guillaume le Conquérant* (1936); C. W. David, *Robert Curthose* (1920).

ROBERT THE STRONG (d. 866), count of various territories in the region of the Loire River, was ancestor of the Capetian kings of France. Details of his origin are scant and their interpretation much disputed, but by 852 he was serving the Carolingian Charles II the Bald as count in western Neustria and was *missus dominicus* in the west of the kingdom (853). But, resenting authority given on the Breton marches to Charles's son Louis (later Louis II), Robert joined the magnates' revolt (856). He was reconciled with Charles (861), becoming his most trusty warrior. When the Normans of the Loire threatened all the adjacent territory (862) and Louis was in rebellion, Robert, acting with Count Rannoux of Poitiers, fought several engagements and secured the neutrality of the Normans on the Seine. Charles sent him to Burgundy (864) to keep an eye on Girard, count of Vienne, but had to recall him to Neustria (July 865), where he won a great victory over the Normans. Granted full control in western Neustria (early 866), Robert was killed in battle against the Normans at Brissarthe (between Le Mans and Angers) in the autumn of 866 (possibly Sept. 15). His sons Eudes and Robert both became king.

See F. Lot, "Robert le fort," *Bibliothèque de l'école des chartes*, vol. lxxvi (1915). (J. De.)

ROBERT OF GLOUCESTER (fl. 1260–1300), English chronicler known only through his connection with the work which bears his name, probably written *c.* 1300. This is a vernacular history of England, from the days of the legendary Brut to the year 1270, written in rhymed couplets. The lines are of 14 syllables, with a break after the eighth syllable. In some manuscripts the early part (up to 1135) is followed by a brief continuation by an anonymous versifier, and in these slight deviations from the version generally accepted as Robert's are also discernible. The authorities employed for the earlier part were Geoffrey of Monmouth, Henry of Huntingdon, William of Malmesbury, the English chronicles and some minor sources; Robert, in making his recension of it, also used the *Brut* of Layamon. From 1135 to 1236 Robert is still a compiler, although references to oral tradition become more frequent as he approaches his own time. From 1256 to 1270 he

has the value of a contemporary authority, but he is more important to the philologist than to the historian.

Robert's chronicle was first edited by T. Hearne, 2 vol. (1724), but this text was superseded by that of W. Aldis Wright, 2 vol., Rolls series (1887). Extracts (1192–1270) were edited by F. Liebermann in *Monumenta Germaniae Historica, Scriptores,* xxviii, pp. 663–669 (1888).

Bibliography.—T. D. Hardy, *Descriptive Catalogue of Materials Relating to the History of Great Britain and Ireland,* 3 vol., i, pp. 25, 68, iii, pp. 181–189, 623 (1862–71); K. Brossman, *Über die Quellen der mittelenglischen Chronik des Robert von Gloucester* (1887); W. Ellmer, *Anglia,* x, pp. 1–37, 291–322 (1888); H. Strohmeyer, *Der Styl der Reimchronik Roberts von Gloucester* (1891), "Das Verhältnis der Handschriften der Reimchronik Roberts von Gloucester," *Archiv für das Studium der neueren Sprachen,* lxxxvii, pp. 217–232 (1891).

(X.; D. Wk.)

ROBERT of Jumièges (d. *c.* 1055), archbishop of Canterbury, was a Norman monk who became prior of St. Ouen and in 1037 abbot of the Benedictine abbey of Jumièges, near Rouen. He was taken to England by his friend Edward the Confessor in 1042 and made bishop of London in 1044. He became Edward's leading adviser and head of the Norman party, and was appointed archbishop of Canterbury in 1051. Although Robert was instrumental in bringing about the exile of Earl Godwin in 1051, on the native leader's return in 1052 the archbishop himself was forced to flee to the continent. Deposed and outlawed by the Witenagemot, Robert died at Jumièges, possibly in 1055. The uncanonical usurpation of the primatial see by Stigand enabled William of Normandy to champion the ecclesiastical cause and obtain papal support for his invasion of 1066. (D. D. McG.)

ROBERT the Devil, legendary son of a duke of Normandy, who, at 20, uses his immense strength only for outrage and crime. His mother informs him, in explanation of his evil impulses, that he was born in answer to prayers addressed to the devil; and a hermit, to whom the pope directs him, requires him as a penance to maintain absolute silence, feign madness, take his food from the mouth of a dog and provoke ill-treatment from the common people without retaliating. Later, while the emperor's court fool, he appears as an unknown knight at the bidding of a celestial messenger and delivers Rome from Saracen attacks in three successive years; his disguise is pierced by the emperor's dumb daughter, who recovers speech to identify him, but he refuses her hand and withdraws to end his days with the hermit.

This legend is found in a late 12th-century romance, *Robert Le Diable,* ed. by E. Löseth for the Société des Anciens Textes Français (1903). Another version, in which Robert is a bandit who, in penitence, kills his accomplices, feigns madness, is recognized as son of the duke of Normandy and is married by the pope to the emperor's daughter, forms the subject of the 14th-century *Mystère de Robert le Diable* ed. by E. Fournier, 1879. For another 14th-century version, in alexandrine quatrains, *see* K. Breul, *Le dit de Robert le Diable,* in *Abhandlungen Prof. A. Tobler dargebracht* (1895). The legend, distorted, also provides the Eugène Scribe libretto for Meyerbeer's opera, *Robert le Diable* (1831).

ROBERT, HENRY MARTYN (1837–1923), the author of a notable book on parliamentary procedure, *Robert's Rules of Order,* and a U.S. army general, was born in Robertville, S.C., May 2, 1837. He graduated from the U.S. Military Academy at West Point in 1857 and was commissioned in the Corps of Engineers. He served in the Union Army as an engineer and was assigned to various posts, one being at New Bedford, Mass. It was there that, as a young lieutenant, he was called upon to preside at a church meeting in which there was much controversy. Since he knew nothing of parliamentary procedure, the meeting accomplished nothing. This experience led him to make a study of parliamentary procedure, during which he found that there was no uniformity of rules. He then undertook the task of formulating a set of rules that would represent the best of the many different procedures he had discovered.

Years later, when he had completed his work, he met with disappointment. Publishers said there was no need for such a book and that no one would believe that an army officer could know enough about parliamentary law to write one. He had to offer to give away 1,000 copies to legislators, educators, clergymen, and others, with a request for their criticisms, and to assume all financial responsibility until the publisher was completely reimbursed. Finally, on Feb. 19, 1876, his *Pocket Manual of Rules of Order* was published and became an immediate success. Critics then said that no lawyer or legislator could have written the book, for he would have been bound by precedents; General Robert had broken with precedent whenever necessary. In 1915 he published a revised and enlarged version entitled *Robert's Rules of Order Revised.* More than 2,000,000 copies were sold and it became the standard manual on the subject in the United States. Robert's other works include *Parliamentary Practice* (1921) and *Parliamentary Law* (1922). He died in Hornell, N.Y., on May 11, 1923.

(S. H. Ro.)

ROBERT, HUBERT (1733–1808), French painter, sometimes called "Robert des Ruines" because of his paintings of Roman ruins, was born in Paris on May 22, 1733. His first teacher was the sculptor Michel Ange Slodtz. He went to Rome in 1754, where he had to pay a small fee for his keep at the French academy before receiving a formal appointment. French travelers to Italy began to purchase his views of Rome. In 1759 the abbé de Saint-Non and the painter Jean Honoré Fragonard, his elder, joined him and they traveled to Tivoli and Naples. Living at the Villa d'Este, they produced a quantity of drawings in red chalk of ancient buildings in ruined parks, animated with small figures. After his 11-year stay in Italy, Robert left the country in 1765, and became a member of the Paris academy the next year.

Robert was a born decorator and his paintings looked well on the gray wainscoting then much used. His popularity was enhanced by exhibitions at the Salons from 1767 on. In addition to his Italian landscapes, he painted scenes of Ermenonville, Marly and Versailles, near Paris, and of the south of France, with ruined monuments of the Roman era. During the Revolution he was imprisoned but continued his work; the fall of Robespierre saved him from the guillotine. He worked with Fragonard on a commission for the Musée Français, then a national museum in the old palace of the Louvre. He died in Paris on April 15, 1808, entirely forgotten. He is represented by works at the Louvre, Paris, the Versailles palace and many French museums; the Metropolitan museum, New York city, the Institute of Fine Arts, Detroit, Mich., and the Art Institute of Chicago.

(M. N. B.)

ROBERTS, SIR CHARLES GEORGE DOUGLAS (1860–1943), Canadian poet and prose writer, is often referred to as the father of Canadian literature. He was the first poet to express the new national feeling aroused in Canada by the Confederation of 1867, and his example and counsel inspired a whole school of late 19th-century Canadian poets.

Roberts was born near Fredericton, N.B., Jan. 10, 1860. After graduation from the University of New Brunswick in 1879, he taught school, edited the influential Toronto magazine *The Week,* and was for ten years professor of English at King's college, Windsor, N.S. In 1897 he moved to New York city where he worked as a journalist, and in 1907 he went to London. Upon his return to Canada in 1925, he was enthusiastically received on a cross-Canada lecture tour and later settled in Toronto as the acknowledged dean of Canadian letters. He was knighted by King George V in 1935. He died in Toronto on Nov. 26, 1943, and was buried in Fredericton.

Roberts was almost equally adept at prose and poetry. His prose included a pioneer *History of Canada* (1897), several novels dealing with the past and present of the maritime provinces, and many volumes of the animal stories that were his chief source of fame as a prose writer. In such books as *Earth's Enigmas* (1896), *The Kindred of the Wild* (1902) and *Neighbours Unknown* (1911) he displayed his intimate knowledge of the woods and their animal inhabitants.

Later criticism, however, tended to value Roberts' poetry rather more highly than his prose. Beginning with *Orion* (1880), he published about 12 volumes of verse, of which the best were *In*

Divers Tones (1887), *Songs of the Common Day* (1893), *The Vagrant of Time* (1927) and *The Iceberg and Other Poems* (1934). *Selected Poems,* edited by Desmond Pacey, was published in 1956. Roberts wrote of nature, love, nationalism and philosophy, but his best poems by general consent were his simple descriptive lyrics about the scenery and rural life of New Brunswick and Nova Scotia.

ROBERTS, FREDERICK SLEIGH ROBERTS, EARL (1832–1914), British field marshal famous for his achievements in Afghanistan and in the South African War, was born at Cawnpore, India, on Sept. 30, 1832, the younger son of General Sir Abraham Roberts. Commissioned in the Bengal artillery in 1851, he was appointed in 1856 to the quartermaster general's branch of the staff, with which he was to serve for the next 22 years. He first distinguished himself in the Indian Mutiny (1857–58), in which he was continuously engaged in some of the severest fighting, and was awarded the Victoria Cross. After the Umbeyla campaign on the northwest frontier (1863), he was in Abyssinia as assistant quartermaster general during the campaign of 1868, and again saw service on the northwest frontier of India in the Lushai expedition (1871–72).

In 1878 Roberts was appointed to command the Kurram field force, one of the three columns organized to operate against Afghanistan in the Second Afghan War (1878–80), and in December 1878 he skilfully forced the Peiwar Kotal, a pass leading from India into Afghanistan, and defeated the Afghan Army. The murder, in September 1879, of Sir Pierre Louis Cavagnari, British envoy to the Afghan amir Yakub Khan, led to operations against Kabul, the capital of Afghanistan, which Roberts successfully occupied in October after the complete defeat of the Afghans at Charasia, south of Kabul. However, dissatisfaction incited by the preaching of the mullahs led to a sudden attack against Kabul by the Afghan tribes in December and after heavy fighting Roberts again defeated the enemy with great loss. A new amir, Abdurrahman Khan, was installed in July 1880, and the British troops were about to be withdrawn when news was received of a reverse at Maiwand (July 27, 1880) and of the siege of the British garrison of Kandahar by a large Afghan army under Ayub Khan, Yakub Khan's brother. Within a few days Roberts, who had been perfecting the transport arrangements in his force, had begun his celebrated march from Kabul to Kandahar, where, after covering 313 mi. in 22 days, he totally defeated the Afghan Army. Roberts was already known to his colleagues as a highly competent and careful staff officer, as a brilliant tactician in command of troops, and as a commander whose care for the well-being of his men earned him their devotion. The name of "Bobs" now became a household word in Britain.

After commanding the Madras army from 1880 to 1885, Roberts became commander in chief in India in 1885, and in the following year personally supervised the task of suppressing dacoity (robbery by armed gangs) in Burma. After eight years in the highest Indian military appointment, during which time he was active in measures for improving the efficiency and well-being of the army, in particular the improvement of communications to the northern frontiers and of the standards of field training, he returned to England in 1893. He was created Baron Roberts of Kandahar in 1892 and in 1895 he became a field marshal and took command of the forces in Ireland.

The reverses in the early weeks of the South African War (1899–1902) led to Roberts' appointment to command the British forces. Within a few months his conduct of operations completely changed the course of events and, after the occupation of Pretoria on June 5, 1900, he handed over the command to Lord Kitchener and returned to England in 1901. He was created an earl and became the last commander in chief of the British Army. His long service in India had not, however, fitted him for service in the war office, the organization of which he found unfamiliar, and, apart from reforms in training methods, he did not achieve a great deal. As a result of the Esher Committee's recommendations for the reorganization of the war office in February 1904, his office was abolished when the army council was instituted.

Roberts now devoted himself to the encouragement of his fellow countrymen in rifle shooting, and to the uphill task of persuading the country that the threat of war in Europe necessitated the adoption of compulsory national service. He made many speeches in all parts of the country but, despite much influential support, was unable to induce the government to introduce the measure, which was not adopted until 1916. After the outbreak of World War I he went to France in November 1914 to visit the Indian divisions which had recently arrived. There he contracted pneumonia and died at Saint-Omer on Nov. 14, 1914. He was buried in St. Paul's Cathedral, London.

Roberts' works included *The Rise of Wellington* (1895), *Forty-One Years in India,* two volumes (1897), *A Nation in Arms* (1907), *Fallacies and Facts* (1911), and *Letters Written During the Indian Mutiny* (1924).

ROBERTS-AUSTEN, SIR WILLIAM CHANDLER (1843–1902), English metallurgist noted for his researches into the physical properties of metals, was born in Kennington, Surrey, March 3, 1843. At the wish of his uncle, Maj. Nathaniel L. Austen, he later adopted the name commemorated in the term austenite for the solid solution of carbon in gamma iron (*see* IRON AND STEEL INDUSTRY: *Steel Metallurgy: Slowly Cooled Steels*). Educated at the Royal School of Mines, he became private assistant to the master of the mint (1865) and chemist to the mint (1870), chemist and assayer (1882), and acting deputy master (1902). He became professor of metallurgy at the School of Mines in 1880. An outstanding teacher, he won renown for his work in the new field of physical metallurgy, much of which formed the basis of the alloys research reports of the Institution of Mechanical Engineers. He served on the treasury committee entrusted with the establishment of the National Physical Laboratory (1897) and was an original member of the war office explosives committee (1899). Among the many honours bestowed upon him was fellowship in the Royal Society (1875). He died in London on Nov. 22, 1902. (C. W. D.)

ROBERTSON, FREDERICK WILLIAM (1816–1853), well-known and influential Anglican preacher, commonly known as Robertson of Brighton, who in his powerful and thoughtful sermons faced some of the intellectual and social problems of his day with a refreshing and unusual honesty, was born into a military family on Feb. 3, 1816, in London. In 1837 he went to Oxford to study for the ministry, having relinquished an earlier intention of entering the army. In 1840 he was ordained, and in 1842 became curate of Christ Church, Cheltenham. After brief periods as minister to the English congregation at Heidelberg and rector of St. Ebbe's, Oxford, he was appointed to Holy Trinity Chapel, Brighton (1847), where he acquired an astonishing reputation as a preacher. His convictions had been originally of a narrowly evangelical type, but they gradually broadened. Like F. D. Maurice, whom he in some ways resembled, he was wholly out of sympathy with the party controversies of his time. His early death (at Brighton on Aug. 15, 1853) was perhaps connected with the bitterness of the opposition which his preaching aroused. Not a scientific theologian, he was a man of independent and penetrating insight.

Robertson's sermons were published in five series (1855–90). *See* also S. A. Brooke (ed.), *Life and Letters of F. W. Robertson,* 2 vol. (1865). (A. MACD. A.)

ROBERTSON, THOMAS WILLIAM (1829–1871), English playwright, who, by his realistic social comedies and his pioneer work as a producer, helped to bring about the late-19th-century revival of drama in England, was born at Newark-on-Trent, Nottinghamshire, on Jan. 9, 1829, of a theatrical family. His father became manager of the traveling repertory company on the Lincoln circuit, his mother was an actress in the company

and the youngest of his many brothers and sisters became famous as Dame Madge Kendal, the wife of W. H. Kendal (*q.v.*). After leaving school (1843), Robertson helped his father in various capacities until the company disbanded in 1848, when he moved to London and continued to act, though without much success, for another ten years. His most profitable engagement was in 1854 when he acted as prompter to Charles James Mathews and Mme Vestris (*qq.v.*) at the Lyceum Theatre, for it was their work in refining the staging of comedy that he was later to perfect.

In 1856, he married the actress Elizabeth Burton, and thereafter gradually abandoned acting for journalism. He had written for the theatre since his youth, and the first of many adaptations and translations from the French, *The Chevalier de St. George,* had been produced at the Princess's Theatre, London, in 1845. His first original play, *The Cantab,* a one-act farce, was staged at the Strand Theatre in 1861; and with *David Garrick* (based on the French *Sullivan,* by "Mélesville"), presented by E. A. Sothern at the Haymarket (1864), he established himself as a playwright. Although its characters are still recognizable theatrical types and its plot and situations are conventionally handled, in its detailed directions for sets, scenery, and costumes, and for gestures and grouping, it foreshadows his later work.

In 1865, *Society,* the first of the so-called "cup-and-saucer" comedies which made Robertson famous, was produced at the Prince of Wales's Theatre, under the management of Marie Wilton and Squire Bancroft (*q.v.*). It was followed by *Ours* (1866), *Caste* (1867), *Play* (1868), *School* (1869), and *The M.P.* (1870). In these plays Robertson the playwright and Robertson the producer combined to establish a delicately conceived and convincingly executed picture of the social scene. Although the broader themes suggested by the titles are merely touched on, they give unity to his presentation of the life of his time, and his delineation of his characters as individuals rather than types, his skilful manipulation of plot, and his easy, conversational dialogue make his plays still interesting, despite their sentimentality. As a producer, his insistence on the performance as a whole, on adequate rehearsal, and on detail, was encouraged by the intimacy of the small theatre, the "ensemble" playing of the Bancrofts and their company, and the success of the plays themselves, which ensured a long enough run for the actors to settle into their parts.

Robertson's first wife died in 1865 and in 1867 he married Rosetta Feist, who was of German birth. He died in London on Feb. 3, 1871. Several of his plays long remained in the repertory, and *Caste* is still performed, but it was primarily his staging methods which proved so influential on the course of English drama.

(GE. R.)

ROBERTSON, WILLIAM (1721–1793), Scottish historian and Presbyterian minister, whose writings were the earliest popular histories within their respective fields and were highly esteemed by his contemporaries. He was born at Borthwick, Midlothian, on Sept. 19, 1721. After being educated at Dalkeith grammar school and Edinburgh University, he was presented to the living of Gladsmuir, near Edinburgh, in 1743. A member of the General Assembly from 1746, he was elected moderator in 1762 and for many years his influence as leader of the "moderate" party was supreme. (*See* PRESBYTERIANISM.)

Robertson's career as historian began with the publication of *History of Scotland during the Reigns of Queen Mary and of James VI until his Accession to the Crown of England,* 2 vol. (1759), which brought immediate fame and was eulogized by, among others, David Hume and Edward Gibbon. It also gained the favour of Lord Bute, who secured Robertson's appointment as principal of Edinburgh University in 1762 and revived the office of historiographer royal for him in 1763. Robertson's next work was *History of the Reign of the Emperor Charles the Fifth,* 3 vol. (1769), and this was followed by *History of America,* 3 vol. (5th ed., 1788). Robertson's reputation has not stood the test of time. His concern for the "dignity of history" often seems mere pomposity and his straightforward prose is often dull. He had the virtue of adhering closely to his sources, but, as a corollary, held that those early periods of history which were poorly documented deserved to be forgotten. Of his three major works, the *History of America* (in effect, Spanish America) was the most outstanding and for this Robertson would undoubtedly be more widely remembered were he not unfortunate in having been followed by W. H. Prescott.

See J. B. Black, *The Art of History* (1926); R. A. Humphreys, *William Robertson and his "History of America"* (1954).

ROBERTSON, SIR WILLIAM ROBERT (1860–1933), British field marshal and chief of the Imperial General Staff during the greater part of World War I, was born at Welbourn, Lincolnshire, on Jan. 29, 1860. After serving in the ranks of the 16th Lancers (1877–88), he was commissioned in the 3rd Dragoon Guards. He served in India in frontier operations and on the intelligence staff before returning in 1896 to England where he became the first officer from the ranks to pass through the staff college at Camberley (1897). He was on the intelligence staff during the South African War (1899–1902) and became commandant of the staff college (1910) and director of military training at the war office (1913). At the outbreak of World War I in 1914 he served as quartermaster general of the expeditionary force in France and in January 1915 was appointed as chief of General Staff to Sir John French. He became chief of the Imperial General Staff in December 1915 and supported Sir Douglas Haig in stressing the importance of the Western front in the face of continuous government attempts to disperse the British forces on other projects. These difficulties led to Robertson's transfer in February 1918 to the Eastern command in England. From 1919 to 1920 he commanded the British army of occupation on the Rhine. He was created a baronet in 1919 and a field marshal in 1920. He died in London on Feb. 12, 1933. Robertson was a man of great character, rugged, tenacious, and cautious; but, although a clear and concise writer, he was unable to express himself effectively in speech.

He wrote two books of memoirs, *From Private to Field-Marshal* (1921) and *Soldiers and Statesmen 1914–18,* two volumes (1926).

(R. G. TH.)

ROBERVAL, GILLES PERSONNE (PERSONIER) **DE** (1602–1675), French mathematician, whose most important work was done on curves, was born at Roberval, near Beauvais, on Aug. 8, 1602. In 1632 he became professor of mathematics in the Collège de France and maintained this position until his death in Paris on Oct. 27, 1675.

Roberval studied the quadrature of surfaces and the cubature of solids, which he accomplished in some of the simpler cases by developing and improving B. Cavalieri's method of indivisibles. He discovered a general method of drawing tangents, by considering a curve as described by a moving point whose motion is the resultant of several simpler motions.

He also discovered a method of deriving one curve from another, by means of which finite areas can be obtained equal to the areas between certain curves and their asymptotes. To these curves, which were also applied to effect some quadratures, Evangelista Torricelli gave the name of "Robervallian lines." Roberval was an irascible person who indulged in scientific feuds with several of his contemporaries, among them René Descartes. He invented the balance which goes by his name (*see* WEIGHING MACHINES).

His works were published in 1693 by the Abbé Gallois, in the *Recueil* of the *Mémoires de l'Académie des Sciences.*

See E. Walker, *A Study of the Traité des indivisibles of G. P. de Roberval* (1932); J. F. Scott, *A History of Mathematics* (1958).

(O. OE.)

ROBES, the name generally given to a class of official dress, especially as worn by certain persons or classes on occasions of particular solemnity. The word robe (*toga*) was earliest used, in the sense of a garment, of those given by popes and princes to the members of their household or their great officers. It would be going too far to assume that, for example, peers' robes were originally the king's livery, but in most early cases where robes

are mentioned, if not of cloth of gold, etc., they are of scarlet, furred. A robe is properly a long garment (*toga talaris*), and the term "robes" is now applied only in those cases where a long garment forms part of the official dress, though in ordinary usage it is taken to include all the other articles of clothing proper to the full dress in question. The term "robes," moreover, connotes a certain degree of dignity or honour in the wearer. It is proper to speak of the sovereign's robes of state, of peers' robes, of the robes of the clergy, of academical robes, judicial robes, municipal or civic robes. In the case of the official dress of the clergy a distinction must be drawn. The sacerdotal vestments are not spoken of as "robes"; a priest is not "robed" but "vested" for Mass; yet the rochet and chimere of an English bishop, even in church, are more properly referred to as robes than as vestments, and, while the cope he wears in church is a vestment rather than a robe, the scarlet habit which is part of his parliamentary full dress is a robe, not a vestment. For vestments, *see* VESTMENTS, ECCLESIASTICAL.

Coronation robes reflect the requirements of royal ceremonial and the sacerdotal significance of Christian kingship. The robes of the British sovereign consist of a crimson surcoat, parliamentary robe and cap of estate worn before the service. During the ceremony, the sovereign is invested with the *Colobium Sindonis*, a loose linen garment, the dalmatic or cloth of gold surcoat with girdle of the same, surmounted by the *Pallium Regale* or cloth of gold mantle and *armilla* or stole. Leaving Westminster Abbey, the purple surcoat is worn under the purple robe of estate, with the imperial state crown. Queen Elizabeth II wore these traditional robes in 1953, omitting the crimson and purple surcoats for a coronation dress, and the cap of estate. The sovereign's coronation robes are described in "The King's Coronation Ornaments," by William H. St. John Hope, in *The Ancestor*, volumes i and ii (1902), also by L. Wickham Legg (ed.), *English Coronation Records* (1901).

All countries which boast an ancient civilization have some sort of official robes, and the modern tendency has been to multiply rather than to diminish their number. In the United States few except judges of the higher courts wear robes. The scarlet judicial robes were discarded at the Revolution. Those of black silk now worn are slightly modified academical gowns. John Jay, first chief justice of the United States (1789), set the fashion by sitting in the LL.D. robe granted him by King's College (now Columbia University).

Peers' Robes.—As early as the end of the 14th century peers seem to have worn at their creation some kind of robe of honour. An illumination on the foundation charter of King's College, Cambridge, represents the peers in 1446 wearing gowns, mantles and hoods of scarlet, furred with miniver, the mantle opening on the right shoulder and guarded with two, three, or four bars of miniver, in the form of short stripes high up on the shoulder. The origin of these is as yet unknown, though it is highly probable that these scarlet and miniver (or ermine) robes approximate to those of the medieval doctors, after they had adopted scarlet about 1340: it is not certain precisely when the peers' velvet robe of estate was first used. During the reign of Henry VIII, references are found to the "parliament robes" of peers. By the time of James II's coronation, the baron and viscount had the velvet robes of estate. The colour of these seems to have been crimson at first, sometimes varying to purple. They consisted of a long gown or surcoat with girdle, a mantle lined with ermine, a hood and a cape of ermine, the rows being as follows: for a duke 4, a marquess $3\frac{1}{2}$, an earl 3, a viscount $2\frac{1}{2}$, and a baron 2.

Till late in the 18th century peers continued to attend the House of Lords in parliamentary robes, with the stars and ribands of their orders, but robes now are worn only in the House of Lords, *e.g.*, at the opening of Parliament, on occasions when the sovereign gives his (or her) assent to bills by "royal commission" (when five or six peers on the government side appear in robes and the lord chancellor also wears his peer's robe of scarlet ermine), and at the introduction of a newly created peer or peeress, when the new peer or peeress and his or her two introducers wear their parliamentary robes (over morning dress) during the ceremony of introduction only. The mover and seconder of the address no longer wear robes, but uniforms. On all the above occasions, and when the peers as a body attend church or some other ceremony, the parliamentary robe of scarlet cloth is worn; at the present day it takes the form of a mantle opening on the right shoulder, with a collar of ermine, and guarded with rows of ermine and gold lace round the right shoulder, varying in number according to the rank of the wearer. The modern coronation robes consist of a crimson velvet surcoat and a mantle with a cape of ermine and with rows of ermine as in the parliamentary robes. The surcoat is no longer a gown, but a short sleeveless garment.

As regards peeresses' robes, the order of the earl-marshal for the regulation of these at the coronation of James II shows that by then all peeresses wore the robes of state of crimson velvet and minutely regulates all details, such as shape, powderings, length of train, and width of the fur edging of the mantle. They have changed very little up to the present day. Peeresses created for life, when introduced into the House of Lords for the first time in October 1958, wore normal parliamentary robes with a hat of tricorn pattern.

House of Commons.—The speaker of the House of Commons wears on state occasions a black damask robe with gold lace and a full-bottomed wig; in the house itself he wears a black silk robe with train and a full-bottomed wig. The clerks at the table wear barristers' gowns and wigs.

Robes of the Orders of Knighthood.—The robes of the Garter were originally of blue woolen stuff, the surcoat and hood being powdered with garters embroidered in silk and gold. The surcoat varied in colour from year to year; the hood was made of the same material as the surcoat and, when hats began to be worn, was carried hanging over the shoulder. Robes were sometimes granted to ladies in the early days. The last lady to receive the robes was Margaret, countess of Richmond, in 1488. At the present day the mantle is of dark blue velvet, of the same colour as the riband, lined with taffeta, and with the star embroidered on the left shoulder. The hood and surcoat of crimson velvet are lined with white taffeta, and with these are worn a doublet and trunk hose of white satin and a plumed hat.

The robes worn by the knights of the Bath created at the coronation of Henry IV were green with furred hoods and a white silk cord hanging from the left shoulder. The mantle at the present day is of crimson velvet lined with white over a white satin undercoat and trunk hose, and a plumed hat and white boots with red tops are worn. The mantle of the Thistle is of dark green velvet over surcoat, etc., of cloth of silver; that of St. Patrick azure, with doublet and trunk hose of white satin; that of St. Michael and St. George of Saxon blue satin lined with scarlet; and that of the Star of India of light blue satin lined with white.

Judicial and Forensic Robes.—It is frequently stated that judicial robes had their origin in the dress of ecclesiastics. But though ecclesiastics in early days frequently acted as judges and though, as Sir John Fortescue says, the serjeant's long robe was "after the fashion of a priest," judicial robes more probably arose from the ordinary civilian dress of the early 14th century. The chief argument for their ecclesiastical origin has been found in the coif, a cap of white linen or silk, tied under the chin, and described by Fortescue as "the principal or chief insignment and habit wherewith serjeants-at-law at their creation are decked," which is said to have been used by ecclesiastics to hide the tonsure when in court. More probably the coif was a headdress in common use in the 13th century, which survived as the distinguishing mark of men of law. The scarlet judicial robe trimmed with white fur (ermine or miniver) together with a hood of scarlet cloth lined with white fur undoubtedly represent the survival for specialized use of the robes of the pre-Reformation doctors in canon law (*decretorum doctor*). About 1340 the doctors in theology and in canon law adopted scarlet robes and hoods, lined with miniver, and silk linings were adopted for summer use about a century later. An ecclesiastical origin is correctly assigned to these, inasmuch as, prior to the Reformation, all the members of the two ancient universities were in holy orders, or at least belonged to one of the lower clerical grades.

About the time of Queen Elizabeth I the square cap (*pileus*

quadratus), otherwise known as the cornered, black, or sentence cap (the last from the fact of its being put on by the judge when pronouncing sentence of death), began to appear. Sometimes it was worn over the coif only, sometimes over the coif and skullcap. Sometimes it had ear flaps, sometimes, as at present, not.

Toward the end of the 17th century the judges took to wearing wigs, and they have continued to wear them ever since. The wearing of wigs naturally concealed the coif and velvet skullcap, so a device had to be invented by which they could still be displayed. The expedient was hit upon of putting a round patch of white stuff, with a black spot in the middle of it, on the crown of the wig of certain of the judges, to represent the coif and skullcap. Serjeants being appointed no longer (*see* above), this round patch has now disappeared, the only trace of it left being the circular depression on the crown of the wig. Minute details of court and levee dress, judicial and legal, of the present day, will be found in *Dress Worn at Court*, issued with the authority of the lord chamberlain—also details of mourning costume.

Municipal and Civic Robes.—The word "livery," the use of which is now practically confined to the official dress of the "livery companies," the dress of menservants, etc., originally meant an allowance of food or clothing granted to certain persons. It is still used of the allowances of food made to the fellows of certain colleges. As early as the 13th century, the citizens of London used to assume a uniform dress to do honour to some great occasion, as when 600 citizens rode out to meet Queen Margaret of France, second wife of Edward I, "in one livery of red and white, with the cognizances of their misteries embroidered upon their sleeves." By the 14th century there is evidence of the adoption of liveries by the trades and fraternities, and when the livery companies were incorporated they took care to have their liveries authorized by their charters. The scarlet, violet, and black robes still worn by the mayor, aldermen, sheriffs, etc., were early in use. The provincial mayors and aldermen at quite an early date followed the fashion of London, wearing what are virtually sleeved tabards. An account of the robes of modern provincial mayors will be found in William H. St. John Hope (ed.), *Corporation Plate . . . of the cities . . . of England and Wales* (1895).

At the present day the lord mayor has several sets of robes: a special coronation robe, a crimson velvet robe of state like that of an earl, worn with the chain and jewel, *e.g.*, in the presence of the sovereign when in the city; a black robe of state trimmed with gold, which is worn with the chain and jewel, *e.g.*, at the Guildhall on lord mayor's day; the scarlet robes, which are worn, with or without the chain, on most public occasions, such as the service at St. Paul's on the first day of the Easter law term, audiences of the sovereign, the election of the lord mayor, the opening of the central criminal court, etc.; a violet gown, which is worn, *e.g.*, when the lord mayor elect is presented to the sovereign, when he is sworn in, at the election of sheriffs, etc.; and a black gown worn in church on Good Friday, etc. The aldermen wear scarlet on most occasions of ceremony, former mayors "having the Cap of Dignity attached to their gown, and being entitled to introduce a sword and mace into their badges." They also wear violet robes on certain occasions marked in the almanac of the *Alderman's Pocket-Book*, and black gowns when the lord mayor wears his. The sheriffs and recorders have scarlet, violet, and black gowns, and the members of the common council have deep mazarine blue gowns, which seem to have been first prescribed in 1761. (X.)

Academical Dress.—Like judicial robes, academical dress has been considered to be of ecclesiastical origin. The medieval scholar was, of course, a clerk and had to wear the clerkly gown and the tonsure. The ecclesiastical dress that he wore had itself probably developed out of the ordinary civilian dress at an earlier period. The robes worn in the earliest times at Oxford and Cambridge, at least in part, were monastic or ecclesiastical in origin, but the hood was certainly derived from a lay garment, at one time common to all classes and both sexes, as Herbert Norris pointed out (see *Bibliography*). This lay hood was adopted by monks, clergy, and all university students, and eventually was retained in a specialized form by the various faculties, as an academical distinction. The statutes of certain colleges required of the scholars as early as the 14th century the tonsure and a "decent habit" suitable to a clerk; *i.e.*, a long gown, which it is stipulated in some cases must be closed in front like the Benedictine habit. Some colleges had liveries, prescribed perhaps by the founder of the college and laid down by the statutes. The differences of colour and shape in the undergraduate gowns of most of the Cambridge colleges are supposed to be a survival of this, but in fact the Cambridge college undergraduate gowns all date from the period 1805–40; *i.e.*, are late Guelphic (that is, Hanoverian) in origin and thus quite modern.

The gown was worn by all grades as befitting clerks. It is hard to determine whether there was at first any difference between the gowns of the senior nongraduates and the bachelors of arts and that of the masters and doctors and the bachelors in the superior faculties, but it seems improbable. It was frequently fur-lined, or at least trimmed with fur, but the use of the more costly furs was forbidden, especially in the period between 1350–1500, to all below the degree of master, except sons of noblemen, or those possessing a certain income, bachelors using budge (common fur or black lamb's wool); students and even doctors in theology were also, at one time, restricted to budge, lamb's wool, and to sombre habits. The robes of masters had to be flowing and reach to the ankles (*toga talaris*), and it was the masters who had the earliest distinctive dress that could be called truly academical.

The cope (*i.e.*, the *capa* or *cappa clausa*, the closed and essentially ecclesiastical cope or cape, not to be confused with the open and purely decorative cope of the clergy) probably originated in the ordinary everyday mantle of the clergy. Its wear in England was made obligatory by Archbishop Stephen Cardinal Langton, 1222, at the provincial synod held at Oseney Abbey, near Oxford. All bishops, deans, archdeacons, rural deans, priests, and all church dignitaries were ordered to wear it. This kind of cope, closed in front, was originally black; sometimes, for the sake of convenience, it had a slit in front to allow of the passage of the hands, this type of opening being the form or variation adopted by the doctors in theology and retained by them until the present day, although later on the slit was extended to the ground. Another variation was to make two side slits, one for each arm, a variation (the pallium or *chimaera*) adopted by the doctors in law and in physic and by the superior bachelors; *i.e.*, the bachelors in canon law, physic, and possibly in theology. This type is the forerunner of the convocation habit and ecclesiastico-academical chimere.

About 1330–40 doctors began to adopt scarlet for their hoods and later for their robes; at any rate by about 1500, probably long before, all doctors wore scarlet and had discarded their black *cappae clausae* for scarlet ones, the original sombre, black form being retained by the M.A.'s and B.D.'s. The wearing of robes of scarlet, violet, or murrey, and also the "sleveless cote" (*i.e.*, convocation habits and chimeres), *supertunica*, of these colours, was formally ratified by an act of 24 Henry VIII (1533, *caput* 13) entitled "an Act for the Reformation of Excess in Apparel." The cope still survives at Cambridge as the dress worn by the vice-chancellor and by regius professors of divinity, law, and medicine when presenting for degrees; it is lined with white fur.

The hood was originally worn by all scholars, as by everybody, and had evidently no academical significance. Sometimes a cap was worn also, the hood being thrown back. There were evidently hoods of two kinds for masters from about 1432, when masters and doctors were allowed to use silk in their linings during the summer months, so that there were silk-lined and miniver-lined hoods. These two types of hood survived, at least in Oxford, until as late as 1657, or even a little later, in the time of John Fell, dean of Christ Church and vice-chancellor, and Anthony à Wood, M.A., the antiquary. Eventually (from about 1674–75, in the time of George Edwards and David Loggan) the silk-lined hood was the type principally retained by masters and doctors, the miniver-lined hood being preserved as a proctorial insignia only. At a later date, at Cambridge, a distinction was made between the hoods of nonregent masters, which were lined with silk, and those of regents, which were lined with miniver. Later again, the regents wore their hoods in such a way as to show the white lining, while

the nonregents wore theirs "squared," so that the white did not show. Hence the name "white hoods" and "black hoods" given to the upper and lower houses of the old senate, respectively. It is not settled when the modern colouring of hoods arose; they probably followed those of the robes of the faculties, but about these there is equal uncertainty. The Oxford proctor still wears a miniver-lined hood. The modern Oxford doctors' and B.D., and the Cambridge hoods have preserved the original shape more closely than the Oxford M.A. type, being a hood and cape combined, the cape having at Cambridge now, incorrectly, square corners: the cape, being semicircular, should be rounded.

There seem to have been in Tudor times at least three varieties of academical headdress; one, the round cap of velvet for graduates in the secular faculties, survives as part of the full dress of doctors (except doctors in theology) to the present day. The square cap was adopted at the universities, according to N. F. Robinson, after 1520, in imitation of the University of Paris. In this connection should be mentioned the term "tuft-hunting" (*i.e.*, attempting to thrust oneself into the society of one's social superiors), derived from the gold tufts or tassel worn by noblemen and fellow commoners on their college caps. Originally, in the two ancient English universities, no one wore a cap except doctors in the superior faculties of theology, canon law and physic. The type of cap they wore was a tight round skullcap type, with a little point at the crown: it was called the pileus, and was thus a cap of dignity. All other graduates and nongraduates had their hoods, which were thus a shoulder cape and a covering for the head. It appears that in Paris caps were made by sewing together four pieces of cloth, and the seams produced little raised ridges, and had a squaring effect. From this particular cap (squarish in effect), two types of cap evolved: (1) the biretta or priest's cap, simply a stiffened, rather taller pileus, made of the four pieces of cloth, and (2) the academical or doctor's cap (*pileus quadratus*), a velvet cap of dignity for doctors in theology. Doctors in the secular faculties adopted in the early Tudor period a soft round lay cap of velvet (*pileus rotundus*). Foundation choristers and scholars were permitted square caps in 1549. Between 1549 and 1580 there were frequent rulings and fresh statutes issued on the subject of caps. B.A.'s and other junior graduates were not authorized to wear caps until between 1575 and 1580, and then only "humbly and submissively in the Schools." By 1580 a cap had been established for all members of the two ancient English universities, and the restriction to doctors and senior graduates had broken down. The beautiful series of illustrations of the academical dress in the Bodleian Library at Oxford, by George Edwards and by David Loggan, 1674 and 1675, respectively, show the caps then in use.

Academical dress underwent much inquiry and some revision at the time of the Reformation, chiefly in the direction of sobriety, uniformity, and laicization, "excess of apparel" being repressed as severely as ever, but not with much more effect. There have been few far-reaching changes since the Laudian Code of 1636. Cambridge in the 20th century (1932–34) inquired into and revised its regulations as to dress, after a subcommittee of the senate had submitted three reports, and in the *Ordinances* clear rules are laid down, published in the University Reporter (Feb. 28, 1934). The Oxford regulations have not been revised since 1770, and have now fallen into chaos. Some of them are dead letters: at Oxford one hood (the pale blue B.Litt. hood of 1895) by 1940 had come to be worn for four degrees, B.C.L., B.M., B.Sc., and B.Litt. The dark blue hood, lined with white fur, proper to the B.C.L. and B.M. degrees, was no longer to be seen at Oxford. The modern robe makers sell the pale blue silk B.Litt. hood, lined with white fur, for all four degrees and for the B.Phil. In 1957–58 a new hood was invented for the B.Phil. degree. This is of the debased Oxford M.A. pattern, of dark blue ribbed rayon lined with white silk: the white silk takes the place of the white fur. It is, in fact, a freak hood. The B.Mus. hood, originally dark blue like B.C.L. and B.M., was, before World War I, of dark purple: by 1945 or so it had become a brilliant lilac.

In the absence of any official regulations, the Oxford branch of the National Federation of Merchant Tailors drew up in 1957 an illustrated catalogue of what they described as the correct colours and materials of the various robes. This catalogue is said to have been approved by Congregation and it was deposited in the Bodleian. But some of the colours are still incorrect. Congregation never appointed a subcommittee to thresh out the whole subject, as did Cambridge in 1932–34, and thus, at Oxford, the tailors have prescribed for the university.

Doctors of both universities have three sets of robes: first, the full-dress robe of scarlet cloth; second, the scarlet, murrey, or violet convocation habit and hood of scarlet (now at Cambridge a cope, at Oxford the so-called *cappa clausa*); third, the black gown or undress. The first is worn by all doctors except the doctor in music, and is accompanied by the round cap of velvet except in the case of the D.D., who continues to wear the square cap (or ecclesiastical cap) with all three forms of dress; strictly, the D.D. square cap should be soft, of black velvet and with a tuft, or plain without tuft or tassel. The Oxford D.D. also wears a cassock, sash, and scarf. The scarlet robe is of a different, somewhat more of a Tudor lay (or civic) shape than the M.A. and B.A. gowns: in fact it is a tabard. As now worn, it is faced with silk of the same colour as the hood silk lining of the faculty, except in the case of the Oxford D.D. full-dress robe, which is faced with and has bell-shaped sleeves of black velvet. The second or Cambridge cope now has gone almost out of use, but is still worn when presenting for degrees, etc., but only in Cambridge. It is sometimes worn over the black gown. There are several types of black gown, but the tufted gown of David Loggan's day has now gone out of use. The M.D. and Mus.D. black gowns at Cambridge are now made after the pattern of the LL.D. gown, with a square-ended sleeve and flap collar, trimmed with black lace, but the D.D., Sc.D., and Litt.D. wear the M.A. silk gown, the former with the scarf, the two latter with lace on the sleeve, placed horizontally for Sc.D. and vertically for Litt.D. Some doctors in divinity wear the full-sleeved gown with scarf. At Cambridge the headdress of a D.D. is the square cap, of secular doctors the velvet bonnet with gold cords. The doctors in music wear, as they have done since about 1600, a full-dress robe of white or cream damask brocaded silk, lined with pink satin at Oxford and with cherry-coloured satin at Cambridge. Formerly (1550 period) doctors in music at Cambridge wore the M.D. robes (*Cambridge Grace Book* Δ 1545).

The Oxford sleeveless commoner's gown, though still by statute *toga talaris*, now reaches little below the waist, the full-sleeved or bell-sleeved scholar's gown to the knee. The tufted silk gown of the gentleman commoner and the nobleman's gold-lace gown are not yet abolished by statute, but have fallen into disuse. The University of Oxford Act, 1854, brought in and passed by Gladstone, abolished these class distinctions at Oxford, although they lingered on until about 1869 at Christ Church, so that King Edward VII, as prince of Wales, wore a gentleman commoner's bell-shaped sleeved gown when up in 1860. Vice-chancellors have no official dress, but wear the robes of their degree. The chancellors of the older universities wear a black damask silk robe with gold lace and a black velvet square cap with gold tassel and band; those of the newer universities have had robes "created" by experts or by the robe makers, who are nowadays to a large extent the arbiters of academical dress, but based largely on Oxford and Cambridge customs. The Hull chancellor's and vice-chancellor's robes are of blue: these robes at Southampton are of black figured damask silk with gold ornamentation.

United States.—An intercollegiate commission in 1893 drafted a uniform code for academical caps, gowns, and hoods which has since been accepted by 800 or more degree-granting colleges and universities in the United States. Three types of gown and three types of hood have been devised for bachelors, masters, and doctors, respectively. The square caps remain the same except that the doctor's may be made of velvet and have a tassel of gold. The bachelor's gown is made of black worsted material and may be distinguished by its pointed sleeves of the B.A. Oxford type, though hanging only to the knee. The master's gown, made of silk, has closed bag sleeves of M.A. type (the arm coming through a slit at the elbow), which are square at the end and extend well below the

knee. The doctor's gown is also made of silk, and, like a judge's robe, has full round open bell-shaped sleeves, is faced with velvet and has three bars of velvet on each sleeve.

The hoods are lined with silk of the colour or colours of the college or university granting the degree and bordered with silk or velvet of the colour that represents the department of learning in which the degree was obtained. Obviously, only a very few universities, such as Harvard, Yale, and Chicago, can have a single distinguishing colour as a hood lining (crimson, blue, and maroon, respectively); other universities and colleges have to have two colours, the second or subsidiary colour being sewn inside as a chevron; Cornell and Cincinnati have two chevrons. This system, though distinctive and advantageous in some respects, produces a rather patchy effect, but it would be impossible to distinguish the degree hoods of about 800 degree-granting colleges or universities without such a device. Colours of the faculties are: arts, white; theology, scarlet; law, purple; medicine, green; music, pink; philosophy, dark blue; science, golden yellow; letters, white; engineering, orange; economics, copper; public health, salmon pink; agriculture, maize; fine arts, brown; accountancy and commerce, drab; library science, lemon; veterinary science, gray. The velvet trimming of the doctor's gown may also be of the departmental colour or it may be black if preferred.

The U.S. system of hoods is, therefore, progressive and enables anyone conversant with the system to pick out the university (by the colour or colours in the lining), the faculty (by the border on the cowl or hood portion proper), and the grade (by the size and shape, bachelors and masters having silk hoods of Oxford M.A. shape, masters' being made considerably longer than bachelors', doctors' being of cloth [rayon or silk] of the Cambridge M.A. type but with a well-rounded cape portion). The very expensive real silk is now rarely used for hood linings, man-made fabrics having taken its place.

A few institutions, notably Harvard and Yale, retain an individual code for their hoods. At Harvard, hoods for bachelors, masters, and doctors are of the simple Oxford M.A. type, of black cloth or silk; there is no border on the outside to denote the faculty. Masters' hoods are longer than bachelors'; and doctors' are longer than masters'. All these hoods are worn back to front, the liripipe being outward instead of (correctly) inward toward the back. The faculty is indicated on the gowns by "crow's-feet."

At Yale, all hoods are made of black material and are fully lined with dark blue, those of bachelors being three feet long, masters' and doctors' four feet long; and all are edged with velvet. All are of the simple Oxford M.A. type, and are worn back to front, as at Harvard.

All the institutions are governed by the intercollegiate code devised by the Intercollegiate Bureau of Academic Costume chartered by the University of the State of New York. The bureau maintains the system, adds to it when new degrees or degree-granting corporations are established; and its "repository," the firm of Cotrell and Leonard, can supply the correct hoods, gowns, and caps for any college or university of the United States.

Continental Europe.—Academical dress, as known in the United Kingdom, the Commonwealth of Nations, and the United States, is not now worn at continental universities. During the Middle Ages some countries had an academical dress, in general of the Oxford and Cambridge pattern.

In France, academical dress was in use in the University of Paris from the 13th century; and at the end of the first third of the 14th century Pope Benedict XII (Jacques Fournier), a doctor in theology of Paris, allowed doctors in canon law to wear a red shoulder cape. During the 18th century academical dress was worn less and less; until the abolition of all the universities of France by a law of the National Convention dated Sept. 15, 1793. Today, graduates of French universities wear a black or coloured gown, a round, cylinder-shaped high cap, and a silk scarf over the left shoulder, which is said to represent the tail (*liripipium*) of the medieval hood. Their rank is indicated in ascending order by one row of white fur (*bachelier*), two rows (*licencié, i.e.,* master), or three (*docteur*). The colour of the silk scarf varies according to the university.

The Italian universities of Bologna, Padua, Rome, Pisa, Florence, Pavia, and Ferrara had academical dress in the Middle Ages.

In Spain, Salamanca, Lérida, Valladolid, Huesca, Barcelona, and Alcalá universities had academical dress; as did Palma de Mallorca (Balearic Islands).

In Portugal, academical dress was prescribed for the University of Coimbra in 1321; it consisted of a gown and hood, with the addition of a cap for graduates only.

Malta's Royal University prescribes for its graduates an academical dress resembling that in Great Britain, save that there are no hoods.

German-speaking countries, Belgium and the Netherlands, and Switzerland have used academical dress; in Switzerland, Basel and Geneva universities prescribed it.

Brussels (Belgium) and Lausanne (Switzerland) are special cases, as a large number of British physicians and surgeons hold the degree of doctor in medicine of these universities and academical dress is authorized for their use in accordance with British custom. At Brussels this consists of a full-dress robe of scarlet superfine cloth of the Cambridge and London shape, the sleeves being of the open-wing type as at Cambridge. It is lined with light blue silk, and the fronts are faced with the same blue silk to a width of four to five inches. The hood also is of scarlet superfine cloth, has a rounded cape of the full or London shape, and is fully lined with light blue silk. The cap is of black velvet, round (as for London doctors), with blue cord and side tassels.

At Lausanne (of which Commonwealth physicians and surgeons also may be doctors), a full-dress robe of scarlet superfine cloth is worn, with bell-shaped sleeves (as for Oxford doctors), faced with virgin blue watered silk; the fronts of the robe are faced with the same silk. The hood is of the full or Oxford doctors' shape with a well-rounded cape, and is lined throughout with the same virgin-blue watered silk. The cap is round, of black velvet (as for London doctors), with blue cord and tassels. The undress gown is of black silk or poplin, of the M.A. Oxford type, the armhole being bound with two rows of black silk fabric (gimp) as used at Oxford.

ROBESON, PAUL (1898–), U.S. Negro actor and singer, was born at Princeton, N.J., April 9, 1898. He graduated from Rutgers College, New Brunswick, N.J., with an extraordinarily distinguished scholastic and athletic record, and in 1923 completed the law course at Columbia University. His first stage appearance was in *Taboo* (1922), but he made his reputation in *All God's Chillun Got Wings* and in the title roles in *Emperor Jones* (1923) and *Black Boy* (1926). After appearing in *Show Boat* in England, he toured the U.S., Europe, and the U.S.S.R. with recitals of Negro spirituals. Robeson entered films in 1933, playing in *The Emperor Jones, Sanders of the River,* and *Show Boat.* In 1943 he appeared in a New York production of *Othello,* which established the longest Shakespearean run in the United States.

In 1950 the U.S. State Department denied him a passport after he refused to sign an affidavit stating whether he was or ever had been a member of the Communist Party. In 1958 the U.S. Su-

preme Court ruled that refusal to sign such an affidavit was not grounds for denial of a passport, and Robeson settled in England. He made a number of trips and concert appearances in the U.S.S.R. and other continental countries and then returned to the U.S. in 1963. (M. S. Bv.; X.)

ROBESPIERRE, MAXIMILIEN FRANÇOIS MARIE ISIDORE DE (1758–1794), French revolutionary known as "the Incorruptible," a leading member of the Jacobin Club and of the Committee of Public Safety, whose name is particularly associated with the period of Terror of 1793–94. Born at Arras on May 6, 1758, he was descended from a modest bourgeois family that had settled at Carvin about 1650. His father, an advocate, fell into debt, and, after his wife died in 1764, left home and died in Munich in 1777. His orphaned children were brought up by their maternal grandparents.

BULLOZ

MAXIMILIEN ROBESPIERRE. PORTRAIT BY AN UNKNOWN ARTIST. IN THE MUSÉE CARNAVALET, PARIS

Early Life at Arras.—From 1765 Maximilien attended the college of the Oratorians in Arras; then, in 1769, he obtained one of the scholarships given by the Abbey of St. Vaast for the College of Louis-le-Grand in Paris. A brilliant student, he matriculated in 1780 and took a master's degree in law in 1781. His scholarship was then transferred to his younger brother Augustin, and Maximilien registered as an advocate at the Arras bar. He rapidly made a name for himself and was appointed a judge in the Salle Épiscopale, a court with jurisdiction over the provostship of the diocese. As a successful advocate he was assured of a comfortable living.

Robespierre also competed for academic awards and his essay "Discours sur les peines infamantes" (1784) won him a prize offered by the Société royale des Sciences et Arts at Metz. He joined the Arras literary and musical society, known as the "Rosati," and was made president of the local *académie*. Though it was rumoured at the time that he had a fiancée, his cousin Anaïs Deshorties, he never married. Already known as the advocate of the poor, in his "Mémoire pour le sieur Dupond" he harassed the privileged classes, inveighing against royal absolutism and arbitrary justice. From the time of the notification (June 1788) that the Estates-General would be called (*see* FRANCE: *History;* FRENCH REVOLUTION), he launched his appeal for electoral reform in a pamphlet, "À la nation Artésienne, sur la nécessité de réformer les États d'Artois." On March 23, 1789, the people of Arras chose him as one of their representatives and the third estate of the bailliage elected him fifth of the eight Artois members of the Estates-General. Thus began his political career: he was not quite 31 years old.

The Constituent Assembly.—Conspicuous in the Assembly by his immaculate appearance and dress, Robespierre retained throughout his life his bourgeois customs, frugality, and his strict moral code. Despite his frail appearance (he was slight in build and only 5 ft. 3 in. tall) he was of robust health. He probably made his maiden speech on May 18, 1789, and before the end of the Assembly on Sept. 30, 1791, he had voiced his opinions more than 500 times. In spite of his weak voice, and the opposition he aroused, he was nevertheless able to command the attention of its members. Described by the comte de Mirabeau as one who "believes everything he says," he was attacked by the Royalist press, excluded from the Assembly's committees and from its presidency, and only once, on June 19, 1790, elected one of its secretaries for a short time. The people, however, always supported him.

During April 1790 Robespierre was president of the Jacobin Club, of which he had been a member since its formation (*see* JACOBINS), and in October he was appointed a judge of the Versailles district tribunal. Nevertheless, he had decided to devote himself entirely to his work in the Assembly, where the constitution of Sept. 3, 1791, was being drawn up. A disciple of Rousseau, grounded in ancient history and the works of the philosophers, he welcomed the Declaration of the Rights of Man and the Citizen (*q.v.*). He fought tenaciously for universal suffrage, for unrestricted entry to the national guard, public offices, and army commissions, and for the right to petition; he opposed the royal veto, the abuses of ministerial power, religious and racial discrimination; he defended actors, Jews, and Negro slaves, and supported the demand for the incorporation (September 1791) of the papal territory of Avignon into France. It was through his efforts on May 16 and 18, 1791, that the existing deputies were debarred from reelection to the new assembly, on the grounds that a completely new assembly would better express the sovereign will of the people.

The flight and capture at Varennes (June 20–21, 1791) of Louis XVI, for which Robespierre vainly demanded the king's trial, spurred his efforts for the completion of the constitution. He foresaw the "massacre" at the Champs de Mars (July 17), when demonstrators demanding the abdication of the king were dispersed with loss of life, and afterward, fearing arrest, he went to live with a supporter, Maurice Duplay. Robespierre prevented the dissolution of the Jacobin Club after the moderate members had seceded to form the Feuillants Club (*q.v.*). His general popularity remained immense, and after the final sitting of the Assembly, the Parisians gave Robespierre, now nicknamed "the Incorruptible," and his friend Jérôme Pétion a tremendous reception, which was repeated in Artois, where he stayed briefly in October 1791.

Jacobin Club.—Although he had excluded himself from the new Legislative Assembly, Robespierre continued his political activities, giving up the lucrative post of public prosecutor at the Paris criminal tribunal to which he had been elected on June 10, 1791. Henceforth his speeches were made to the Jacobin Club, where he was heard about 100 times up to the insurrection of Aug. 10, 1792 (*see* below). There he opposed the demand of J. P. Brissot (*q.v.*) for a European war to spread the aims of the Revolution. He denounced the secret intrigues of the court and of the Royalists, their collusion with Austria, the unpreparedness of the army, and on Feb. 10, 1792, again demanded the dismissal of aristocratic officers. He also spoke for the "patriotic" soldiers, in particular those of the Châteauville regiment, imprisoned after their mutiny at Nancy in August 1790. When Brissot's supporters stirred up opposition against him, Robespierre founded, in May 1792, a journal, *Le Défenseur de la Constitution*. This new weapon strengthened his hand; he violently attacked the marquis de Lafayette (*q.v.*), the commander of the French Army, whom he suspected of wanting to establish a military dictatorship, but failed to obtain his dismissal and arrest.

The reverses suffered by the French Army after France had declared war on Austria and Prussia in April 1792 came as no surprise to Robespierre and the threat of an invasion of France rallied the people to him. But he hesitated to call for an insurrection. "You must not fight the common enemy," he told the *fédérés* (provincial volunteers) who assembled in Paris, "except with the sword of the law." When the insurrection nevertheless broke out on Aug. 10, 1792, Robespierre, like Georges Danton and J. P. Marat (*qq.v.*), did not take part in the attack on the Tuileries Palace. That same afternoon his Paris section, the *Piques*, elected him to the Insurrectional Commune of Paris. During the election to the new assembly, the National Convention, he excused the September massacres, thereby strengthening his position with the people of Paris who, on Sept. 5, elected him the first of their members in the National Convention.

The Convention.—From the very first sittings of the Convention at the end of September, Robespierre was accused of dictatorship by the Girondins (*q.v.*), the majority group. The trial of the king, which opened in December, heightened the conflict; Robespierre intervened 11 times during the course of the debates and his speech of Dec. 3 rallied those who hesitated to take action against Louis. Meanwhile he used his new journal, *Lettres à ses commettants*, to keep the provinces informed of the

course of events. The execution of the king (Jan. 21, 1793) did not, however, resolve the struggle between the Girondins and the Montagnards (as the Jacobins in the Convention were called); it was finally brought to a head only by the treason (April 1793) of Gen. Charles Dumouriez (*q.v.*), who went over to the Austrians. At the same time the scarcity of food and rising prices were creating revolutionary feeling among the people. A kind of "popular front" was formed between the Parisian sans-culottes and the Montagnards, and on May 26, 1793, Robespierre invited the people "to force their way into the Convention in revolt against the corrupt members." On May 31 he supported those petitioners who demanded in the Convention a decree indicting the leaders of the Gironde and the accomplices of Dumouriez. It was passed against 29 of the Girondins on June 2, while the debating hall in the Tuileries (to which the Convention had recently moved) was surrounded by the armed sections of Paris. The democratic constitution of 1793, finally adopted on June 24, contained several articles put forward by Robespierre, but his proposals to limit the right of private property, to proclaim the right to work for all, to introduce a graduated tax, and to create a league of nations, were rejected as being too revolutionary.

The Committee of Public Safety and the Terror.—After the fall of the Girondins, the Montagnards were left to deal with France's desperate plight. Threatened internally by the movement for federalism and by the civil war in the west (*see* VENDÉE, WARS OF THE), and on its frontiers by the anti-French coalition, the success of the Revolution depended upon the support of the entire nation. *"Une volonté une"* ("one will and one only"), Robespierre noted in his diary, and this dictatorial power characterized his view of the revolutionary government. On July 27 Robespierre became a member of the Committee of Public Safety, first set up on April 6. While many of his colleagues were away on missions, and others, such as Lazare Carnot, C. A. Prieur-Duvernois, and Jean Lindet were preoccupied with special assignments, Robespierre assumed control of the committee. He also tightened his grip on the Jacobin Club and further subjected the popular societies to his views.

One after another he denounced the "factions" that endangered the committee. In August and September he brought about the arrest of the leaders of the extreme left, the Enragés; on Sept. 4 he prevented the followers of Jacques Hébert (*q.v.*), who dominated the Commune, from taking over control of the Revolution. In his report of 5 Nivôse (Dec. 25, 1793) in the Convention he justified the collective dictatorship of the committee and the centralization of the administration, and, in order to effect mass conscription and to wage total war, he decided to intensify the Terror. "It is our weakness in dealing with traitors that ruins us," he declared, and asserted the need for a "swift, harsh and inflexible justice." But he did not advocate indiscriminate indictments, and he recalled the representatives on missions, such as J. L. Tallien, J. B. Carrier, Louis Fréron, and Paul Barras, who were disgracing the Revolution by the atrocities they authorized.

As the economic situation grew worse, Robespierre struck down the Hébertistes, who had been profiting from the distress (18 were executed on March 24, 1794), and to retain the backing of the people he supported the vote for the decrees of 8 and 13 Ventôse, year II (Feb. 26 and March 3, 1794), by which the property of suspects was to be distributed to the poor. He finally turned against the Indulgents, those who favoured peace and a lessening of the Terror, bourgeois businessmen and foreign bankers, who had given their support to Danton. After much hesitation Robespierre provided L. A. Saint-Just with the notes (a series of charges against Danton) with which he was able to secure the conviction and execution of Danton and Camille Desmoulins (16 Germinal; April 5, 1794).

Cult of the Supreme Being.—A deist, like Rousseau, Robespierre had already condemned the anti-Christian movement and the "masquerades" of the cult of Reason. He went further in his report to the Convention of 18 Floréal (May 7) affirming the existence of God and the immortality of the soul, and outlining his plan for a civic religion, the cult of the Supreme Being. Meanwhile, his popularity remained immense, as is shown by the public ovations that he received after Henri Admiral's attempt on his life (4 Prairial; May 23). He had won over the Jacobins, the Commune, the national guard, and on 16 Prairial (June 4) the Convention elected him president by 216 out of 220 votes. In this capacity he attended the inaugural festival of the Supreme Being on 20 Prairial (June 8). But overwork and the large number of speeches he made in the Convention and at the Jacobin Club (almost 450 since the opening of the Convention) began to take their toll of his health; he became irritable and aloof. After his law of 22 Prairial (June 10), reorganizing and speeding up the work of the revolutionary tribunal, a secret opposition against him began to develop, led by the representatives on missions whom he had attacked. His authority was questioned in the Committee of Public Safety, particularly by Carnot, J. M. Collot d'Herbois, and J. N. Billaud-Varenne, and the Committee of General Security, which included many of his opponents, became even more hostile. Embittered by these attacks, and by accusations of dictatorship now brought by his colleagues, the Montagnard deputies, he stayed away from the Convention and after 10 Messidor (June 28) from the Committee of Public Safety, confining his denunciations of his enemies to the Jacobin Club. At the same time he began to lose the support of the people, whose hardships continued despite the recent French victories.

Thermidor.—On 5 Thermidor (July 23) Robespierre reappeared at the Committee of Public Safety and on 8 Thermidor at the Convention. His long final speech on that day, at first gaining applause, was later received in silence, and the parliamentary majority turned against him. Next day he was prevented from speaking at the Convention, which decreed his arrest and that of his brother Augustin and his friends Georges Couthon, Saint-Just, and Philippe Lebas. Taken to the Luxembourg prison, the warden refused to take him into custody, and Robespierre later went to the Hôtel de Ville, where armed forces assembled by the Commune were awaiting his orders. But he refused to lead the insurrection, and in the early hours of 10 Thermidor (July 28, 1794) his loyal forces began to disperse. The Convention declared him an outlaw, and when their forces attacked the Hôtel de Ville, Robespierre severely wounded himself by a pistol shot in the jaw. He was guillotined on the same evening on the Place de la Révolution (now the Place de la Concorde).

Volumes 1–9 of his complete works (including his speeches) were published between 1910 and 1961, while volume 10, the final volume, was in preparation. *See* also references under "Robespierre, Maximilien François Marie Isidore de" in the Index.

ROBEY, SIR GEORGE (1869–1954), English music-hall comedian known for many years as "the prime minister of mirth," was born George Edward Wade, on Sept. 20, 1869, at Herne Hill, Kent. He made his first appearance on the professional stage in 1891 and of his numerous character roles, the most famous—the collarless cleric with the red nose, the startled and heavy black eyebrows, the indignant stare, the ribald smile—was a quite early development. He solaced London in the years of World War I in *The Bing Boys Are Here,* a jovial musical comedy, and for 15 years thereafter he toured in his own revues and with his own companies. In 1932 he was Sir Charles Cochran's choice for King Menelaus in a lavish production of Offenbach's *Helen,* and three years later he was chosen to play Falstaff in *Henry IV* (Part I). Though most of the critics decided that this was an artistic error, his performance was highly intelligent and very funny.

Robey appeared in many pantomimes and films, and in countless music-hall performances. A tireless perfectionist, he worked hard up to his retirement at the age of 80, and was knighted in 1954. He died in the same year on Nov. 29 at Saltdean, Sussex.

ROBIN, a large North American thrush (*Turdus migratorius*), one of the most familiar songbirds in the eastern U.S. Its name was derived from its resemblance to another bird, the smaller European robin (*Erithacus rubecula*), called also redbreast or robin redbreast.

American Robin.—The American robin is about 10 in. long, with brick-red breast, blackish-gray upper parts and a yellow bill. It has bold white markings around the eye, under the chin and on the tips of the outer tail feathers. Females are slightly paler, and the young have spotted breasts as in other thrushes. Most robins are highly migratory, spending the winter in flocks in the southern U.S., but a few winter as far north as southern Canada. The robin is a shy woodland bird in northern forests, but elsewhere it has adjusted so completely to man that to see a robin pull an earthworm from the ground is a sight familiar to everyone.

The nest, of vegetation and trash with a firm molded inner

ALLAN D. CRUICKSHANK FROM NATIONAL AUDUBON SOCIETY

AMERICAN ROBIN (TURDUS MIGRATORIUS)

layer of mud, is built in trees, open sheds, bridges, etc. Three to five bluish-green eggs are incubated by the female for 12 days. Both parents tend the young, which fly in 14–16 days. There are two to three broods per season.

Its song consists of caroling phrases, differing in pitch, with pauses between them—a cheerful, bubbling air. There are various call notes, harsh and scolding. Earthworms, insects, berries and some grains are taken for food. The arrival of the first robins, usually males, is looked forward to in the early spring.

European Robin.—The robin of the old world is about 5½ in. long, with brownish-orange breast and forehead, brownish-olive upper parts and a white abdomen. The young have a mottled dark brown-and-buff breast. It is a woodland bird primarily but is notably confiding toward man. Everywhere it is well known for its cocky, jaunty attitudes. It is migratory in northern Europe, but only partially so or sedentary farther south. The nest is in holes and crannies in walls, banks, trees and the like. The five to six whitish eggs are incubated 13–14 days by the female, who is fed by the male. The young fly in 12–14 days and then a second brood is reared. The bird sings almost all year, uttering high-pitched warbling phrases, and has various call notes. Food is mainly insects.

There is considerable folklore about the robin; the old-world lore that it is bad luck to kill one has been applied also to the American robin.

See David Lack, *The Life of the Robin,* rev. ed. (1947), *Robin Redbreast* (1950). (R. S. Pr.)

ROBIN HOOD, the hero of a series of ballads the earliest of which date from the 14th century, at the latest. William Langland, in the B version of *The Vision of Piers the Plowman,* usually dated *c.* 1378, mentions "rymes of Robyn Hood," and internal evidence from the earliest ballads confirms that they must have been well known by that time. Other medieval references to Robin Hood, such as that by the Scottish chronicler John of Fordun, in the work continued by Walter Bower as *Scotichronicon* (edited by T. Hearne, 1722, vol. iii, pp. 773–74), make it clear that the ballads already in circulation were the only evidence for his existence available to these writers. Numerous attempts have been made to prove that such a person once existed. The fabricated pedigree by the 18th-century antiquary William Stukeley can be dismissed, although it may have been the origin of the popular modern belief that Robin Hood was a contemporary of Richard I. It was not until J. M. Gutch's 1847 edition of the *Lytyll Geste of Robin Hode* that the more serious view was advanced that Robin might have been one of the disinherited followers of Simon de Montfort after the Evesham defeat of 1265. This suggestion was revived in *King Henry III and the Lord Edward* (1947), by Sir Maurice Powicke, who names a midland outlaw called Roger Godberd. Hood or Hod was not an uncommon name. A. L. Poole (in *From Domesday Book to Magna Carta,* 1951) and J. C. Holt (see *Bibliography*) favour Robert Hood or "Hobbehod," a Yorkshire fugitive mentioned in the pipe rolls of the late 1220s. Another Robert Hood was discovered by Joseph Hunter in the wardrobe accounts of Edward II. He suggested that this was an outlawed follower of Earl Thomas of Lancaster, one of the "contrariants" pardoned by Edward II during his visit to the north in 1323 (see *Critical and Historical Tract, no. iv,* 1852). J. W. Walker revived this theory (*Yorkshire Archaeological Journal,* 1944) and gave it further colour by pointing to a Hood family mentioned in the court records of the manor of Wakefield in the West Riding of Yorkshire, the area where some of the ballad episodes are located.

It is clear that the evidential basis for the various identifications of Robin Hood, distributed as they are over a century and a half, is very fragile. It is indeed more likely that the origins of the legend are to be found in the 13th rather than in the 14th century. It was in the earlier period that the sheriff was most prominent as the local representative of law and order and that there was the greatest resentment against the laws of the forest. It may be that one of the persons called Robert Hood was the man around whom the legend crystallized, but there is no reason to suppose that he took part in the events recounted in the ballads. The stories must be considered primarily as projections of the popular imagination, and the ballads, properly interpreted, are thus as important as a historical record of the medieval mind as if they were a record of actual events.

Although many of the well-known Robin Hood ballads are post-medieval, there is a core which can be certainly attributed to the medieval period. These are *Robin Hood and the Monk; Robin Hood and Guy of Gisborne; Robin Hood and the Potter;* and the *Lytyll Geste of Robin Hode,* which contain all the essential features of the legends, and from which can be deduced what popular aspirations are embodied in the life and death of the hero.

The most obvious feature of Robin Hood's life is that he was a rebel against authority, and the most striking episodes show him and his companions robbing and killing men who represented it. Their most frequent enemy is the sheriff of Nottingham, the principal local agent of the central government. Next come the wealthy ecclesiastical landowners, of whom the most vividly portrayed is the abbot of the Benedictine monastery of St. Mary's, York. The courtesy which characterizes Robin's treatment of the poor knight, of women, and of persons of humble status disappears when he and his followers are dealing with the sheriff and his agents (such as Guy of Gisborne). Then, too, the early ballads reveal the cruelty which is an inescapable aspect of medieval social relations. The sheriff is shot with arrows and beheaded, Guy of Gisborne's head is stuck on the end of a bow and the face mutilated. The monk and Much "the little page" (not to be confused with Much, the Miller's son, who figures in some of the stories) are beheaded. Robin is bled to death by the prioress of Kirklees. Her lover is slain and given to the dogs to eat.

Of Robin Hood's companions the one who appears most frequently as an actor with individuality is Little John. He is the subject of some of the most humorous episodes, as when he enters the sheriff of Nottingham's service disguised as Reynald Grenelefe. Another companion traditionally associated with Robin is Maid Marion, but this is a post-medieval tradition. By the 16th century the Robin Hood stories were frequently mimed as part of the May

Day games (*see* MAY) and Marion was associated with Robin, as is appropriate in a celebration which may have originated in a fertility cult. She was, however, almost certainly borrowed from the French pastoral couple, Robin and Marion, who figure in Adam de la Halle's dramatized *pastourelle* the *Jeu de Robin et Marion* (*c.* 1283). She appears in none of the medieval ballads, from which women are almost entirely absent.

Although Robin Hood's main enemy was the sheriff of Nottingham, the internal evidence of the early ballads makes it clear that the action took place most frequently in south Yorkshire. The meeting of Robin with Sir Richard atte Lee was in Barnesdale between Doncaster and Wakefield. "Reynald Grenelefe" was from Holderness. The wicked abbot was from York. The nunnery of Kirklees was between Halifax and Wakefield.

The authentic Robin Hood ballads, then, are the poetic expression of popular aspirations in the north, in a turbulent era of baronial rebellions and of agrarian discontent which culminated in the Peasants' Revolt of 1381 (*q.v.*). The theme of the free, but persecuted outlaw enjoying the forbidden hunting rights of the forest and outwitting or killing the forces of law and order would naturally appeal to both urban and rural lower classes, whether free or serf, and even to unruly elements among the landed gentry.

From the 16th century onward the essential character of the legend was distorted. The chronicler Richard Grafton, in his *Abridgement of Chronicles* (1562, p. 54), suggested that Robin was a fallen nobleman, and this was taken up by the court playwrights Anthony Munday and Henry Chettle in *The Downfall of Robert, Earl of Huntingdon* and *The Death of Robert, Earl of Huntingdon* (1601) which also identified Maid Marion as Matilda Fitz Walter. Though increasing Robin's romantic appeal, this new element deprived the legend of the social bite of the earlier ballads, and the post-medieval ballads, no doubt as a result of having lost an important original impulse, also lost much vitality and poetic value.

ROBINSON, BOARDMAN (1876–1952), Canadian-U.S. political cartoonist and painter, was born in Somerset, Nova Scotia, on Sept. 6, 1876. As a student in Paris in 1898, he was influenced by the great tradition of French political cartooning begun by Honoré Daumier. In New York City his trenchant cartoons later appeared in many newspapers and periodicals, and he affected a whole school of political cartoonists, including artists such as H. Glintenkamp, Robert Minor, William Gropper, Daniel Fitzpatrick, and Edmund Duffy. As a teacher at the Art Students League, New York City, 1919–30, and as founder and head of the Colorado Springs (Colo.) Fine Arts Centre, 1936–47, he taught many outstanding artists. Robinson also made illustrations for *Spoon River Anthology*, *The Brothers Karamazov*, *Moby Dick*, and *Leaves of Grass* and created the murals in the Department of Justice building in Washington, D.C. His remarkable gift was his calligraphic line; its searching quality inspired a new kind of political cartooning in the United States. He died in Stamford, Conn., on Sept. 5, 1952.

See Albert Christ-Janer, *Boardman Robinson* (1946). (A. W. C.-J.)

ROBINSON, EDWARD (1794–1863), U.S. biblical scholar, considered the father of biblical geography, was born in Southington, Conn., on April 10, 1794. He graduated from Hamilton College in 1816, taught mathematics and Greek there, was instructor in Hebrew at Andover Theological Seminary, and in 1826 went to Europe to study in the major German universities, returning to the U.S. in 1830. In 1837 he became professor of biblical literature at Union Theological Seminary, New York City, and left the U.S. to explore in Palestine and Syria. His *Biblical Researches in Palestine, Mount Sinai, and Arabia Petraea*, which was published simultaneously in England, Germany, and the U.S. in 1841, immediately established his reputation. *Later Biblical Researches in Palestine and the Adjacent Regions* appeared in 1856. Robinson's plans to sum up his important topographical studies in a work on biblical geography were cut short by cataract in 1862. He died in New York City on Jan. 27, 1863. *Physical Geography of the Holy Land*, including his last work as far as he had been able to carry it, was published in 1865. All of Robinson's works were based on careful personal exploration and tempered by a thoroughly critical spirit, which was possibly at times too skeptical of local tradition.

He was the author also of *Harmony of the Four Gospels in Greek* (1845) and *Harmony of the Four Gospels in English* (1846), both important in their day.

See H. B. Smith and R. D. Hitchcock, *The Life, Writings, and Character of Edward Robinson* (1863).

ROBINSON, EDWIN ARLINGTON (1869–1935), U.S. poet, known best for his narrative poems and dramatic lyrics concerning the residents of "Tilbury Town," and long narrative blank verse creations out of Arthurian and biblical materials. A descendant of the colonial poet Anne Bradstreet, Robinson was born in Head Tide, Me., on Dec. 22, 1869, and spent his boyhood and youth in Gardiner, Me., generally considered the model of "Tilbury Town." After two years at Harvard (1891–93) he moved to New York City, where he spent a few years in relative obscurity. With the award of the Pulitzer Prize for his *Collected Poems* (1921), he became a well-known poet and a subject of both critical and popular interest. He died in New York City on April 6, 1935.

Robinson's poetry falls within two general types. In his early career (from *The Children of the Night*, 1897, which included the poems from the privately printed *The Torrent and the Night Before*, 1896, to *The Man Against the Sky*, 1916), his best poetic form was the dramatic lyric (the sonnet, the quatrain, the eight-line stanza), occasionally varied (as in the title poem of *The Man Against the Sky*) by a symbolic poem of loose structure and an assertive philosophy. During these years, he perfected the poetic form for which he became so well known: the firm stanzaic structure, skilful rhyming patterns, a precise diction, combined with a dramatic instance of the human condition, usually in terms of the "Tilbury Town" pattern. Robinson is often interpreted as a "pessimist," and it is true that some of his major poems of this period treat human failures of several kinds, often culminating in suicide. In his most important philosophical expression, *The Man Against the Sky*, however, the conflict between the dark side of life and a traditional American Transcendentalism was resolved by an assertion of human value that all but removed the pessimistic grounds of its beginnings.

The second phase of Robinson's career as poet began with the publication of *Merlin* (1917); it was followed by *Lancelot* (1920), *Tristram* (1927, perhaps his most popular poem, which received the Pulitzer Prize in 1928), *Cavender's House* (1929), *Matthias at the Door* (1931), and *King Jasper* (1935). The principal distinction of these later volumes was their narrative blank verse which Robinson often managed skilfully but which was nevertheless not equal to the demands of a succession of long poems.

Barnard (1952), and E. S. Fussell (1954); C. P. Smith, *Where the Light Falls: a Portrait of Edwin Arlington Robinson* (1965). (F. J. Hn.)

ROBINSON, HENRY CRABB (1775–1867), English man of letters, whose diaries provide valuable details of social and literary life in a period of intellectual and political change, was born at Bury St. Edmunds, Suffolk, on May 13, 1775. In 1796 he settled in London, where he became a lawyer, being called to the bar in 1813 and practising on the Norfolk circuit until 1828. Having inherited a small private income in 1798, in 1800 he went to Germany, and there met Goethe, Schiller, Herder, Wieland, and Mme de Staël, who acknowledged his help in collecting material for her *De l'Allemagne* (1813), and, on returning to England in 1805, he was influential in making German literature and philosophy widely known. From 1807 to 1809 he acted as foreign correspondent for *The Times*, and he later played a part in the campaign against slavery, the agitation leading to the Dissenters' Chapels Act (1844), and the founding of London University.

Crabb Robinson's interest in men, books, and affairs, and his

good sense, good nature, and shrewd judgment, made him generally popular. He accompanied Wordsworth on several tours in Great Britain and abroad, and was a frequent visitor at Rydal Mount. He made notes of Coleridge's lectures, befriended William Blake, of whose last years his diaries provide the only firsthand account, and on visits to Italy (1829–31) stayed with Walter Savage Landor. His diaries, reminiscences, and letters, more than 100 volumes of which are preserved in Dr. Williams's Library, London, contain lively portraits of the literary figures of his time, and his correspondence with William and Dorothy Wordsworth is an important source of information on the poet's later life. He was famous also as a conversationalist and gave Sunday morning breakfast parties which rivaled those of Samuel Rogers (*q.v.*). He died in London on Feb. 5, 1867.

BIBLIOGRAPHY.—A selection from his diaries, etc., was ed. by T. Sadler as *The Diary, Reminiscences and Correspondence of Henry Crabb Robinson,* 3 vol. (1869; 3rd ed., 2 vol., 1872). Further selections were ed. by E. J. Morley as *Blake, Coleridge, Wordsworth, Lamb, etc.* (1922), *Correspondence of Henry Crabb Robinson with the Wordsworth Circle, 1808–66,* 2 vol. (1927), *Crabb Robinson in Germany, 1800–05* (1929), and *Henry Crabb Robinson on Books and Their Writers,* 3 vol. (1938). *See* also E. J. Morley, *The Life and Times of Henry Crabb Robinson* (1935); J. M. Baker, *Henry Crabb Robinson of Bury, Jena, "The Times," and Russell Square* (1937). (N. C. N.)

ROBINSON, HENRY WHEELER (1872–1945), English Baptist theologian and Old Testament scholar, who, in the austerity of his character and in his iron self-discipline and devotion to duty, represented the highest traditions of English Nonconformity, was born at Northampton on Feb. 7, 1872. After three years as a clerk, he studied at Regent's Park College, London, the University of Edinburgh, Mansfield College, Oxford, and Marburg and Strasbourg universities (1890–1900). He was Baptist minister at Pitlochry, Perthshire (1900–03), and St. Michael's, Coventry (1903–06), before being appointed tutor at Rawdon Baptist College near Leeds, becoming president of the Yorkshire Baptist Association in 1918. There he wrote the valuable textbook *The Religious Ideas of the Old Testament* (1913; rev. ed. by L. H. Brockington, 1956). From 1920 to 1942 he was principal of Regent's Park College, where his teaching and administrative gifts had full scope. It was largely through his foresight and unremitting labour that the college was transferred from London to Oxford.

Robinson's most important academic work was in Hebrew psychology (notably in his exposition of the concept of "corporate personality") and Old Testament theology. His Speaker's Lectures (Oxford), posthumously published as *Inspiration and Revelation in the Old Testament* (1946), are the prolegomena to a full-scale Old Testament theology which he did not live to write. The *Christian Doctrine of Man* (1911), *The Christian Experience of the Holy Spirit* (1928), and *Redemption and Revelation* (1942) reflect his wider theological interests. His influence on his students was deep and lasting. He died at Oxford on May 12, 1945.

See E. A. Payne, *Henry Wheeler Robinson* (1946), and list of Robinson's writings in *Studies in History and Religion, presented to Dr. H. Wheeler Robinson, M.A., on His Seventieth Birthday,* ed. by E. A. Payne (1942). (G. W. AN.)

ROBINSON, SIR HERCULES: *see* ROSMEAD, HERCULES GEORGE ROBERT ROBINSON, 1st Baron.

ROBINSON, JOHN (*c.* 1575–1625), English Nonconformist minister, "the pastor of the Pilgrim Fathers," was born about 1575 at Sturton-le-Steeple, Nottinghamshire. In 1592 he entered Corpus Christi College, Cambridge (fellow 1597), and by 1602 had taken orders, becoming a "preaching elder" at St. Andrew's, Norwich, about 1603, and in 1604 married Bridget White. His refusal to conform to the anti-Puritan canons of 1604 led to his suspension from preaching, and in 1606 or 1607 he joined the Separatist congregation at Scrooby. With them he went in 1608 to Holland, where a Separatist congregation already existed in Amsterdam. Dissension was rife among the various Nonconformist groups (*see* PURITANISM: *Stuart Puritanism*), and in 1609 Robinson, with 100 followers, moved to Leiden. As pastor of the Leiden congregation, Robinson developed a church (growing to 300 members) described by William Bradford as of such "true piety, humble zeal and fervent love towards God and his Ways [as to come nearer than any other] to the . . . pattern of the first churches."

In 1615 Robinson entered Leiden University as a student in theology, and took part in disputations with the Arminian and Calvinist professors. By 1617 he and his followers had begun to look for a more secure and permanent abode than Leiden. In July 1620 the "Speedwell" sailed, with part of Robinson's congregation, to Plymouth, from which the "Mayflower," with 35 of the Leiden contingent aboard, left for New England in September. Robinson, prevented from following, died at Leiden on March 1, 1625, and the remnant of his church was absorbed in the Dutch Reformed Church in 1658. A memorial in the Pieterskerk at Leiden, put up in 1928, refers to his having "guided and developed the religious life of the pilgrims of the Mayflower."

Robinson's writings show his humility, piety, and growth in charity from the rigid Separatism of his early *Justification of Separation from the Church of England* . . . (1610), by way of *Of Religious Communion, Private and Public* (1614), distinguishing between personal and public religious actions; to *On the Lawfulness of hearing Ministers in the Church of England* (written about 1624; published 1634). In this, he reaffirms the necessity of withdrawal from the English "hierarchical church government and ministry and appurtenances thereof," but stresses his readiness "in all outward actions and exercises of religion . . . to express . . . Christian fellowship and communion" with all "Christian brethren." But his most famous words are in his sermon of July 20, 1620, bidding those about to sail to be ready to receive anything that God may reveal to them, "For I am very confident the Lord hath more truth and light yet to break forth out of His holy Word."

Haller, *Liberty and Reformation in the Puritan Revolution* (1955). (D. M. Pa.)

ROBINSON, SIR JOHN (1839–1903), British statesman and first prime minister of Natal when the colony was granted responsible government in 1893, was born at Hull, Yorkshire. He emigrated with his parents in 1850 to Durban where his father, George Eyre Robinson, soon became the co-founder and editor of the *Natal Mercury,* a weekly newspaper. On his father's death in 1861 John Robinson took over the editorship with such success that by 1864 the newspaper was appearing three times weekly and in 1878 became a daily paper.

In 1863 Robinson was elected to the Natal Legislative Council at Pietermaritzburg (consisting of 5 official and 15 elected members), taking a leading part in its debates and becoming a consistent advocate of the cause of colonial self-government. However, a revolt by the Hlubi chieftain Langalibalele in 1873 betrayed the political immaturity of Natal, and in 1875 imperial control was tightened when Sir Garnet Wolseley, sent by the Colonial Office as governor and general commanding, strengthened the official element in the council. In 1880 Robinson again took the lead in agitating for responsible government, but the elections held on this issue in 1882, in which he was unseated, showed that he was out of touch with public opinion; as Zululand was in an unsettled condition, the colonists were not eager to assume the burden of their own defense. Returning to the Legislative Council in 1884, Robinson attended the Colonial Conference in London in 1887 and the following year represented Natal at the South African Customs Conference. He was knighted in 1889.

After the British annexation of Zululand in 1887, responsible government again became a live issue, and in 1893, supported by his former leading opponent, Harry Escombe, Robinson succeeded in getting the British government to agree to self-government for Natal. He served as prime minister from 1893 to March 1897, when failing health led to his retirement. He died at Durban on Nov. 5, 1903. His works include a novel, *George Linton* (1876), and *A Lifetime in South Africa* (1900).

ROBINSON, SIR ROBERT (1886–), British chemist who was awarded the Nobel Prize for chemistry in 1947 for his

research on the alkaloids, was born at Bufford, near Chesterfield, Derbyshire, on Sept. 13, 1886, and educated at Fulneck School, Leeds, and the University of Manchester, where he obtained the degree of D.Sc. in 1910. He was professor of pure and applied organic chemistry in the University of Sydney, New South Wales (1912–15), and then occupied chairs of chemistry successively in the universities of Liverpool (1915–21), St. Andrews (1921–22), Manchester (1922–28) and at University College, London (1928–30). He was appointed to the Waynflete chair of chemistry in the University of Oxford in 1930 and retired in 1955. His researches dealt not only with the structure and synthesis of many organic bodies, but also with the theory of mesomerism (*see* RESONANCE, THEORY OF). His studies of the structure of plant pigments called anthocyanins led him to extend his investigations to another group of plant substances, the alkaloids; his work on the details of alkaloid molecular structures led to the successful production of certain antimalarial drugs. Many honours were conferred on him, including the Copley Medal of the Royal Society in 1942. He was knighted in 1939 and received the Order of Merit in 1949. He was president of the Royal Society (1945–50) and of the British Association for the Advancement of Science (1955).

(D. McK.)

ROBOT, a term popularly used to describe either a mechanical or electromechanical device with humanlike actions or a person whose repetitive and mechanical actions resemble those of a machine. Derived from the Czech word *robota* ("work"), the term has long been used in many languages. In layman's terminology, robot has, to a large extent, replaced the more classical terms automaton, meaning contrivances which simulate motions of animal life (Gr. *autos*, "self," and *mao*, "seize"), and androides, which refers to representations of the human figure and actions.

Modern use of the word robot stems from the play *R.U.R.* (Rossum's Universal Robots), written in 1920 by the Czech author Karel Čapek, in which society was described as depending on mechanical workers called robots able to do any kind of mental or physical work. In the play the robots, having developed intelligence and a spirit of revolt, turn on their human employers and finally exterminate them.

Early Robots.—The construction of mechanical men and animals has captivated the imagination of man since antiquity. In 400 B.C., Archytas of Tarentum is said to have made a wooden pigeon that could fly, and during the Middle Ages numerous instances of the construction of automatons were recorded. The German astronomer Johann Müller (Regiomontanus) is said to have made an iron fly that would flutter around the room and return to his hand, and also to have fabricated an eagle that flew before the emperor Maximilian when he entered Nürnberg. Many curious Swiss-built toys, such as flying and singing birds, are frequently displayed in industrial exhibitions. Wolfgang von Kempelen's famous chess player for many years astonished and puzzled Europe, and during the latter part of the 19th century John Nevil Maskelyne exhibited his robots, "Psycho" (who played cards) and "Zoe" (who drew pictures), at the Egyptian Hall, London. (*See* CONJURING.) These robots were actually hoaxes, although the mechanical contrivances for concealing the real performer were exceedingly ingenious.

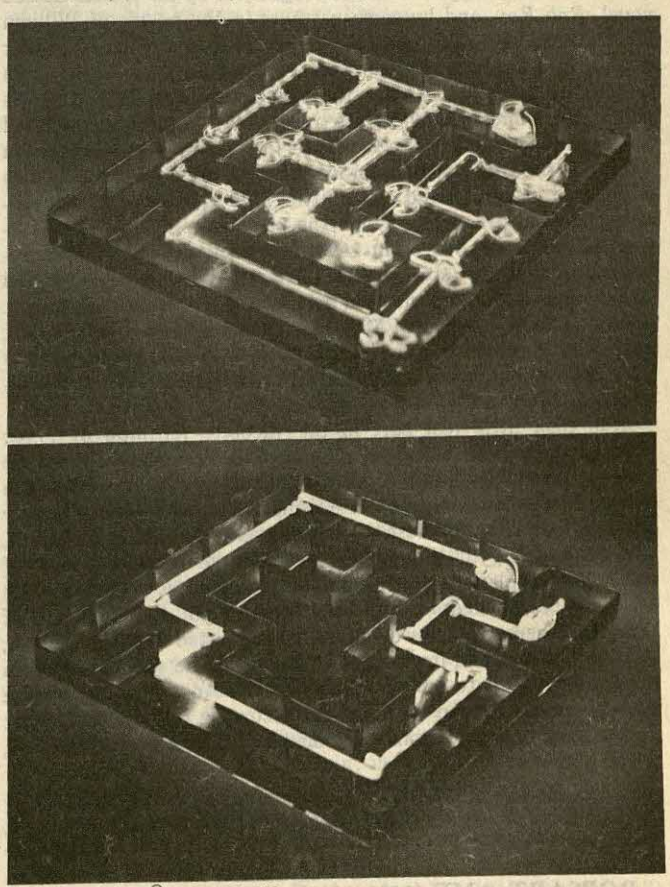
Modern Robots.—In the 20th century a variety of machines which, when operated by remote electrical or mechanical control, perform many of the actions of a human being have been built. The "Voder," demonstrated in 1939 at Philadelphia, Pa., had "vocal cords" of vacuum tube circuits that reproduced vowels, consonants, and monosyllables. The operator, using a keyboard and a foot pedal, produced whole sentences of human speech from the mechanism. A more directly useful remote-controlled machine has been built to perform jobs in dangerous radioactive areas. It moves about and is equipped with arms and hands that can grip various objects. The actions of the machine are controlled by an operator stationed at a console at a safe distance from the radioactive sources and the machine's entire behaviour is monitored on a television screen.

Modern developers of robots endeavour to simulate, however crudely, the sensory, locomotor, memory, and learning functions of animals and human beings. Technological developments of the 20th century have contributed exciting possibilities in this regard. Sensors, such as light-sensitive cells, microphones, contact switches, and chemically sensitive materials, permit very rough simulation of the senses of sight, hearing, touch, and taste or smell. Vacuum tube and transistor circuits serve as an electronic nervous system to alter suitably the signals detected by the sensors and to convey these signals to data-processing or memory devices composed of relays, vacuum tubes, or magnetic-switch circuits. The data-processing and memory devices in turn send commands to motors that act as mechanical muscles. Many of these electronic devices are built into the robot animal.

A tortoise-shaped robot, named *Machina speculatrix*, is a more complex type. It is attracted by moderate light and repelled by intense light or material objects; it is thus able to navigate safely across a room despite the presence of obstacles in its path.

Perhaps the greatest challenge to robot designers is that of reproducing the higher faculties, such as learning capabilities, of animals and human beings. In one such attempt the tortoise was modified to make it responsive to a reflex-conditioning process. Patterned after the conditioned-reflex experiments of the Russian physiologist Ivan Petrovich Pavlov, this robot couples a specific stimulus (light) with an unrelated stimulus (sound) so that the latter evokes, after a conditioning period, the same response as the specific stimulus. (*See* CONDITIONING.) The robot has the basic capability of moving in response to a light. Initially it will not respond to sound alone. However, its circuits are arranged so that it can be "conditioned" to associate a sound with light. Thus, after a conditioning period during which a whistle is blown each time a light is flashed, the machine, through its electronic reflexes, is conditioned to associate sound with light and will respond thereafter to sound alone.

Theseus, the mouse, is an example of a machine that learns



GALE JOEL—"LIFE," © 1952 TIME, INC.

THESEUS THE MOUSE, A MACHINE THAT LEARNS

(Top) In his first try to reach his goal, Theseus wanders through the maze encountering many dead ends. (Bottom) In his second try, Theseus "remembers" the turns that led nowhere and goes directly to his objective. The light attached to his back indicates his movements during each try

through use of its computer-type memory circuits. When first inserted in a maze and set in motion, the robot wanders aimlessly in and out of the corridors, encountering many dead ends en route. Eventually it finds its way to the finish point. In going through the maze the first time, the robot circuits "remember" those moves that lead nowhere. Thus, in traversing the maze the second time the robot travels directly to the finish point without making any false moves. If it is placed in the middle of the maze after having traversed it once, the robot wanders aimlessly until it recognizes the correct path and then follows it directly to the finish point.

Large-scale electronic digital computers have opened up new possibilities for simulating the learning processes of human beings. These machines are easily programmed to play games of skill such as ticktacktoe, checkers, and chess. Moreover, through their ability to recognize patterns, they analyze the playing habits of their opponents and thus improve their playing ability in successive tries. By means of this learning process, chess-playing computers have been known to defeat the person who supplied the original playing instructions to the machine.

To develop robots with increasingly complex behavioural abilities, scientists strive to achieve a better understanding of the processes of thought, along with a better understanding of the cerebral mechanisms and nervous systems of animals and human beings. Corresponding technological refinements contribute better simulations of complex behavioural functions.

ROB ROY (1671–1734), the nickname of Robert Macgregor, a noted Highland outlaw whose reputation as a Scottish Robin Hood has been exaggerated and strengthened by Sir Walter Scott's novel, *Rob Roy*, and by some passages in the poems of William Wordsworth. Rob's father, Donald Macgregor, a younger brother of the chief of the Macgregor clan, received a commission from the former king James after the revolution of 1688, but Rob's politics were uncertain and his activities may as safely be ascribed to brigand tendencies as to idealistic Jacobitism. As a grazier on a farm on the Braes of Balquhidder (Perthshire), he probably also engaged in blackmail and cattle lifting, old and then still honourable Highland practices. When the penal laws against the Macgregors were reintroduced in 1693, Rob took the name of Campbell. His lands lay between those of the rival houses of Argyll and Montrose and for a time he used that rivalry for his own advantage. James Graham, 1st duke of Montrose, finally entangled him in debt and in 1712 ruined him by legal but unscrupulous means; thereafter Rob embarked upon a career of brigandage chiefly at the expense of Montrose.

Rob took little real part in the Jacobite rebellion of 1715; distrusted by both sides, he plundered each impartially in the true "cateran" tradition of the Highland brigand bands, which was an element in all the Jacobite risings. He was treated leniently after the rebellion, because of the intercession of John Campbell, 2nd duke of Argyll. But he did not mend his ways, and some of his boldest exploits against Montrose occurred at this time. He was only reconciled to him in 1722 through the influence of Argyll. Thereafter, however, he was arrested by the English, sent to London, and imprisoned in Newgate; he was pardoned in 1727 when about to be transported to Barbados. In his old age Rob became a Roman Catholic, but according to his own account for no very devout reasons. He died at Balquhidder on Dec. 28, 1734.

ROBSART, AMY (1532–1560), wife of Lord Robert Dudley, afterward earl of Leicester, who has often been suspected of her murder, was the daughter of Sir John Robsart of Norfolk. She married Lord Robert on June 4, 1550. When Elizabeth I became queen in 1558, Lord Robert rose rapidly in her favour and many believed that she might marry him if he were free. His wife did not go to court with him, though he visited her and corresponded with her in the years 1558 and 1559. Early in 1560 she moved into Cumnor Place, near Oxford. There, on Sept. 8, 1560, she was found with her neck broken at the foot of the stairs. Her husband's enemies, then and later, suspected him of murder, but a coroner's jury returned a verdict of accidental death, and the latest research indicates that she may have died of a "spontaneous fracture" of the neck resulting from cancer of the breast.

ROC (more correctly RUKH), a gigantic fabulous bird, said to carry off elephants and other large beasts for food. It occurs in the *Thousand and One Nights* (*q.v.*), especially in the stories of Sindbad the Sailor (*q.v.*). Marco Polo (*q.v.*), who also refers to it in describing Madagascar and other islands off the East African coast, reports that the Great Khan "sent to those parts to enquire about these curious matters," and was brought what was claimed to be a rukh's feather, which may really have been a frond of the *Raphia* palm.

The rukh found its way into Arabic and Persian medieval scientific literature under the names of *'anqā'* (Arabic) and *simurgh* ("30 birds"; Persian). (See *The Zoological Section of the "Nuzhatu-l-Qulūb" of Hamdullāh al-Mustaufī al-Qazwīnī*, edited, translated, and annotated by J. Stephens, for the Royal Asiatic Society, 1928.)

Smithers (1894), vol. iv, pp. 84–85, 357–360, 556, vol. x, pp. 136–137; *The Book of Ser Marco Polo*, trans. and ed. by Sir Henry Yule, 3rd ed., rev. by H. Cordier (1903), vol. ii, pp. 412–421 and 596–598; R. Wittkower, "Marco Polo and the Pictorial Tradition of the Marvels of the East," in *Oriente Poliana*, pp. 157–159 (1957).

ROCAMADOUR, a village of southwestern France, in the *département* of Lot, 40 mi. (64 km.) NNE of Cahors by road. Pop. (1962) 165. It is most strikingly situated, its buildings rising in stages up the side of a cliff on the right slope of the gorge of the Alzou. The lower town consists of a long street with five fortified gateways and a restored 15th-century town hall. Flights of steps ascend to the churches halfway up the cliff: the Chapelle Notre-Dame, containing the wooden figure of the black Madonna, a basilica (11th century), and six other chapels. On the cliff stands the 14th-century castle with a fine view over the valley. Rocamadour owes its origin, according to tradition, to St. Amadour (or Amateur), who chose the spot as a hermitage for his devotions to the Virgin Mary, and it became a place of pilgrimage in the early Middle Ages. Jacques Cartier upon landing in the New World prayed to the Virgin of Rocamadour; a chapel in Quebec records the event. Rocamadour is near the Paris-Toulouse railway (via Capdenac). It is a much visited shrine and a centre for tours by motor coach. The chief occupations are sheep breeding and the sale of truffles, nuts, and lavender. (JE. R.)

ROCH (ROCK, ROCCO), **SAINT** (1350?–1378/79?), was venerated in France and Italy by the early part of the 15th century, but there is no authentic history of his life. According to surviving stories about him (chiefly legendary), he was born at Montpellier, Fr., about 1295, but modern scholarship favours 1345 or 1350 for the year of his birth. The stories relate that on the death of his parents in his 20th year he gave all his substance to the poor and went on a pilgrimage to Rome. During an epidemic of plague in Italy, he tended the sick at Acquapendente, Cesena, and Rome, and effected miraculous cures by prayer and simple contact. After similar ministries at Piacenza he himself fell ill. He was expelled from the town and withdrew into the forest, where he would have perished had not a dog supplied him with bread. On his return to Montpellier he was arrested as a spy and thrown into prison, where he died (traditionally 1327; more probably 1377 or 1378/79), having previously obtained from God this favour—that all plague-stricken persons invoking him be healed. His cult spread through Spain, France, Germany, Belgium, and Italy, and there is even a trace of it in England. A magnificent church was

built in his honour at Venice, where his relics are still venerated. His feast day is Aug. 16.

(H. DE.; X.)

ROCHA, a department of Uruguay on the Atlantic coast bordering Brazil, and also the departmental capital. The department has a population of 100,202 (1962 est.) in a territory of 4,281 sq.mi. (11,088 sq.km.). Its coastline of sand beaches increasingly attracts vacationers, as the development of Uruguayan ocean resorts continues to move eastward from Montevideo. The colonial fortress of San Miguel has been reconstructed as a historical site. Inland, Rocha is noted for its cattle and sheep ranches. Swine and poultry are also raised. The city of Rocha (pop. [1963] 19,484) is the centre of an agricultural area producing corn, wheat, and sunflower seeds. (M. I. V.)

ROCHAMBEAU, JEAN BAPTISTE DONATIEN DE VIMEUR, COMTE DE (1725–1807), French general who commanded a French army that helped the American colonists defeat the British at Yorktown, was born at Vendôme (Loir-et-Cher) on July 1, 1725. He was educated at the local college and at the Jesuit school of Blois. Entering a cavalry regiment, he served in Germany in the War of the Austrian Succession, attaining the rank of colonel. During the Seven Years' War he distinguished himself in the Minorca expedition, fought in Germany, and in 1761 became a brigadier general and inspector of cavalry.

Rochambeau was appointed governor of Villefranche-en-Roussillon in 1776, and in 1780 was put in command of the French troops destined for America. With 5,500 soldiers he landed at Newport, R.I., on July 11 and placed himself under Washington's orders. He remained inactive almost a year, however, waiting for the rest of his force (which never came) and refusing to abandon the French fleet that was blockaded in Narragansett Bay by the British. At last, in June 1781, Rochambeau's force broke camp, joined Washington on the Hudson River, and in August made a swift descent on Virginia. Joined by the troops under Lafayette that were already there, the allies laid siege to Cornwallis in Yorktown and forced his surrender on Oct. 19.

Rochambeau's tact and ability made an excellent impression on the Americans. He remained in Virginia for another year and then embarked for France in January 1783. The king appointed him commander of Calais and later of the Alsace district. During the French Revolution he commanded the Northern Military District and was created a marshal of France in December 1791. Arrested during the Terror, he narrowly escaped the guillotine, but Napoleon subsequently pensioned him. He died at his château on May 10, 1807.

(H. H. P.)

ROCHDALE, a county and parliamentary borough of Lancashire, Eng., 11 mi. NNE of Manchester by road. Pop. (1961) 85,787. Area 14.9 sq.mi. The town lies at the foot of a western spur of the Pennines and at the junction of the Spodden with the Roch, which latter flows through the town (the central part has been covered in). The moribund Rochdale Canal also passes through the town. The manufacture of cotton, woolen, and rayon materials are the main industries, and there are engineering, asbestos, rubber, electrical, and other works. Rochdale has an art gallery, a museum, a repertory theatre, and five parks in addition to Hollingworth Lake (117 ac.) 3½ mi. NE.

Rochdale was the birthplace of the co-operative movement, the Rochdale Pioneers' Equitable Society having been founded there in 1844. The first shop, in Toad Lane, has been restored to its original appearance. A statue of John Bright (1811–89) recalls the connection of the statesman's family with Rochdale.

Rochdale was incorporated in 1856, but the parliamentary borough has returned one member since 1832. The county borough was created in 1888 and extended in 1933.

Rochdale (Recedham, Rachedam, Rachedal) takes its name from the river on which it stands. A Roman road passed the site, and a Saxon castle stood in Castleton. During Edward the Confessor's reign most of the land was held by Gamel the Thane, but after the Conquest the manor came into the hands of Roger de Poictou, from whom it passed to the Lacys and became merged in the duchy of Lancaster. From 1462 to 1625 the crown leased it to the Byron family. In 1625 Charles I conveyed the manor in trust, and in 1638 it was sold to Sir John Byron, afterward Baron Byron of Rochdale, whose descendants held it till 1823 when it was sold to the Deardens. Henry III (1240–41) granted to Edmund de Lacy the right to hold a weekly market on Wednesday and an annual fair on the feast of SS. Simon and Jude (Oct. 28).

ROCHEFORT, HENRI (properly VICTOR HENRI, MARQUIS DE ROCHEFORT-LUÇAY) (1831–1913), one of the most effective of French polemical writers, first for the extreme left, then for the right, was born in Paris on Jan. 31, 1831. Employed at first in the municipal administration of Paris (1851–61), he made a name as a journalist, novelist, dramatist, and author of vaudevilles, with a genius for satire. In 1868 he founded the weekly *La Lanterne*, with himself as editor. His abusive articles against the Second Empire led to the paper's suppression after its 11th issue; he himself was fined and sentenced to one year's imprisonment, but escaped to Belgium. The paper was then published in Brussels and smuggled into France, being also circulated in English, Spanish, Italian, and German editions. The violence of Rochefort's polemics involved him in four duels.

Rochefort was elected to the Corps Législatif by a Paris constituency in 1869. Arrested again, he was released when the Second Empire fell in September 1870 and became a member of the Government of National Defense. His open support of the Commune (*q.v.*) of Paris led to his resignation from the National Assembly and to his condemnation under military law. Transported to New Caledonia in 1873, he escaped after four months. The amnesty of 1880 enabled him to return to France.

After putting his powerful invective, in *L'Intransigeant*, at the service of the more extreme Radicals and Socialists, Rochefort became an outspoken supporter of Gen. Georges Boulanger (*q.v.*) and, in 1889, had to flee from France. Sentenced *in absentia* to imprisonment for his political activities, he returned to France only in 1895. The collapse of Boulangism led him to support the Socialists, but he again swung over to the right as soon as the Dreyfus affair opened in 1894 and belaboured the leaders of the Dreyfusards. He left *L'Intransigeant* in 1907, and wrote for the conservative *La Patrie*. Rochefort, who had also published an autobiography, *Les Aventures de ma vie* (5 vol., 2nd ed., 1896), died at Aix-les-Bains on June 30, 1913.

See A. Zévaès, *Henri Rochefort le pamphlétaire* (1946) and N. Roubaud, *Henri Rochefort intime* (1954).

ROCHEFORT, a town of western France, headquarters of an *arrondissement* in the *département* of Charente-Maritime, lies on the Charente River, 10 mi. (16 km.) from the sea, and 19 mi. (30 km.) SSE of La Rochelle. Pop. (1962) 26,490.

Originally Rocafortis, a fort built at the mouth of the Charente to resist the Normans, it was under the seigneurs of Rochefort in 1047. Philip the Fair acquired it early in the 14th century, and later, after the English had left Saintonge and Aunis, it was again taken over by Charles V. During the Wars of Religion it frequently changed hands. Jean Baptiste Colbert, under Louis XIV, constructed the port and arsenal there in 1665 on a grand scale. The ramparts, designed by Sebastien Vauban, have been replaced by gardens, and there is now little left of the fortifications. At the town's centre is the Place Colbert, with the Hôtel de Ville and an 18th-century monumental fountain; in the Rue Pierre Loti stands the house where Loti, the writer, was born; the Place de La Galissonnière is named after the admiral who fought Adm. John Byng at Mahón in 1756; and the Hôtel de Cheusses contains the naval museum, with ship models, figureheads, and the capstan of the old "Implacable" (built at Rochefort as the "Duguay-Trouin") which was returned to Rochefort by Britain. Also of note are the Porte du Soleil, a fine gateway to the old arsenal; the Church of St. Louis, with Corinthian columns; the Marine Hospital; and the Hôtel de la Marine, built on the site of the old citadel, and naval

headquarters since the 18th century. The Hôtel Hèbre de Saint Clément (18th century) now houses the municipal library and the museum of fine arts.

Lafayette's second voyage to North America was in the "Hermione," which sailed from Rochefort on March 10, 1780. Napoleon spent his last few days on the French mainland at Rochefort before moving to the nearby Île d'Aix, where he surrendered to the British on the "Bellerophon" on July 15, 1815.

Rochefort is an important air force centre and has a mechanics' school and an aircraft construction factory. There are extensive coal and timber yards and important exports and imports of timber. Rochefort's dairies are renowned for their cheese, butter, and cream. The hot-water artesian wells, rich in iron content, are well known. The town, lying on the Nantes-Bordeaux road and railway, is the tourist centre for Charente-Maritime.

(C. C. Me.)

ROCHELLE, LA, an Atlantic seaport city of France, capital of the *département* of Charente-Maritime and seat of a bishopric, is 90 mi. (145 km.) S.E. of Nantes on the Bordeaux railway. Pop. (1962) 65,581. It stands on an inlet between the Pointe des Minîmes and the Pointe de La Pallice sheltered by the Île de Ré and the Île d'Oléron.

The medieval town has left almost no trace, but there are some 14th- and 15th-century Gothic reminders of La Rochelle's powerful and prosperous days. These include the remains of the fortified port with its three famous towers of St. Nicolas, la Chaîne and la Lanterne; the belfry and wrought ironwork of the church of St. Sauveur; the crenellated outer wall of the Hôtel de Ville; and the 14th-century tower, sole remnant of the old church of St. Barthélemy, which stands beside the 18th-century cathedral. The most important and characteristic architecture, however, is of the 16th and early 17th centuries, as seen in certain streets of arcaded houses, with gargoyles and allegorical figures carved on their facades and pedimental windows; *e.g.,* Grande-Rue des Merciers leading to the market place. The Hôtel de Ville (*c.* 1595–1606), the private dwelling known as Maison Henri-Deux, and the houses of Nicolas Venette and Jean Guiton also date from the Renaissance. The prosperity of the early 18th century was reflected in further fine buildings: the Hôtel de la Bourse (now the chamber of commerce); the former bishop's palace (now the city library and art museum); the Hôtels d'Orbigny and Fleuriau (now containing regional history, natural history and other collections). Nineteenth-century developments of the fishing port and the port of La Pallice led to an expansion of the town. A green belt (Parc Charruyer) was laid out on the west side of the town on the site of old fortifications, and promenades were built along the front. Residential districts were established there, while beyond the green belt populous working-class areas emerged, such as the large Port-Neuf zone between La Rochelle and La Pallice, which is now a modern suburb. Development continued through the 20th century and expansion was particularly rapid after 1946, when many local industries and commercial enterprises were started and numerous schools built.

There are three main road and rail routes out of La Rochelle: to Nantes via La Roche-sur-Yon; to Paris via Niort and Poitiers; to Bordeaux via Rochefort. After World War II a project was considered for a routeway to Switzerland in connection with the port extensions at La Pallice.

La Rochelle's chief importance is as a fishing port. The harbour is one of the safest on the coast, with an outer part and two inner basins. Around the basins are railway tracks, a gas-oil pipeline, refrigeration plant, ship repair yards and a slipway. Nearby stands the fish market, one of the largest and most modern in France. The fishing and trawling fleet numbers about 200 vessels. La Rochelle, however, is inaccessible to large ships. The commercial port of La Pallice, lying 3½ mi. away, is a deep-water port constructed 1881–90 to cope with the increased size of vessels. Since then it has been several times enlarged and is equipped with a mole built out to sea and connected with the mainland by a 1,225-yd.-long causeway. It has railway sidings, a refrigeration plant, a grain silo and gasoline storage tanks, and can accommodate the largest ships. By the 1960s a project for large deep-water docks was under way. The presence of the two ports has attracted both industry and trade to La Rochelle. There are shipbuilding yards, sawmills, chemical industries, sardine and tunny canneries, and petrol refineries. La Pallice imports coal, grain, dried fish, nitrates, pyrites, jute, petroleum, gasoline, wood pulp and phosphates. Exports include wines and cognac. La Rochelle, through La Pallice, trades regularly with South America, England, Scandinavia and the far east.

La Rochelle succeeded Châtelaillon as capital of Aunis in the 12th century. Captured by Louis VIII in 1224, the town was restored to the English in 1360. France regained it when Bertrand Du Guesclin reconquered Saintonge in 1371. Favoured first by the Plantagenets and then in the 13th century by the kings of France, La Rochelle became one of the leading French seaports until the 16th century. During the Reformation it was a centre of Protestantism and suffered several sieges. After the massacre of St. Bartholomew, La Rochelle was unsuccessfully besieged (1572–73) by the Catholic army; under Louis XIII it again supported the Huguenots. In 1628 came the famous attack by Richelieu's forces; the city, led by the mayor Jean Guiton, held out until all its ammunition and food supplies were exhausted.

The subsequent development of trade with France's American possessions in the 18th century restored La Rochelle to its former prosperity. However, when the Edict of Nantes was revoked in 1685 it was deprived of several thousand of its citizens, some of whom went to America and founded (1688) New Rochelle, N.Y. This, coupled with France's loss of Canada, and the upheavals of the Revolution followed by the wars of the First Empire led to the city's decline in commercial importance. World Wars I and II again retarded its natural growth. As a German submarine base during World War II, the town was subjected to heavy Allied bombing. Its mayor Léonce Vieljeux suffered death at German hands for his opposition to the occupying authorities.

After 1945 the fishing port re-established its activities, and by 1950 the war-damaged La Pallice was completely restored, the city as a whole regaining its standing as an important Atlantic port.

(G. Bi.)

ROCHESTER, JOHN WILMOT, 2nd Earl of (1647–1680), English poet, wit, and courtier, whose reputation as a leader of Charles II's "merry gang" has somewhat obscured his gifts as a lyrical and satirical poet, was born at Ditchley Manor House, Oxfordshire, on April 10, 1647. He was the son of Henry Wilmot, 1st earl of Rochester, a distinguished Cavalier general, whom he succeeded in 1658. Educated at Burford grammar school and at Wadham College, Oxford, he received his M.A. in September 1661. Charles II, probably out of gratitude to the 1st earl, who had helped him to escape after the Battle of Worcester (1651), gave the young Wilmot an annual pension of £500, and appointed Sir Andrew Balfour, a Scottish physician, as his tutor. They traveled on the continent for three years, visiting France and Italy, and were back in England by Christmas, 1664. He then became a leading figure in the famous group called "the merry gang" at court. He was imprisoned for trying to abduct the beautiful heiress Elizabeth Malet in 1665. On his release he volunteered for the navy and served with distinction in the war against the Dutch. He married her on Jan. 29, 1667, and in March he was appointed a gentleman of the bedchamber to Charles II.

Rochester became known as one of the wildest debauchees at the Restoration Court; the hero of numerous escapades and the lover of various mistresses, among whom the most notable was the actress Elizabeth Barry, whom he is said to have trained for the stage himself. He was banished from the court several times but was always recalled by the king, who delighted in his conversation. In 1673 John Dryden dedicated to him his comedy *Marriage-à-la-Mode* in complimentary terms, acknowledging his help in writing it. Soon after, however, the two poets quarreled. Dryden attached himself to Rochester's enemy, Lord Mulgrave, and took offense at the outspoken criticism of his poetry in Rochester's poem, "An Allusion to Horace the 10th Satyr of the 1st Book," but there seems no foundation for the story that Rochester was responsible for the cudgeling of Dryden in Rose Alley, Covent Garden, in December 1679. Nor is it true, as has often

been stated, that Rochester was always a capricious or tyrannical patron of men of letters. He befriended the young schoolmaster poet John Oldham (*q.v.*) generously, and Oldham's elegy on him shows genuine affection for the man and admiration for the poet.

In spring 1675 Rochester was appointed ranger of Woodstock Forest, and the ranger's lodge at Woodstock became his favourite place of retirement, where much of his later poetry was written. His health was declining in the late 1670s and his thoughts were turning to serious matters. His correspondence with the deist Charles Blount (dated 1679–80) shows a keen interest in philosophy and religion, further stimulated by his friendship with the Scottish priest Gilbert Burnet (*q.v.*), later bishop of Salisbury, whom he met in October 1679. In the winter of 1679–80 he entered into a series of discussions on religious subjects with Burnet, who recorded them with admirable vividness and fidelity in *Some Passages of the Life and Death of John, Earl of Rochester* (1680). In spring 1680 he became seriously ill and on June 29 experienced a religious conversion, followed by a recantation of his past life when he ordered the burning of "all his profane and lewd writings." Burnet visited him at the ranger's lodge at Woodstock on July 20, 1680, and he died there on July 26. When his son, Charles Wilmot, died a year later, the title lapsed, but was revived in 1682 for Lawrence Hyde.

Rochester was undoubtedly the most considerable poet among the Restoration wits. A few of his love songs have a passionate intensity and a crystalline purity of form that recalls the best work of Burns and Heine:

> Absent from thee I languish still,
> Then ask me not, when I return?
> The straying Fool t'will plainly kill,
> To wish all Day, all Night to Mourn.
>
> *Dear;* from thine Arms then let me flie,
> That my Fantastic Mind may prove
> The Torments it deserves to try,
> That tears my fixt Heart from my Love.

He is also one of the most original and powerful of English satirists. His "History of Insipids" is a devastating attack on the government of Charles II and his "Maim'd Debauchee" has been rightly described as "a masterpiece of heroic irony." "A Satyr Against Mankind" anticipates Swift in its scathing denunciation of rationalism and optimism and the contrast which it draws between human perfidy and folly and the instinctive wisdom of the animal world:

> Be Judge your self, I'le bring it to the test,
> Which is the basest Creature Man or Beast?
> Birds feed on Birds, Beasts on each other prey,
> But savage Man alone does Man betray.

His single dramatic work is the posthumous *Valentinian*, a remarkable attempt to rehandle a tragedy of Fletcher, which contains two of his finest lyrics. It was published, with an interesting introduction by his friend Robert Wolseley, in 1685. His letters to his wife and to his friend Henry Savile are among the best of the period and show an admirable mastery of easy, colloquial prose.

BIBLIOGRAPHY.—*Editions:* A collection, *Poems on Several Occasions by the Right Honourable the E. of R.* (1680), published shortly after Rochester's death and obviously designed for readers interested in pornography, contains, besides authentic poems, much that is not by Rochester. A facsimile edition was published with a bibliographical introduction by J. Thorpe (1950). J. Tonson published an edition of *Poems on Several Occasions* with *Valentinian* and the amusing prose skit, *Alexander Bendo's Bill* (1691). *Familiar Letters* was published in 1697. The 18th-century editions of the poems have little critical value and contain much spurious material. Modern editons are *The Collected Works of John Wilmot, Earl of Rochester*, ed. by J. Hayward (1926); *Poems by John Wilmot, Earl of Rochester*, ed. by V. de S. Pinto (1953; 2nd rev. ed. 1964); a valuable edition of *The Rochester-Savile Letters*, by J. H. Wilson (1941).

Biography: J. Prinz, *John Wilmot, Earl of Rochester* (1927); C. Williams, *Rochester* (1935); V. de S. Pinto, *Enthusiast in Wit, a Portrait of John Wilmot, Earl of Rochester, 1647–1680* (1962).

(V. DE S. P.)

ROCHESTER, LAWRENCE HYDE, EARL OF (1642–1711), English statesman who held offices under Charles II, James II, and Queen Anne, was born in March 1642, the second son of Edward Hyde, 1st earl of Clarendon. His sister Anne married James, duke of York (later James II), and Rochester therefore became uncle of Mary II and of Queen Anne.

Elected to Parliament for Newport in Cornwall (1660), Hyde sat for the University of Oxford (1661–79) and held office as master of the robes (1662–75). In 1667 he joined his brother Henry, afterward 2nd earl of Clarendon, in a vain defense at their father's impeachment, and on Clarendon's flight they shared a temporary disgrace. Hyde was sent on a diplomatic mission to Poland and Vienna in 1676 and participated in the Congress of Nijmegen in 1678. He was made first lord of the treasury and a privy councillor in 1679. He opposed the bills designed to exclude the duke of York from the succession, and was created Viscount Hyde of Kenilworth in 1681 and earl of Rochester in 1682. Although he collaborated in Charles II's subsidy negotiations with Louis XIV and furthered the Tory reaction of 1682 to 1685, Rochester was "kicked upstairs" as lord president of the council by Charles II in 1684. James II appointed him lord treasurer in 1685, but he was displaced in 1687. As a high Tory Anglican he could support only Mary's claim at the Revolution of 1688, and her husband William III did not favour him. Under Anne, Rochester held office only briefly, as lord lieutenant of Ireland (1701–03) and as lord president of the council (1710–11). In his last years he occupied himself with the publication of his father's historical works and he died in London on May 2, 1711.

The correspondence of Rochester with his brother Henry was published with notes by S. W. Singer, two volumes (1828).

See K. Feiling, *A History of the Tory Party, 1640–1714* (1924).

(H. G. Ro.)

ROCHESTER, a city and municipal and parliamentary borough of Kent, Eng., on the Medway River, 31½ mi. ESE of Hyde Park corner, London; it adjoins Chatham. Pop. (1961) 50,143. Area 5.9 sq.mi. Its situation on the Roman way from the Kentish ports to London, as well as at a Medway crossing, gave Rochester (Durobrivae; Hrofaecaestrae and Hrofi *c.* 730) an early importance. It was a walled Romano-British town, and the original bridge across the Medway (Durobrivae, an old British word probably meaning "stronghold bridge") probably dated from that period. The church of St. Andrew was founded by King Aethelberht, who also made Rochester a bishop's see. It was a royal borough in the time of William I, who built a castle there, probably on Boley Hill. Richard I granted the citizens quittance of *passagium* from crusaders in the town of Rochester in 1189. In 1227 Henry III granted them the city, a guild merchant, the right to be impleaded only within the city walls, and other liberties. These charters were confirmed by subsequent sovereigns down to Henry VI, who in 1446 incorporated the city and granted it the power of admiralty and many privileges. Charters were granted in later reigns down to Charles I, whose charter of 1629 remained the governing charter until 1835. Rochester returned two members to Parliament from Edward I's time until 1885, one from then until 1918, two from 1918 to 1950; one from then on.

The cathedral church of St. Andrew was originally founded by St. Augustine in 604, for whom Aethelberht built the church. It was partly destroyed by the Danes, but was rebuilt by Bishop Gundulph (1077–1108). Gundulph or Gundulf established Benedictine monks there. Bishop Ernulf (1115–24) completed and also renovated the church. The Norman west front was built about 1125–30, and about 1352 a low central tower was built, to which a spire was added in the next century. The ruins of Gundulph's tower stand detached from and are earlier than the church; it was built by Bishop Gundulph probably as a defensive work for the eastern boundary of the city. The library attached to the modern chapter house contains, among various relics, the *Textus Roffensis*, being records of the cathedral compiled in the time of Bishop Ernulf.

On the eminence overlooking the right bank of the river are the remains of a Norman castle, part of which was built by Bishop Gundulph at the order of William Rufus in the 11th century. The castle was besieged by King John, by Simon de Montfort in the reign of Henry III, and by the followers of Wat Tyler. It was repaired by Edward IV, but soon afterward fell into decay, al-

though the massive keep still stands. It is a quadrangular four-storied structure, flanked by turrets, with a height of 113 ft. Remains of the 13th-century walls which once surrounded the city also exist. Charles Dickens lived at Gad's Hill, above Strood, to the northwest. At Borstal, southwest of Rochester, was a large convict prison where early experiments on the educational treatment of delinquent boys between the ages of 16 and 21 were carried out, which resulted in the Borstal system (*q.v.*).

Among the principal buildings in the city are the guildhall (1687), the Richard Watts' almshouses (founded in 1579), and the almshouse of St. Catherine (built 1805), which originated in 1316 as a leper's hospital. An Elizabethan mansion was acquired by the corporation for a museum as a memorial of Queen Victoria's diamond jubilee. The principal schools are the cathedral grammar school or King's School, founded in 1544, and the Sir Joseph Williamson's Mathematical School (1701), formerly for sons of freemen but now open to all. St. Bartholomew's Hospital (1708) occupies modern buildings, though the ancient chapel remains. A municipal airport has been provided by the corporation.

The Medway is navigable to Rochester Bridge and vessels drawing 26 ft. can reach it. Since the 1850s Rochester has become increasingly industrialized with cement, engineering, and other works. The towns of Rochester, Chatham, and Gillingham form one great conurbation sometimes known as the Medway Boroughs.

ROCHESTER, a city of Minnesota, U.S., in Olmsted County, home of the world-famous Mayo Clinic, is located about 80 mi. SE of Minneapolis-St. Paul in the rich diversified agricultural plains region of southeastern Minnesota. It has one of the largest poultry hatchery and breeding-farm operations in the country as well as a large dairy processing plant. The establishment of an electronic data-processing centre there has added to the growing industrial pattern of the city. The site at the confluence of three tributaries of the Zumbro River was chosen by settlers in 1854 and named for Rochester, N.Y. The city was incorporated in 1858 with a population of about 1,500.

Long famed as a health centre, Rochester houses the Mayo Foundation for Medical Education and Research, which is one of the world's largest graduate medical schools, and a branch of the University of Minnesota. There is a large privately operated hospital, and the Mayo Clinic which is actually a combination of hospitals and hotels. The clinic operates with the cooperation of the largest voluntary association of physicians, surgeons, medical technicians, and researchers in the world engaged in private practice. It was established in 1889 by William Worrall Mayo and his sons Charles Horace and William James Mayo and greatly stimulated Rochester's growth (*see* MAYO family).

These medical services attract patients from all over the U.S. and the world, causing a fairly constant transient population of 6,000–9,000 at any given time. (For comparative population figures *see* table in MINNESOTA: *Population.*) Along with excellent public education facilities, the town has five parochial schools, two schools of nursing, a school of music, and an evening community college. (J. T. LU.)

ROCHESTER, a city of northwestern New York, U.S., and seat of Monroe county, is located 70 mi. E of Buffalo and 90 mi. W of Syracuse, and is bisected by the Genesee river, which flows into Lake Ontario. The area is a prosperous manufacturing centre of quality photographic, optical and precision instruments; it is in the heart of a fruit and truck farming belt, and is gateway to the Finger Lakes resort area to the south.

History and Industrial Growth.—Rochester's first settlement dates from 1789. In 1788 Oliver Phelps obtained from the Seneca Indians land on the west side of the Genesee river to establish grist mills which would utilize the natural waterpower of the river falls. In 1789 Ebenezer ("Indian") Allen was deeded 100 ac. of this land for the construction of a sawmill and grist mill. Allen's venture was a failure, and further settlement was impeded by the malarial conditions known as Genesee fever.

Col. Nathaniel Rochester, Revolutionary War soldier and Maryland aristocrat, laid out the town in 1811 and named it Rochesterville, shortened in 1822 to Rochester. In 1812 the first dwelling unit, a log cabin, was occupied by Hamlet Scrantom and his family and marked the beginning of permanent settlement. Rochester was incorporated as a village in 1817 and chartered as a city in 1834.

The early economy was built upon the extensive wheat production of the Genesee valley region. Rochester's cheap natural waterpower and the city's connection with the eastern section of the Erie canal in 1822 assured its economic development as a milling centre. By 1840 the city, one of the early boom towns of the "west," had 20,000 residents. By the 1860s the clothing and shoe industries, given impetus by the American Civil War and the arrival of skilled immigrants, thrived; Rochester had also become the flour milling capital of America. But by 1878 this latter industry had passed its peak and was moving westward to Minnesota. After the Civil War, Rochester was transformed from the "flour city" to the "flower city." Large nursery and seed enterprises were developed with James Vick pioneering the mail order approach to selling seeds and shrubs. Although the business aspects of horticulture declined by the beginning of the 20th century, the influence of this industry is still manifested in the city.

By the latter part of the 19th century the area was developing into a quality manufacturing centre with emphasis upon photographic, optical and precision instrument products. Notable among these was George Eastman (*q.v.*), who became a major film and camera manufacturer.

Two industrialists, John Jacob Bausch and Henry Lomb, who perfected better techniques for grinding lenses, established their optical company there. Other entrepreneurs built successful manufacturing firms specializing in thermometers, machine tools, check protectors, mail chutes, glass-lined enameled steel tanks and dental equipment.

Frederick Douglass, the Negro abolitionist and runaway slave, published his antislavery paper, *The North Star,* in Rochester when the community was an important terminus for the Underground Railroad (*q.v.*) to Canada. The area is regarded as a cradle of modern Spiritualism because of Margaret and Katharine Fox's numerous seances (the "Rochester Rappings") in the late 1840s which attracted world attention.

Population.—Rochester (pop. [1960] 318,611; [1964] 305,849) is the central city of a standard metropolitan statistical area comprising Monroe, Livingston, Orleans, and Wayne counties with a population of 732,588. Although the city's population decreased by 4.2% between 1950 and 1960, the population of the metropolitan area increased by 20.3%. (For comparative population figures *see* table in NEW YORK: *Population.*) In the metropolitan area Irondequoit, Greece and Brighton are the largest suburban towns. These towns, along with Gates, Chili, Pittsford, Perinton, Henrietta, Penfield and Webster, are mainly residential, although industrial parks have been created in the last three. The fringe metropolitan area towns of Hamlin, Clarkston, Sweeden, Ogden, Riga, Wheatland, Rush and Mendon are predominantly rural in character, although limited suburbanization has occurred.

The area's earliest settlers were of northern European ancestry who migrated chiefly from New England. Prior to the Civil War, significant numbers of Irish and Germans became residents. Before World War I, large numbers of Italian immigrants arrived, and they represent the largest foreign-born group in the area.

Administration.—In 1925 Rochester adopted the city-manager form of government. The governing body, the city council, is composed of five councilmen-at-large and four district councilmen elected for four-year terms. The council selects one of its members as mayor. In the other 19 metropolitan towns the chief official, the supervisor, is elected for a two-year term.

Education, Culture and Recreation.—George Eastman's philanthropy supported or helped to establish a number of cultural and public facilities including the Eastman theatre, the city's university, the Dental dispensary and Durand-Eastman park.

The two major educational institutions are the University of Rochester (founded 1850) which includes the well-known Eastman school of music and school of medicine and dentistry, and the Rochester Institute of Technology (1829). Undergraduate collegiate education is provided by Nazareth (1924; Roman Catholic) St. John Fisher (1951; Roman Catholic) and Roberts Wesleyan

(1866) colleges, and theological education by St. Bernard's seminary and college (1893; Roman Catholic) and Colgate-Rochester Divinity school (1819; Baptist). The Rochester Philharmonic orchestra provides musical concerts during the winter season. The area has an excellent system of parks and recreational facilities including Hamlin State park on Lake Ontario, Genesee Valley park, the yacht basin in Irondequoit bay, the ski jump at Powder Mill park, and Highland park, with its floral displays, in Rochester.

ROCHE-SUR-YON, LA, chief town of the *département* of Vendée, western France, is situated on the right bank of the Yon, 65 km. (40 mi.) S. of Nantes by road. Pop. (1962) 22,231. The site of a 10th-century castle, it was captured by the English during the Hundred Years' War, and during the Wars of Religion in the 17th century it changed hands several times. Practically destroyed in 1794, the town was rebuilt by Napoleon in 1804 as the chief town of Vendée. It was called Napoléon-Vendée or Bourbon-Vendée, according to the ruling dynasty of the time, until the old name was restored in 1871. Little remains of the old town, but a fine Renaissance house still stands at the Place de la Vieille-Horloge. Other notable buildings include the Napoleon museum and the church of St. Louis, which contains the "Stations of the Cross" by P. J. A. Baudry, a native of the town. La Roche-sur-Yon is a prefect seat and a court of assizes, and has a tribunal of first instance. It is a railway centre, a market for horses and cattle and has an important *haras* (depot for stallions), flour mills and factories for clothing, electrical goods and plastics.

ROCKEFELLER, the name of a U.S. family founded by JOHN DAVISON ROCKEFELLER (1839–1937), industrialist, founder of the Standard Oil enterprise and of the first great American oil fortune. He was born in Richford, N.Y., on July 8, 1839, the son of a small trader. In 1853 the family settled in Cleveland, O. In 1859 Rockefeller formed a partnership with M. B. Clark in the produce and commission business. The first U.S. oil well was drilled that summer in Titusville, Pa., and in 1863 Rockefeller organized the firm of Andrews, Clark and company to enter the oil refining business as a sideline. Two years later the firm was reorganized as Rockefeller and Andrews. His brother WILLIAM ROCKEFELLER (1841–1922) joined him in the organization of William Rockefeller and company for the operation of a second refinery in Cleveland. In 1867 the two Cleveland refineries were consolidated into the partnership of Rockefeller, Andrews, Flagler and company, and three years later this firm was replaced by a joint stock company, the Standard Oil Company of Ohio, with John D. Rockefeller as president. Under his direction, this company obtained control of the oil industry by means of mergers, favourable railroad rates, rebates and other devices which at that time were not illegal. In 1882 was organized the Standard Oil trust, which controlled 95% of the oil refining business in the country and had in addition substantial interests in iron ore mines, lumber tracts, manufacturing plants, transportation and other businesses. In 1899 the supreme court of Ohio held this trust to be a violation of the Sherman Anti-Trust act, and the trust was replaced by the holding company device, Standard Oil of New Jersey, which existed until 1911 when the United States supreme court declared it also to be illegal. By this time John D. Rockefeller had retired from active business and was devoting his time to giving away a large part of his fortune. For this purpose he established charitable corporations governed by trustees and operated by officers devoted to a continuous study of opportunities for public service. It is estimated that by this means Rockefeller's benevolences mounted to more than $530,000,000. His first large benefaction was to The University of Chicago (*q.v.*), which received from him a total of $35,000,000. He died at his home in Ormond Beach, Fla., on May 23, 1937.

JOHN DAVISON ROCKEFELLER, JR. (1874–1960), the only son of John D. Rockefeller and Laura Spelman Rockefeller, was born in Cleveland, O., on Jan. 29, 1874. After graduation from Brown university in 1897, he entered his father's office, working closely with him in the business, philanthropic and civic enterprises of the family. His life was devoted primarily to philanthropic and civic activities. He was associated with his father in the creation and development of the Rockefeller Institute for Medical Research, the General Education board, the Rockefeller foundation and the Laura Spelman Rockefeller memorial. In 1923 he founded the International Education board, which operated in the fields of the natural sciences, the humanities and agriculture until it was terminated in 1937. Deeply interested in the conservation of natural resources and in preserving historic places, the younger John D. Rockefeller made many contributions for these purposes, including among them the restoration of Williamsburg, Va. His contributions from Jan. 1, 1917, to Dec. 31, 1955, amounted to about $400,000,000. He died in Tucson, Ariz., on May 11, 1960.

NELSON ALDRICH ROCKEFELLER (1908–), second son of John D. Rockefeller, Jr., was born at Bar Harbor, Me., on July 8, 1908. Graduated from Dartmouth College in 1930, he helped manage several family enterprises, notably Rockefeller Center in New York City. During World War II he served under Pres. Franklin D. Roosevelt as coordinator of inter-American affairs (1940–44) and as assistant secretary of state (1944–45). He was undersecretary of the Department of Health, Education, and Welfare, 1953–54, special assistant to the president, 1954–55, and chairman of the president's advisory committee on government organization, 1953–58. A collector of modern art, he became a trustee of the Museum of Modern Art in 1932, and was a founder of the Museum of Primitive Art. Entering politics as a liberal Republican, he was elected governor of New York in 1958 and re-elected in 1962. He was prominently mentioned as a candidate for the Republican presidential nomination in 1960 and, as an active candidate, in 1964 he led the unsuccessful opposition to Barry Goldwater's nomination. In 1966 he was reelected for a third term as governor of New York.

He married Mary Todhunter Clark in 1930. Their children were Rodman, Ann and Steven (twins), Michael (d. 1961), and Mary. They were divorced in 1962, and he married Margaretta Fitler Murphy in 1963. Their children are Nelson Aldrich and Mark Fitler.

WINTHROP ROCKEFELLER (1912–), fourth son of John D., Jr., was born in New York City on May 1, 1912. He attended Yale University, 1931–34, and worked in the Texas oil fields, 1934–37. In New York he helped organize the Greater New York Fund and became a leader and board member of the National Urban League, serving as a trustee, 1940–64. In 1953 he settled in Arkansas and developed the 34,000-ac. Winrock Farms, noted for its prize herd of Santa Gertrudis breeding stock, and Winrock Enterprises (manufacturing, building, land development), and the philanthropic Rockwin Fund. In 1955 he was named head of the Arkansas Industrial Development Commission. Active in building the state's Republican Party, he became Republican National Committeeman in 1961, and in 1964 campaigned unsuccessfully for the governorship. In 1966 he was elected Arkansas's first Republican governor since 1874.

A director of Rockefeller Brothers and of Rockefeller Center in New York, he became chairman of the board of Colonial Williamsburg Inc. His marriage to Barbara ("Bobo") Sears in 1948 ended in divorce in 1954; they had one son, Winthrop Paul. Rockefeller's second marriage was to Jeanette Edris, in 1956.

Others of the five sons of John D. Rockefeller, Jr., have been associated with the various Rockefeller benevolent corporations, banks, and other businesses: JOHN DAVISON ROCKEFELLER III (1906–), chairman of the Rockefeller Foundation and of the General Education Board; LAURANCE S. ROCKEFELLER (1910–), chairman of Rockefeller Brothers and a conservationist; and DAVID ROCKEFELLER (1915–); president of the Chase Manhattan Bank and chairman of the Chase International Investment Corporation, chairman of the board of Rockefeller Institute, of the board of trustees of the Museum of Modern Art, and trustee of the Council on Foreign Relations; author of *Unused Resources and Economic Waste* (1940).

JOHN DAVISON ROCKEFELLER IV (1938–), son of John D. III, worked in the Action for Appalachian Youth poverty program

in West Virginia, in the mid-1960s; he was elected as a Democrat to the West Virginia House of Delegates in 1966. In 1967 he married Sharon Lee Percy, daughter of U.S. Sen. Charles H. Percy (Republican, Ill.).

ROCKETS AND GUIDED MISSILES. Rockets and guided missiles are treated in a single article because almost all such devices rely on similar methods of propulsion and control. Recognition of rocket power as the key to space exploration is nearly a century old, but the state of technology did not permit the use of this propulsive technique until after World War II. Guided-missile weapon systems had their origin in unmanned, radio-controlled aircraft before World War I. Although pulse-jet, turbojet and ramjet engines have been used on many missiles, rocket power is most widely used for propulsion.

I. INTRODUCTION: ROCKETS

Rocket is the generic term for a wide variety of jet-propelled missiles, research vehicles, thrust devices and fireworks. Forward motion results from reaction to a rearward high-speed flow of hot gases generated in the rocket motor. Either solid or liquid propellants providing combustion gases, or stored high-pressure cold gas may be used.

A rocket motor, or engine, is one of the family of jet-propulsion devices whose other members include turbojet, pulse-jet and ramjet engines. The rocket engine is unique, however, in that the elements of the propulsive jet (fuel and oxidizer) are self-contained within the vehicle. The thrust produced is independent of the atmosphere or medium through which the vehicle travels. Other kinds of jet-propulsion engines carry their fuel only. This fuel is burned with the oxygen content of the air scooped into the engine as the vehicle flies along. Thus these other varieties of jet engines are called air-breathing and are limited to operation within the blanket of atmosphere which surrounds the earth. The upper limit of travel for air-breathing jet engines is about 90,000 ft.

Rocket power is used for both military and peaceful purposes—and has been for hundreds of years. Rockets can be used to hurl explosives against targets thousands of miles away, or to lift data-gathering instruments—and man—into interplanetary space for scientific research and exploration.

The recorded history of rockets dates from the 13th century, but interest in them has risen and fallen as various other devices, such as the mortar and artillery, became competitive. Since World War II, however, rocket technology has reached such a level that it is doubtful that rockets will ever disappear again from the scene. As matters stand now, there is no technical competitor for rocket-propulsion systems for many missions. For instance, a rocket-powered ballistic missile can be fired against targets 6,000 mi. or more away. The speed at which it travels may be as high as 15,000 m.p.h. At the same time, as the recognized power plant for space flight, the rocket is the key to exploration of nature in a new dimension. In fact, the same basic vehicle used to carry an explosive warhead over intercontinental distances can be used instead to place man or thousands of pounds of scientific instruments in satellite orbit around the Earth. Launchings of Earth satellites and of lunar and interplanetary research probes are but the prelude to an era of space exploration. Until 1955 man was a passive observer of laws of celestial mechanics. Since then he has begun to use these laws by the application of rocket power.

II. ROCKET HISTORY TO WORLD WAR II

1. Early History.—No one knows when or by whom rockets were invented. In all probability the rocket was not suddenly "invented" but evolved gradually over a long period of time, perhaps in different parts of the world at the same time. Some historians of rocketry, notably Willy Ley, trace the development of rockets to 13th-century China, a land noted in ancient times for its fireworks display. In the year A.D. 1232, when the Mongols laid siege to the city of Kai-feng Fu (K'ai-feng), capital of Honan province, the Chinese defenders used weapons that were described as "arrows of flying fire." There is no explicit statement that these arrows were rockets, but some students have concluded that they were because the record does not mention bows or other means of shooting the arrows. In the same battle, we read, the defenders dropped from the walls of the city a kind of bomb described as "heaven-shaking thunder." From these meagre references some students have concluded that the Chinese by the year 1232 had discovered gunpowder and had learned to use it to make explosive bombs as well as propulsive charges for rockets.

In the same century rockets appeared in Europe. There is indication that the first use was by the Tatars against the Polish duke Henry in the battle of Legnica in 1241. The Arabs used rockets on the Iberian peninsula in 1249; and in 1288 Valencia was attacked with rockets. The Italian historian L. A. Muratori writes that a lucky hit of a rocket was decisive in a battle for Chioggia in 1379.

About 1248 Roger Bacon (*q.v.*), an English Franciscan monk, wrote formulas for gunpowder in his *Epistola,* with great secrecy and the use of ciphers. He evidently experimented with various proportions of the three classic ingredients, saltpetre (nitre), charcoal and sulfur, raising the amount of saltpetre to 41%. The Chinese had used rather less saltpetre, which resulted in slower-burning mixtures. In Germany, a counterpart of Bacon, Albertus Magnus, was writing of powder charge formulas for rockets in his book *De mirabilis mundi.* About 1325 the first firearms were invented, utilizing a closed tube and gunpowder to propel a ball charge somewhat erratically over varying distances. Military engineers then began to invent and refine designs for guns and rockets, on a parallel basis. (*See* ARTILLERY.)

The French historian Jean Froissart (*q.v.*) suggested that rockets fired from tubes would give them better direction. In his book *Bellifortes* (1405), Konrad Kyeser von Eichstadt wrote of several designs of rockets. In Italy Joanes de Fontana conceived a number of novel war weapons based on rocket propulsion. One was a rocket-driven car designed to breach walls or gates. Another was a naval torpedo, designed to skim across water and ram its spiked nose into ships. Many other ideas were suggested in print, such as Count Reinhart von Solm's rockets with parachutes; or the count of Nassau's underwater explosive rocket. The extent to which many of these designs were reduced to working models or

weapons is not known. By now rockets were used also for signaling and, especially by pirates, for setting fire to the tarred rigging of ships at sea. They had many names, such as "flying fire" or "wild fire."

The tale of Wan-Hu, presumably legendary, is an interesting milestone in the early history of the rocket. As the story goes, about the year 1500 a Chinese, Wan-Hu, made what must have been the first attempt at rocket flight, constructing a vehicle utilizing two large kites to which were attached some sort of seat. Forty-seven rockets were attached and fired simultaneously. Wan-Hu and his contrivance simply disappeared in the loud explosion which followed!

Of considerable historical interest are the work and writings of a Polish artillery expert, Kazimierz Siemienowicz. His monograph on military weapons, *Artis magnae artilleriae, pars prima,* is noteworthy for three reasons. It contains remarkably fine drawings of the step (or staged) rocket, the clustered rocket and the winged rocket. All of these concepts were to prove important several hundred years later. Siemienowicz' book was published (in Latin) in Amsterdam in 1650. Translation of this document into French (1651), German (1676), English and Dutch (1729) gives eloquent testimony to the importance of this work. More than 200 figures were drawn on copperplate by Siemienowicz himself. (*See* fig. 1.) Design characteristics of rockets, such as length-to-diameter ratios, are given, as well as such constructional details as how to shape properly dimensioned holes for rocket nozzles. The earliest known description of the step rocket was by Johann Schmidlap, a fireworks maker, in 1591.

By 1668 military rockets, hard-pressed by development of guns and cannons, had increased in size and performance. In that year, a German, Col. Christoph Friedrich von Geissler, designed a rocket weighing 132 lb., constructed of wood, wrapped in glue-soaked sailcloth. It carried a gunpowder explosive charge weighing 16 lb.

Although the art of constructing rockets had now become quite widely known there was little appreciation or understanding of exactly how and why a rocket operated; *i.e.*, the physical principles involved. It was not until the last quarter of the 17th century that Isaac Newton formulated his famous laws of motion laying the basis for modern mechanics. Prior to this time Aristotelian theories of motion—philosophical in nature and unsupported by physical fact—had persisted for 20 centuries. Newton stated in his third law that every action is accompanied by an equal reaction in the opposite direction. The thrust of a rocket is derived from the reaction, in the opposite direction, to the expelled jet of combustion gases.

FIG. 1.—HISTORICAL EXAMPLES OF ROCKETS

(A) conventional stick-guided war rocket or fireworks skyrocket, and some early design concepts of (B) a step rocket, (C) a clustered rocket and (D) a fin-stabilized glide rocket. Drawings by Kazimierz Siemienowicz from *Artis magnae artilleriae, pars prima* (1650)

Despite the hard work of individual European enthusiasts, the use of rockets in military campaigns was sporadic. A revival of interest occurred after a series of battles in India late in the 18th century. Haidar Ali, prince of Mysore, developed rockets as weapons. The rockets had metal tubes, permitting higher internal pressures. They weighed 6–12 lb. and were flight-stabilized by a 10-ft. bamboo stick. The range of these rockets was a startling 1–1½ mi. Although not individually accurate, dispersion errors of individual rockets became unimportant when large numbers were fired in mass attacks. These rockets were particularly effective against cavalry. Haidar Ali's son, Tipu Sahib, continued to develop and expand the use of rocket weapons, increasing the number of rocket gunners from 1,200 to a corps of 5,000. The British suffered heavily, particularly in battles at Seringapatam in 1792 and 1799.

2. 19th-Century Developments.—The news of the successful use of rockets in these engagements spread through Europe. A British colonel, William Congreve, began to experiment privately. Within a few years he was able to match and exceed the range of the Indian rockets. In 1806 British rockets caused great fires during an attack on Boulogne. The next year a massed attack, using about 25,000 rockets, burned most of Copenhagen to the ground. In the decisive battle of Leipzig (1813) Congreve rockets are credited with playing an important role. Later in the same year Danzig was subjected to a series of massed rocket bombardments in three successive months. The last attack caused the surrender of the city.

In the United States, the British used their rocket corps in two important engagements during the War of 1812. One was the battle of Bladensburg (Aug. 24, 1814) when their use drove back the American troops. As a result, the British were able to advance on Washington, D.C., capturing and burning the city. In September the British forces attempted to capture Ft. McHenry, which guarded Baltimore harbour. They were unsuccessful but on that occasion Francis Scott Key, inspired by the sight of the night engagement, wrote the stirring words of the *Star Spangled Banner,* later adopted as the U.S. national anthem. "The rockets' red glare" and "bombs bursting in air" ever since have continued to memorialize Congreve's rockets.

Back in Europe, the Dutch army bought some Congreve rockets. A Captain de Boer conducted some experiments and arrived at a proposal to eliminate the heavy, stabilizing guide stick and substitute three metal vanes. Despite the fact that this lighter design should have worked, it was apparently not adopted. The stick-stabilized rocket was used until William Hale's invention several decades later.

Congreve's rockets were successful for several reasons. He experimented with a number of black powder formulas and set down standard specifications. In the production of hundreds of thousands of rockets over two decades apparently a number of small refinements in design were made. Although none of these modifications materially improved performance, the sum total of the improvements resulted in a fairly reliable and potent weapon in the hands of a skilled rocket brigade. Congreve rockets ranged in weight from 25 to 60 lb. Some warheads were incendiary, some steel ball charges for antipersonnel use. Ranges increased to nearly three miles. They were competitive in weight and performance with the ponderous ten-inch mortar and were much more mobile. In appearance they resembled large skyrockets, the guide stick being 12–16 ft. long. Being recoilless, their launching equipment was simple and lightweight, and they could be fired from small boats. Thin copper tubes were used for initial directional guidance or, for massed bombardment, collapsible A-frames were employed. The success of Congreve's rockets caused the addition of rocket batteries to artillery units or the formation of independent rocket corps in most armies of Europe, as far east as Russia.

The next significant development in rocketry occurred about the middle of the 19th century. William Hale, a British subject, contrived a way of eliminating the dead weight of the stabilizing

stick. When he placed a series of canted and curved vanes at the rear of the rocket, the exhaust gases imparted a spin to the rocket. Spin-stabilized rockets were a real improvement in performance and ease of handling. But by this time black powder rockets could no longer compete with artillery. The rocket corps of most European armies had been dissolved. Firearms and heavy field-pieces with rifled bores were outclassing rockets except on rare occasions. These exceptions were usually in mountainous terrain. On such ground, rockets could move into choice firing locations while the much heavier mortars were confined to roads or flat ground. Thus we find that the Austrian rocket corps, using Hale rockets, won a long series of engagements in such terrain against Hungary and Italy. Other successful uses were by the Dutch colonial services against natives in the Celebes and by Russia in a series of engagements in the Turkestan War.

Two thousand Hale rockets were produced by the U.S. army for the Mexican War, but from the little that has been recorded they were not particularly successful. Although the *U.S. Ordnance Manual* of 1862 listed 16-lb. Hale-type rockets with a maximum range of about 1.25 mi. their use in the American Civil War is not known. There is a story that President Lincoln was interested in rocket development and was narrowly missed by an explosion in a test at the naval gun factory in Washington.

The extensive use of Congreve and Hale rockets lasted less than a century though they had appeared widely and were well known. Various applications of rocket power for other than military purposes began to appear. One of the best known was the use of a rocket to carry a lifeline to sailing ships in distress or stranded near shore. A thin line was first carried to the ship by the rocket. Then the crew would haul a heavier line out and use a breeches buoy to transfer the men, one at a time, to safety. In the 19th century hundreds of lives were saved in this way, using line-throwing mortars and rockets. Another application of rockets was in aiding lifeboats to negotiate a heavy surf. Rockets were used to throw a small grappling anchor with a light line over the surf onto the beach. By this technique, the boat could be kept straight as the occupants pulled themselves toward shore through the surf.

A line-carrying rocket designed by Colonel Boxer about 1855 achieved increased range by firing two rocket motors, one after the other, tandem fashion. This was the first known application of a concept sketched by Siemienowicz 200 years earlier. It was less efficient than a modern two-stage rocket since the container of the first motor did not drop off but was carried along empty.

Signal flares also were carried aloft by rockets. One design of such a rocket by Congreve utilized a parachute to keep the flare visible for a longer period of time. Capt. William Scoresby hunted whales by rocket-propelled harpoon in 1821. A woodcut from an 1865 newspaper, advertising the sale of such devices, shows a seaman launching a rocket harpoon from a shoulder-held tube equipped with a circular blast shield. The launcher appears quite similar to the bazooka of World War II.

One interesting 19th-century development was the concept of a rocket-propelled torpedo. Both the U.S. army and the British navy conducted experiments with such devices in the period 1860–80 and several ingenious devices were designed. Nevertheless, none of this work led to a real weapon. One of the fundamental problems of the rocket torpedo, as pointed out by William Hale, was that as the powder in the rocket motor was consumed, the torpedo grew lighter, making it difficult to hold the torpedo at constant level below the surface.

On the sidelines during the development of military rockets there were individual enthusiasts and inventors in nearly every country. Largely unknown, and sometimes considered a dangerous nuisance, they achieved varied success and recognition. In the early 19th century Claude Ruggieri, an Italian rocket maker, staged a number of shots in Paris in which rats and mice were sent aloft by rockets and returned by parachute. Ruggieri even planned to send up a small boy, using a rocket cluster, but the police intervened.

During the 1880s and 1890s, inventors in all countries began to consider reaction propulsion. There were designs of flying devices propelled by steam jets (Charles Golightly), rocket-propelled airplanes (Werner von Siemens) and airships (Gen. Russell Thayer, Nicholas Petersen, Sumter B. Battey). There was even a helicopter design (Horatio F. Phillips) utilizing reaction-propelled, counterrotating blades.

In the light of the times, many of these concepts were ingenious and prophetic in nature. It should be remembered that at that time the only existing mechanical prime movers were the steam engine and clockwork. Steam boilers were too heavy and clockwork mechanisms too limited in power to be of value in airborne devices. It was logical, therefore, to turn to reaction jets of steam or rocket gases. Models of some of these inventions, such as Phillips' helicopter, actually flew. But technology had not advanced sufficiently for any of these aerial, reaction-powered devices to be practical, despite the fact that, in theory, the principles involved in many cases were sound. What was lacking was sufficient power. But sufficient power was coming. In 1845 the German chemist Christian Friedrich Schönbein accidentally discovered guncotton (nitrocellulose). Fifteen years later Alfred Nobel was commercially producing nitroglycerin. Use was made of these and other combustible materials in firearms and artillery but it was about 50 years or so before their value was to be demonstrated for rockets. (*See* PROPELLANTS.)

The schemers and dreamers continued, however. In 1881 a Russian explosives maker, Nikolai Ivanovich Kibalchich, was arrested for his part in an assassination attempt on Tsar Alexander II. While in prison he conceived of a rocket airplane which functioned by successive explosions of compressed powder candles. Kibalchich's writings were doomed to lie in prison archives after his execution until the overthrow of the government in 1917.

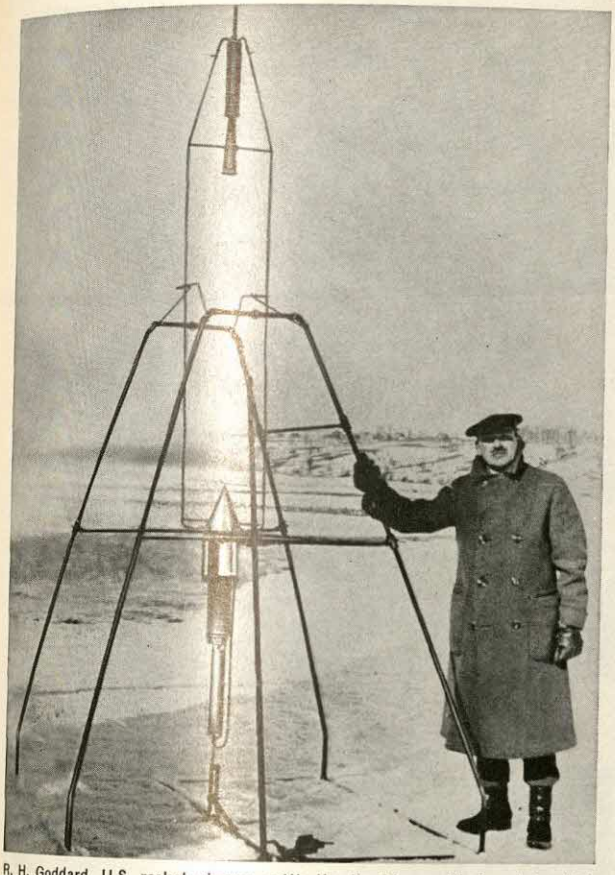
About 1891 an ingenious German inventor, Herman Ganswindt, conceived of a propulsion system, rather similar to that of Kibalchich but employing steel cartridges loaded with dynamite. But Ganswindt went further. He wanted to give his vehicle sufficient speed to attain escape velocity; *i.e.*, to leave the Earth. Apparently, Ganswindt was the first to connect the potentiality of rocket propulsion to space flight. In other countries the same dream was about to occur.

In Russia in 1895 a young mathematics teacher in Borovsk (district of Kaluga) published his first article on space travel. Konstantin Eduardovich Tsiolkovski was among the first to grasp the importance of exhaust velocity and the reason rockets had been limited by black powder formulas. He recognized that by using liquid propellants, *e.g.*, liquefied hydrogen and oxygen, much greater efficiencies would result. Tsiolkovski continued to make important contributions to the theory of space vehicle design but the language barrier, combined with his modesty and retiring nature, caused him to be little known for many years.

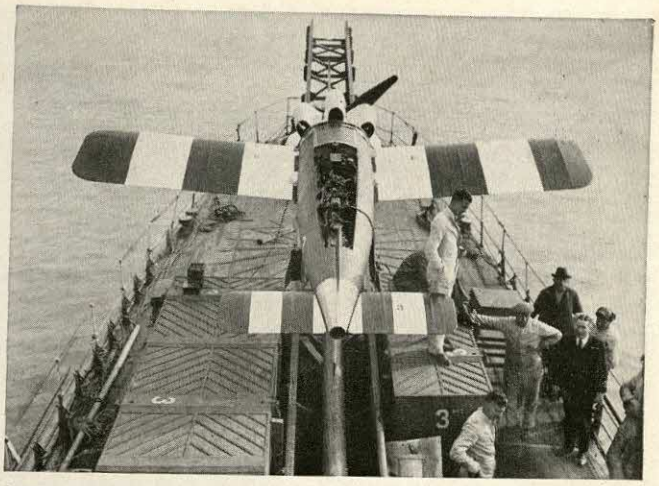
3. 20th Century to World War II.—In Sweden about the turn of the century, inventor Baron von Unge interested Nobel in a device described as an "aerial torpedo." Based upon the stickless Hale rocket, it incorporated a number of design improvements. Velocity and range were increased and about 1909 the Krupp armament firm purchased the Von Unge patents and a number of rockets for further experimentation. But these rockets still used black powder as the propelling charge and their capabilities were limited. Von Unge, however, believed that his aerial torpedoes would be valuable as air-to-air weapons between slow-moving dirigibles.

In the U.S., meanwhile, Robert H. Goddard (*q.v.*) was conducting theoretical and experimental research on rocket motors at Worcester, Mass. Utilizing high-pressure steel motors with a tapered nozzle, he achieved much greater thrust and efficiency. Another of Goddard's concepts was a long-range bombardment rocket whose motor was fired in pulses. Somewhat similar to the pulsed momentum principle suggested by Kibalchich and Ganswindt, the impulses were to have derived from charges of solid fuel injected into the combustion chamber in rapid succession.

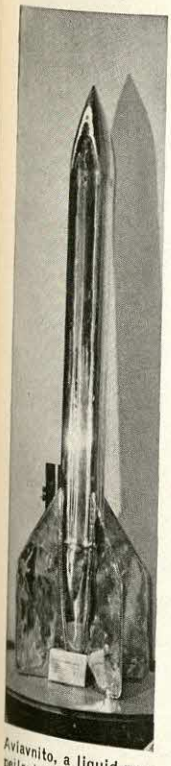
During World War I Goddard developed a number of designs of military rockets weighing 1.5 to 17 lb. to be launched from a lightweight hand launcher. By switching from black powder to double-base powder (40% nitroglycerin, 60% nitrocellulose), a



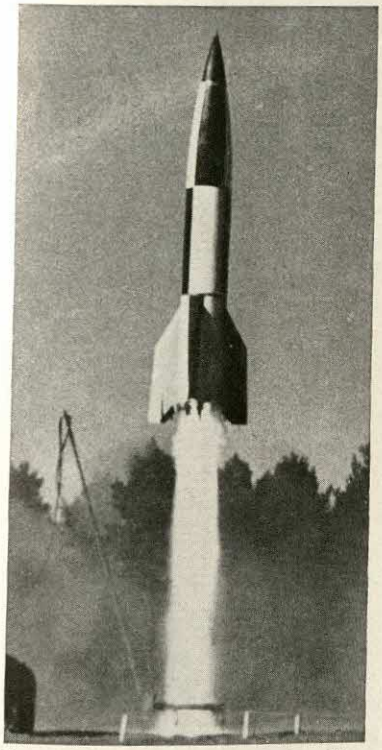
R. H. Goddard, U.S. rocket pioneer, with the liquid-propellant rocket which he designed and launched in 1926. The fuel was liquid oxygen and gasoline



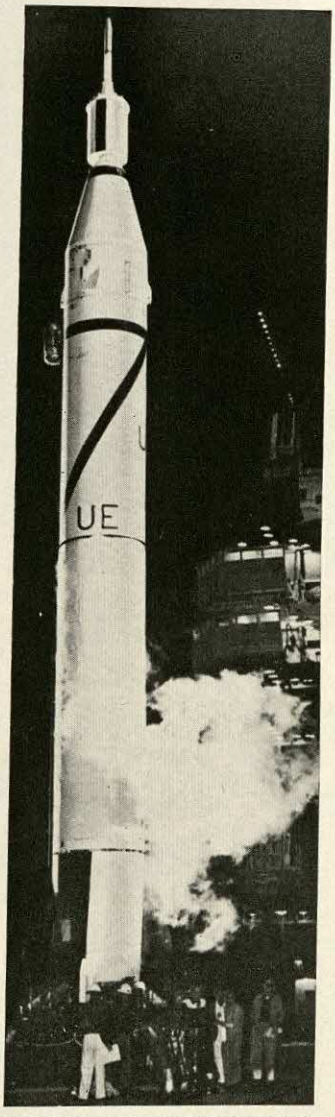
Larynx, early British guided weapon, being launched by catapult in 1927. Earlier similar radio-guided, drone aircraft were tested in U.S. and Great Britain during World War I



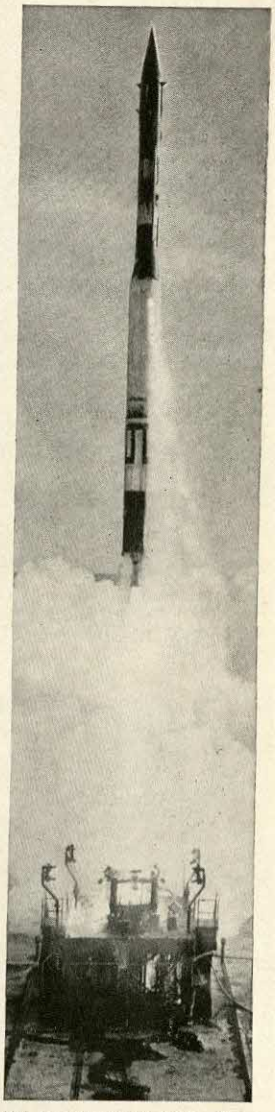
Aviavnito, a liquid-propellant rocket of the U.S.S.R. in 1936. The fuel was oxygen and ethyl alcohol



German V-2, a 46-ft., 14-ton missile with a 200-mi. range. First fired in 1944, it carried a conventional warhead weighing one ton



U.S. Jupiter C, which placed first U.S. satellite (Explorer I) weighing 18.13 lb., in orbit on Jan. 31, 1958, from Cape Canaveral, Fla.



U.S. Vanguard rising from Cape Canaveral, Fla., March 17, 1958, placed a 3¼-lb. satellite into an earth orbit

ROCKETS AND GUIDED MISSILES

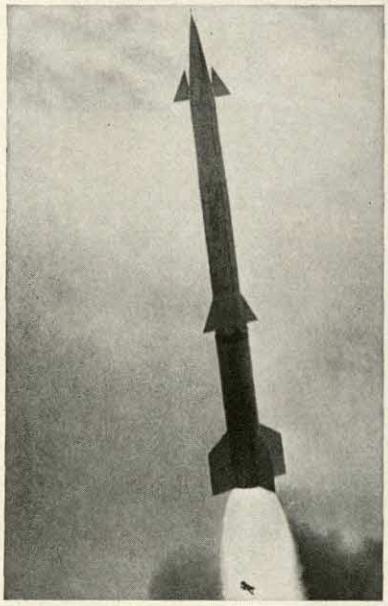
Hound Dog air-to-surface missile flying at a low level following its launch from a B-52

Redeye, U.S. army surface-to-air missile, weighs 28 lb., is fired from a bazooka-type launcher



Test model of Nike-Zeus, an antimissile missile of the U.S. army, being fired at White Sands, N.M.

Tartar, surface-to-air missile of the U.S. navy, designed for antiaircraft use. Radar beam-guided, a homing system takes control as the vehicle approaches the target

Hawk, surface-to-air missile of the U.S. army, designed to intercept low-flying aircraft at a maximum range of 22 mi.

ASROC, antisubmarine missile of the U.S. navy, poised for loading into a launcher. The front half is a homing torpedo

Honest John, surface-to-surface free-flight rocket of the U.S. army. Axially mounted spinner rockets stabilize the flight path. Range is about 12 mi.

GUIDED MISSILES OF THE UNITED STATES

far more potent propulsion charge was obtained. These rockets, forerunners of the bazooka of World War II, were proving successful under tests at the U.S. army Aberdeen (Md.) proving ground when the armistice was signed. But Goddard's main interest as a physicist was in utilizing the new potential of rockets to reach high altitudes. His notebooks, after his death, revealed interest in a circumlunar rocket (carrying a camera to photograph the far side of the moon), in ion and nuclear rocket propulsion and in interplanetary exploration.

Using Smithsonian institution funds, Goddard continued his research at Worcester. Switching from solid to liquid propellants he launched the first liquid-propellant rocket March 16, 1926, from a farm in nearby Auburn, Mass. Liquid oxygen and gasoline propellants were used. The altitude attained was only 184 ft., but the significance was as great as the few feet the Wright brothers flew on their initial flights at Kitty Hawk.

Later, under Daniel and Florence Guggenheim foundation funds, Goddard developed further research rockets at Roswell, N.M., in the 1930s. Although he never achieved the altitudes or velocities he knew were possible, Goddard proved himself a brilliant inventor. His later designs utilized both turbopumps and gyrostabilizers. Vanes were used to deflect the rocket exhaust to correct deviations from the planned flight path.

In 1919 the Smithsonian published a historic paper by Goddard entitled, *A Method of Reaching Extreme Altitudes*. At the end of the paper he extrapolated his calculations and discussed the possibility of a rocket reaching the moon with a payload of flash powder to signal its arrival to astronomers. The significance of this work, like Tsiolkovski's, was that the suggestions were made not by an exuberant inventor or enthusiast but by a thoughtful scientist with sound academic background.

World War I saw very little use of rocket weapons. Artillery development far outclassed existing rocket designs which had changed little in the previous decades. The French, however, did successfully use incendiary rockets against hydrogen-filled dirigibles.

Some French airplanes equipped with wing-launched rockets successfully attacked captive observation balloons. German units devised a technique for dealing with barbed wire entanglements in trench warfare: a heavy rocket was used to lob a grappling hook with a trailing line across the wire; the hook would be wound back by means of a winch, pulling down the wire.

In 1923, while Goddard was working in Worcester, an obscure German mathematics teacher, Hermann Oberth, published *Die Rakete zu den Planetenräumen* ("The Rocket Into Interplanetary Space"). In this thin pamphlet was set forth, with a grasp remarkable for his time, the potentialities of rockets to achieve great velocity. Oberth pointed out that science and technology had reached a level where the realization of manned space vehicles might be achieved in several decades. A later, major work, *Wege zur Raumschiffahrt* ("Way to Space Travel"; 1929), not only set forth design concepts for immense interplanetary space vehicles utilizing clustered liquid-propellant motors but also contained a chapter on electric propulsion and the ion rocket, predating actual development work on electrostatic propulsion by 30 years.

The decade which followed was an exciting one. Germans such as Walter Hohmann, Hermann Noordung and Austrian Baron Guido von Pirquet published technical studies on rocket power and space vehicles. In France, the famous aviator and test pilot Robert Esnault-Pelterie lectured and wrote on high-altitude rockets and interplanetary flight. It was Esnault-Pelterie who coined the term astronautics for the science of space flight. In 1929 Esnault-Pelterie and the French banker André Hirsch established an annual astronautics award for the experimenter who had done most to further space flight. In the U.S.S.R., Jakov I. Perelman and Nikolai A. Rynin were interpreting and expanding Tsiolkovski's work.

This was also the period of the promotional use of rockets—to propel cars and sleds as carried out by the German engineer, Max Valier. Although Valier was a competent designer of both solid and liquid rocket motors, such applications of rocket power tended to mislead the public by deflecting attention from those fields where rockets had no competition; *i.e.*, in high-altitude, high-speed flight.

In the period 1927–33 rocket and space flight societies were formed in Germany, Austria, the U.S.S.R., the U.S. and Great Britain. These groups provided a meeting place for discussion and experimentation and their journals became a means of disseminating information. Willy Ley, a founding member of the German space flight society, related the story of these formative years of modern rocket experimentation in his book *Rockets, Missiles and Space Travel* (rev. ed., 1957).

Further developments in rocket technology and its application to guided missiles during and after World War II are described in the section *Miscellaneous Applications of Rocket Power*, below.

III. ROCKET AND GUIDED-MISSILE SYSTEMS (WORLD WAR II AND LATER)

By World War II aircraft design, gyrostabilizing systems, rocket-engine technology, radio communications and radar had given man the tools with which to create effective short- and long-range guided missiles. Literally hundreds of designs and modifications of designs were developed by technologically capable countries. Those countries possessing nuclear bombs produced intercontinental ballistic weapons equipped with nuclear warheads, thus achieving a capability of awesome dimensions.

There is as yet no universally accepted system of classification of rockets and guided-missile systems. However, virtually all developments may be included within one of the following six categories of application: (1) surface-to-surface; (2) surface-to-air; (3) air-to-surface; (4) air-to-air; (5) space launch; (6) drones, decoys and test vehicles. Free-flight, or unguided, rockets are included in appropriate surface- or air-launch applications. Underwater missiles are included in the surface-launch category.

1. Surface-to-Surface.—*Free-Flight Rockets.*—All rocket weapons from the 13th to the 20th century were free-flight rockets. They differ from other rockets and guided missiles in that they cannot alter trajectory in flight. Stability in flight was achieved by a long stick, fins or canted exhaust nozzles.

By the 1930s the German army had embarked on a program to refine the design of rockets. Among the innovations were double-base powder and high-explosive warheads. One of the most widely used of the German surface-launched weapons was the *Nebelwerfer*, which hurled 15-cm.- and 21-cm.-calibre rockets from six-barreled launchers. These were heavily used against the Soviet Union during World War II. The rocket-powered 15-cm. (about 6-in.) shell was about 40 in. long and weighed about 80 lb. Maximum range was more than 6,000 yd. Later, a *Wurfgerät* rocket launcher was introduced which hurled 21-cm.-calibre rockets. The total firing weight of each projectile was about 200 lb., and the maximum range was 2,000 yd.

Other German developments included the *Panzerfaust* and *Panzerschreck*. These were hand-held, tube-launched rockets similar to the U.S. bazooka. One other rocket worthy of note was the *Rheinbote*, a four-stage, solid-propellant rocket. It weighed nearly two tons, was about 40 ft. long and had an impressive range—135 mi. However, the payload of 88 lb. of high explosive could not compete with other weapons such as aircraft bombardment and the V-2. The *Rheinbote* was significant, however, in that practical recognition was made of the value of the step principle suggested by Schmidlap more than 300 years before.

In Great Britain development of rockets was considered by the war office in 1934, and by the next year a program headed by A. D. Crow (later Sir Alwyn) was under way. Initial effort was aimed at antiaircraft weapons (see *Surface-to-Air*, below). As the war developed a 5-in. rocket, capable of projecting a 30-lb. bomb to ranges of 2–4 mi., was developed for heavy coastal bombardment prior to landings. Automatic ripple fire in successive groups reduced the chance of mutual interference between rockets. With this weapon a tremendous rate of firepower was possible. For example, a single rocket ship was able to launch 1,000 lb. per second of high explosive for nearly a full minute.

The United States did not commence active development of rockets until mid-1940. At that time, the National Defense Research committee (NDRC) authorized a program under the direction of C. N. Hickman at Indian Head, Md.; Hickman had worked with Goddard on the hand-launched rocket tests at Aberdeen in 1918. Aided by army Capt. L. A. Skinner, Hickman supervised the development of a refined design, known as the bazooka. About 20 in. long, 2.36 in. in diameter and weighing 3.5 lb., the rocket was fired from a 4.5-ft. shoulder launcher which weighed 14.5 lb. The bazooka was used extensively against tanks. Its maximum range was short (600 yd.) and it traveled slowly but it carried a particularly potent warhead weighing 1.8 lb. (*See* BAZOOKA.)

Another U.S. army development was the Calliope, a 60-tube launching projector for 4.5-in. rockets mounted on Sherman-type tanks. The launcher was mounted on the tank's gun turret, and both azimuth and elevation were controllable. Ripple fire was used to eliminate interference of rockets in salvo firing. Other launchers were developed for trucks and jeeps.

Close liaison was established between the U.S. NDRC and similar research groups in Great Britain. Advantage was taken of earlier rocket developments of the British. In this cooperative effort the U.S. developed an antisubmarine rocket-propelled weapon, known as Mousetrap, based upon a similar British design, Hedgehog.

Other conventional rockets developed in the U.S. included a 4.5-in. in barrage rocket with a range of 1,100 yd. and a 5-in. rocket of longer range. This latter rocket was extensively used in the Pacific theatre from type LSM-R launching barges against shore installations particularly just before landing operations. Firing rates of these flat-bottom boats was 500 per minute. Other U.S. rockets were used for smoke laying (3.5 in. and 4.5 in.) and demolition (7.2 in.).

Because the U.S. had great industrial capacity, unhampered by air raids, and urgent needs for its own forces as well as for allies, its production of solid-propellant rockets increased to a high rate by the end of the war. At the close, rockets of all sizes were being manufactured at the rate of 1,000,000,000 per year. Weights of different designs ranged from 3 to 1,300 lb.; diameters, 2 to 12 in.; lengths, 1 to 10 ft.; velocities, 650 to 1,500 ft. per second; maximum ranges (ground firing), 40 to 10,000 yd.; and accuracies (angular dispersion), $\frac{1}{16}°$ to 3°.

As far as is known, Russian rocket development activity during World War II was limited. Extensive use was made of barrage, ripple-fired rockets against the Germans. Both A-frame and truck-mounted launchers were used. According to Ley (see *Bibliography*) much of the rocket material came from the U.S. Later, however, the Russians mass-produced a 3.2 in. rocket known as *Katyusha*. From 16 to 60 *Katyushas* were fired from a boxlike launcher known as the Stalin Organ, mounted on a gun carriage.

After World War II, the impetus of advanced rocket designs of free-flight rockets continued in the U.S. but at a much slower pace. By 1950 the U.S. army had begun development of the Honest John rocket, and it became operational in 1955. As development continued on this rocket, it became a very flexible and highly mobile weapon. It could be fired from a truck-mounted, straight-rail launcher or from a helicopter-portable launcher.

The Honest John is 27 ft. long, about 30 in. in diameter and weighs 4,830 lb. It has a range of more than 15 mi. and can be equipped with either a high-explosive or nuclear warhead. The rocket is both spin-stabilized and fin-stabilized. After it leaves the launcher, small rocket motors located forward of the head of the sustainer engine (but arranged tangentially to it) fire and impart a slow spin to the rocket. The four large stabilizing fins at the aft end of the rocket are set at a slight angle to maintain the spin.

In 1956 an accelerated development program began on a smaller ballistic rocket, resulting in the Little John. It was developed especially for use with airborne infantry divisions. Little John is 14.5 ft. long, 12.5 in. in diameter and weighs 760 lb. It has a range of approximately 10 mi. and can carry either a high-explosive or a nuclear warhead. Like the Honest John, it is a highly flexible, solid-propellant weapon. Unlike the larger rocket, Little John is spin-stabilized by the launching rail as it is fired; the spin is maintained by slightly offset fins.

During the same period of development following World War II the U.S.S.R. produced its T-5 series of large, solid-propellant, ballistic rockets. The earliest model, the T-5, was first observed in 1957. It was obviously developed from the German *Rheinbote* of World War II. A four-stage, fin-stabilized rocket, it has a range of about 100 mi. It is 32.1 ft. long, 34 in. in diameter and weighs 4,850 lb. The later T-5B and T-5C are single-stage, fin-stabilized, solid-propellant rockets, fired from highly mobile, straight-rail launchers. The T-5B is 31 ft. long and weighs 6,000 lb. It has a range of about 20 mi. The T-5C is 25 ft. long, 13.1 in. in diameter and weighs 4,400 lb. With a range of approximately 15 mi., it could carry a nuclear warhead.

Between the end of World War II and the 1960s the development of smaller solid-propellant rockets spread to other countries, primarily because of the effectiveness of such weapons. Thus by the 1960s Argentina, Italy, Japan, Sweden and Switzerland were developing and producing antitank and battlefield-support rockets.

Surface-to-Surface Guided Missiles.—The first practical surface-to-surface guided missile was based upon two sources of activity in the 1920s and 1930s. These were the theoretical work of scholars such as Tsiolkovski, Goddard, Oberth, Sänger and Esnault-Pelterie, and the experimental activity of Goddard and the amateur rocket societies. With their minds on manned interplanetary flight only, the rocket societies of Germany, U.S.S.R., U.S. and the U.K. performed an important function in proving that liquid propellants could achieve their potential in rocket motors but that the technology required would be sophisticated and costly. The theoretical work of Tsiolkovski was largely unknown outside of the Soviet Union. Oberth was actively associated with amateur rocketry in Germany, but in the United States Goddard worked by himself.

In Germany the work of the society Verein für Raumschiffahrt attracted the attention of army Col. Walter Dornberger. In 1932 he hired young Wernher von Braun, who had been active in the experimental work of the German rocket society, and a few others and began experimenting at the artillery proving ground south of Berlin. Eventually, the vast army rocket test, development and production site at Peenemünde arose under the military leadership of Major General Dornberger and the technical direction of Von Braun. The fascinating story of the intensive development and engineering of the A-4 (popularly known as the V-2) is recorded in Dornberger's book, *V-2* (1954). The term V-2 stands for *Vergeltungswaffe zwei* ("vengeance weapon two").

The V-2 rocket was nearly 47 ft. long, had a cylindrical diameter of 5.5 ft. and weighed about 27,000 lb. at takeoff. The one-ton warhead contained 1,654 lb. of high explosive. Propellants were liquid oxygen and a 75% ethyl alcohol-water mixture. Approximately 8,400 lb. of alcohol and 10,800 lb. of oxygen were burned at a rate of 300 lb. per second. The rocket motor produced 55,000 lb. thrust for about one minute at which time the engine was shut off by an integrating gyro system. Propellant supply was by turbopump, driven by high-strength hydrogen peroxide decomposed by a catalyst. Yaw and pitch control was accomplished by two pairs of graphite-carbon vanes in the rocket exhaust. Ignition of the alcohol-liquid oxygen propellants was effected by a pyrotechnic pin wheel inserted in the motor. Estimated maximum range was about 200 mi.

The first operational V-2 was fired against Paris on Sept. 6, 1944. Two days later the first of more than 1,000 missiles was fired against London. The missile traveled on a ballistic arc trajectory reaching a maximum speed of more than 1 mi. per second and an altitude of 60 to 70 mi. Since the warhead approached the target faster than the speed of sound, there was no warning of the approach of the bomb. By the end of World War II about 4,000 of these missiles had been launched from mobile bases against Allied targets in England and on the European continent. During February and March 1945, only weeks before the war ended, an average of 60 missiles was launched weekly.

Although the V-2 did not become a decisive weapon, it was nevertheless a monumental engineering achievement. Large rocket motor developments after World War II, in both the U.S. and the U.S.S.R., were outgrowths of the V-2 engine design.

The only other relatively long-range, surface-to-surface guided missile to see action in World War II was the V-1 or "buzz-bomb," a development of the German air force. The V-1 has been called, from an engineering point of view, "a perfect counterpart of the naval torpedo." The analogy is striking in several ways. Once the V-1 was launched, its course could not be corrected, being determined by a preset guidance system. An accelerometer sensed deviation to the left and right of the programmed flight path and sent corrective signals to the control surface actuators. The missile's altitude was sensed and maintained in a similar manner by a barometer, and range was determined by the number of revolutions turned by a small propeller in the nose of the missile. When the requisite number of revolutions, corresponding to a linear range, had been made, a signal was sent to the aerodynamic control surface actuators to cause the V-1 to dive vertically onto the target. The average range of the weapon was 150 mi. Launching ramps and a hydrogen peroxide-powered catapult boosted the V-1 to flying speed.

The V-1 used a unique pulse-jet engine that found later employment in early post-World War II Soviet and U.S. missiles. Air enters a diffuser through a series of spring-loaded flapper valves that open as the air passes through them and then close when the air is in the combustion chamber. At this point in the firing cycle, kerosene from a gas-pressurized tank is sprayed into the chamber and ignited by a spark plug. As the chamber pressure of the burning gas rises, the flapper valves close and the exhaust gases are forced through the nozzle of the motor. The warhead of the V-1 consisted of a 2,200-lb. charge of high explosive set off by an impact fuze.

A final, but significant, weapon under development by the Germans during World War II, and one that spurred investigation in Great Britain, France, the Soviet Union, the United States and Switzerland, was the X-7 antitank missile. Although this missile was not developed in time for use in combat, its technology set the pattern for practically all antitank guided missiles developed during the next 20 years. The X-7 was a solid-propellant winged rocket with a shaped-charge warhead and a range of about half a mile. This missile was to have been guided in flight by means of corrective signals sent over two wires trailing from its wing tips to spoilers located on the wings, similar to the X-4 air-to-air missile. The operator visually followed the missile in flight and sent corrections by means of a radio-controlled guidance set.

When World War II came to a close in Aug. 1945, development and production of rockets was a massive enterprise in the United

TABLE I.—*Surface-to-Surface Missiles*

Name and Designation	Country and service	Length (ft.)	Diameter (in.)	Takeoff wt. (lb.)	Range (mi.)	Engine(s) and Propellant(s)	Thrust (lb.) (by stage)	Remarks

*Reliable figures are not available.

States and Great Britain. Despite a few ingenious uses of rocket power, however, the major effort was conservative and on conventional lines, adapting technical improvements to existing weapons. Nowhere was there the depth of appreciation and scope of plans for guided missiles or long-range ballistic rockets that there was in Germany. Recognition of the potential of rocket power by the Allied powers came too late in the war to catch up with German developments in rocket technology.

Appreciation of the potential importance of German technical efforts was evidenced by the speed with which technical intelligence teams followed close behind front-line troops as they moved across Germany. Intensive and intelligent work on the part of these teams resulted not only in obtaining masses of technical data, design drawings and missiles but also an opportunity for interrogation of key scientists and missile engineers. The top planning and technical staff of Peenemünde, headed by Dornberger and Von Braun, fled south in the last few days of the war in order to surrender to U.S. troops. Thus the priceless experience of the German rocket effort and the knowledge of about 150 rocket experts became available to the Allies. The Soviet troops that captured Peenemünde found mostly wreckage and had orders to destroy what was left. However, the Soviets took many German technicians to the U.S.S.R. and the exchange of technical and scientific data continued until a few years later. Thus the U.S., France, Great Britain and the U.S.S.R. all had the benefit of information on rockets and guided missiles captured in Germany.

In general, early postwar development of rockets followed most of the lines suggested by German work. Rockets were used to propel all varieties of guided missiles, competing successfully in these missions with air-breathing jet engines. Refinement of all components of these systems and improved technology based upon extensive research programs have resulted in rocket-powered weapons of immense capabilities.

Not only did the U.S. obtain the services of top German rocket experts but also, from the underground V-2 factory at Niedersachswerfen, 300 boxcar loads of components of V-2 missiles—enough for about 100 complete vehicles. About 70 V-2s were fired during the period 1946–51 at White Sands (N.M.) proving ground. These firings provided much experience in handling and launching large rockets.

The long-range ballistic missile was not a major development in the U.S. until 1954. Until that time air-breathing subsonic missile developments such as the Snark and Navaho were counted upon by military planners to supplement and supersede long-range, strategic-bomber aircraft. These vehicles were essentially unmanned, turbojet engine-powered, high-speed aircraft equipped with warheads. A 75-mi.-range Corporal developed by the U.S. army with a mobile launcher was operational by this time as a battlefield support weapon.

In 1954 two developments put the intercontinental ballistic missile (ICBM) in a new light. One of these developments was the thermonuclear bomb with destructive power measured in megatons (millions of tons of TNT equivalent). The other was the miniaturization and refinement of inertial guidance systems so that they became sufficiently accurate to place the warhead of the ICBM close to a target 5,000 or more miles distant.

The first ICBM authorized was the Atlas, followed later by the Titan. The Atlas was a 1½-stage vehicle. Whereas a 2-stage vehicle drops both first-stage rocket engine and tankage, the 1½-stage vehicle drops only the rocket engine and the second stage continues to use the original tankage. The first Atlas was fired full range from the Cape Canaveral (now Cape Kennedy), Fla., missile range in Nov. 1958. The Titan was a conventional two-stage vehicle. The first successful tests of the Titan were not made until 1959. Both the Atlas and Titan burned liquid oxygen and hydrocarbon fuel (similar to kerosene).

A major logistic problem in ballistic missiles using cryogenic propellants such as liquid oxygen is the necessity for fueling just prior to launching. This weakness, which means delay in defensive, retaliatory fire, can be eliminated by the use of solid propellants or storable noncryogenic propellants. A later version of Titan used a higher-performance propellant combination of nitrogen tetroxide and hydrazine-based fuel. This propellant combination permits the missile to stand ready, fully loaded for firing.

Development of solid propellants to a level of performance near that of liquids achieved such progress by 1958 that a solid-fueled ICBM, the Minuteman, was authorized. This ICBM would be launched from underground "silos" in so-called "hard" launching sites relatively impervious to attack.

The U.S. navy became interested in long-range missiles as early as 1947 when it demonstrated that a V-2 could be launched from the deck of a ship at sea. At first the navy co-sponsored the development of the U.S. army's Jupiter intermediate range ballistic missile (IRBM), with the idea of using it aboard ships. But the problems associated with the production and storage of liquid propellants aboard ships soon turned the navy toward a quest for a solid-propellant IRBM. In Jan. 1957 the navy announced plans for a solid-propellant missile to be known as Polaris. The first test vehicle was launched in Jan. 1958, and the first underwater firing occurred in April 1960. The Polaris entered operational service aboard nuclear-powered submarines in 1961.

Ten years after World War II, the U.S. air force and army each undertook the development of an IRBM. The air force Thor and the army Jupiter both used the same liquid-propellant engine and had a range of 1,600 mi.

IRBM and ICBM developments in Great Britain and the Soviet Union paralleled U.S. efforts in the years immediately following World War II. In 1956 the British began developing the Blue Streak IRBM, with some technological aid from the U.S., but later canceled the program. The Soviets fired several captured V-2 missiles from their rocket proving ground at Kapustin Yar in 1946 and 1947 and presumably learned much from them. Early research and development models of the T-series of IRBM's were fired from this range in the late 1950s. During the 1960s ICBM's and space vehicles were launched from Tyuratam.

Regardless of the country of origin, all IRBM's and ICBM's are equipped with either nuclear or thermonuclear warheads because (1) it is economically impractical to use such an expensive missile to deliver a relatively small amount of high explosive; and (2) the unavoidable inaccuracies in range and direction make essential the far-reaching effects of a nuclear explosion.

Underwater-Launched Missiles.—A small group of surface-to-surface missiles includes those launched by submarines. The torpedo is actually a guided missile and the oldest form of this weapon. Originally these weapons followed a preset guidance course of fixed depth and carried a warhead that exploded on impact. Later versions after World War II contained seeking and acoustic homing devices designed to steer the torpedo to its target, whether submerged or on the surface. By the mid-1960s the U.S. had placed in operation the Subroc missile. Launched by a submerged submarine, the Subroc breaks surface and is propelled by rocket power on a ballistic trajectory toward an enemy submarine. Reentering the water, the missile then assumes the role of a homing torpedo.

2. Surface-To-Air.—The major purpose of the class of surface-to-air weapons is to intercept and destroy enemy aircraft, particularly at altitudes beyond the effective capability of conventional antiaircraft artillery. During World War II high-altitude bombing above this range necessitated the development of rocket-powered weapons.

Free-flight Rockets.—Except in Germany, military rocket research during the period between the world wars was limited or nonexistent, but as war began to approach, rocketry assumed new importance. In Great Britain, as mentioned above, development of rockets was headed by A. D. Crow. Initial effort was aimed at achieving the equivalent destructive power of the 3-in. and later the 3.7-in. antiaircraft gun. Single, double and then multiple launchers were produced. Massed batteries of launchers fired salvos of as many as 128 rounds.

Two important innovations were developed by the British in connection with the 3-in. rocket. Both devices were directed against the German dive bombers. One was a rocket-propelled aerial-defense system. A parachute and wire device was rocketed

aloft, trailing a wire which unwound at high speed from a bobbin on the ground. Altitudes as high as 20,000 ft. were attained. Several versions of this were used, quite successfully, from ships. The other device was a type of proximity fuze utilizing a photoelectric cell and thermionic amplifier. Change in emission of light from a nearby airplane (projected on the cell by means of a lens) triggered a thyratron and the detonating train of the shell.

The only significant antiaircraft rocket development by the Germans was the *Taifun*. A slender 6-ft. liquid-propellant rocket of simple concept, the *Taifun* was designed to be launched to altitudes of 50,000 ft. Planned for mass production, the design embodied coaxial tankage of nitric acid and a mixture of organic fuels. This weapon, however, was never put into operational use.

Surface-to-Air Guided Missiles.—During World War I an attempt was made by Great Britain to substitute gyrostabilizing equipment, automatic and radio control for a human pilot in small propeller-driven aircraft. This aircraft was actually flown, but its speed, range and accuracy were marginal. The aim was a weapon to combat Germany's dirigible bombers.

During World War II Germany made efforts to produce effective surface-to-air missiles. Three of those under development were subsonic; the *Schmetterling* and *Enzian* resembled stubby midwing aircraft, and the *Rheintochter* had cruciform wings. All used solid-propellant boosters, or takeoff rockets, and sustainer motors, except that there was a liquid-propellant version of the *Rheintochter*. Altitude capability was about 50,000 ft. The *Wasserfall* was a superior weapon designed to operate at supersonic speeds. A single-stage missile weighing 8,400 lb. at takeoff, this weapon was powered by a 17,000-lb.-thrust motor at a velocity of 2,500 ft. per second. Maximum altitude was 60,000 ft., and the weight of the warhead was 330 lb. Propellants were nitric acid and vinyl isobutyl ether. All of these weapons would have had important effects upon enemy aircraft flying at 15,000 to 30,000 ft. However, none of them ever became operational. In no other country, however, had such weapons gotten beyond the planning stage. Also, the goal of launching missiles guided by radar beams had been proven technically feasible.

Following World War II the major nations continued the development and refinement of antiaircraft guided missiles. In the United States the U.S. navy initiated a research program the purpose of which was to develop a ramjet engine suitable for use in a high-performance antiaircraft missile. Ultimately, the Talos, Terrier and Tartar missiles resulted. During the same period, development continued on two antiaircraft missiles that were originally designed in the latter days of the war, the Lark and the Little Joe. The former was a 14-ft.-long, liquid-propellant weapon with semiactive radar homing. Weighing 1,200 lb., it was accelerated to operational speed by two solid propellant jato (jet-assisted-takeoff) units. It could deliver a 100-lb. warhead to a range of 38 mi. The Little Joe was an 11-ft.-long, solid-propellant missile with a range of 2.5 mi. Its payload was a 100-lb. warhead designed to counter Japanese kamikaze attacks on U.S. navy ships. Neither weapon was used in the Korean War.

*Reliable figures are not available.

The U.S. army concentrated its efforts in the field of antiaircraft weapons on the Nike group of missiles. The first of these was the Nike-Ajax, which was first test fired in 1951 and which remained deployed with the army until 1961. The missile is 21 ft. long, 12 in. in diameter and weighs 2,455 lb. With a range of 25 mi., it has a liquid-propellant engine that gives it a velocity of 1,500 m.p.h.

An advanced version of the Ajax was conceived in 1953. Known first as Nike B, the name Nike-Hercules was later used. The Hercules is 27 ft. long, 31.5 in. in diameter and weighs 5,000 lb. It has a solid-propellant motor, can carry both nuclear and high-explosive warheads, and has a range of 75 mi. Both the Nike-Ajax and the Nike-Hercules employ radar-command guidance.

Out of the early experience of the Nike program also grew the possibility for an antimissile missile. The Nike-Zeus is a complex defensive weapon system designed to intercept incoming ICBM warheads and destroy them above the atmosphere. A further development is the Nike-X, which would use some of the components of the Nike-Zeus but would also include a phased-array radar installation with electronic scanning. The Nike-X/Zeus is designed for high altitude interception, while another version, Nike-X/Sprint, is to operate at low altitudes.

Late in 1963 the U.S.S.R. announced that it had developed an effective antimissile missile. It is reported to be a two-stage weapon, 52 ft. in length.

Other significant current U.S. surface-to-air missiles include the Hawk, capable of intercepting low-flying aircraft, as is the shoulder-launched Redeye. Both have homing devices.

Atmospheric Sounding Rockets.—Despite their short lifetime atmospheric sounding rockets have become important scientific implements for several reasons. First, they are the only means of lifting scientific instruments to altitudes between 50 and 100 mi.—heights above the reach of airplanes and balloons but still within the atmosphere and thus impractical to explore with artificial satellites. Second, their size and simplicity, within limits, permit experiments, such as meteorological measurements, to be made at times and locations desired by the scientist. Third, on a weight basis, sounding rockets can lift a larger expendable power supply than artificial satellites for experiments of limited duration. Sounding rockets have investigated such phenomena as cosmic rays, solar ultraviolet radiation and X rays, auroral particles, micrometeorites and the Earth's magnetic field.

Before 1946 all upper-atmosphere research had been conducted from balloon sondes or aircraft. Beginning in 1946 various kinds of physical sensors were carried aloft in the nose cones of captured and reassembled V-2s to heights above 100 mi. In the next few years both the Aerobee and Viking sounding rockets obtained and telemetered much new scientific data. Photographs of the Earth were taken from space. Mice were carried aloft and photographed under conditions of weightlessness. Slowly the art of building these new, complex and expensive research tools developed. Attempts were made to lower costs and to achieve higher altitudes by launching rockets from high-altitude balloons (Rockoon and Project Far Side).

Typical of experiments performed by sounding rockets is one begun in 1954 that determined regions of intense turbulence and strong shear winds below the altitude of 60 mi. and extremely high winds above that altitude. These conditions were observed by Nike-Asp sounding rockets that released trails of sodium vapour into the atmosphere between 60 and 120 mi. above the Earth. Temperature measurements at high altitudes are made by timing the arrival of the sound of exploding grenades ejected from sound-

ing rockets, such as Skylark and Nike-Cajun, at altitudes between 38 and 65 mi. By the mid-1960s much of the knowledge of the temperature and pressure of the atmosphere, as well as the composition of the ionosphere, was based on data from sounding-rocket experiments.

Sounding rockets range in size, performance and cost from a simple, single-stage, solid-propellant rocket such as the 77-lb. Arcas, which can lift a 12-lb. meteorological payload 37 mi., to the two-stage, solid-propellant 1,553-lb. Aerobee 300, which can lift a 35-lb. payload to 300 mi. Liquid-propellant sounding rockets are also used extensively. The French Véronique rockets proved valuable during and after the International Geophysical Year

(IGY). First flight-tested in 1950 these rockets were subsequently flown at the French missile test range at Colomb Béchar, Alg. In its IGY flights the Véronique used an 8,820-lb.-thrust engine burning nitric oxide and turpentine. The rocket weighs 2,962 lb. and can lift a payload of 166 lb. to an altitude of 140 mi. The Véronique is 24 ft. long, 22 in. in diameter and is fin-stabilized.

Cooperative worldwide efforts during the International Years of the Quiet Sun resulted in the 1960s in several dozen coordinated rocket soundings of the upper atmosphere, which yielded new scientific understanding of solar effects upon the earth.

3. Air-to-Surface.—*Free-Flight Rockets.*—Great Britain, Germany, Russia, Japan and the United States all developed airborne rockets for use against surface as well as aerial targets. These were almost invariably fin-stabilized because of the effective aerodynamic forces when launched at speeds of 250 m.p.h. and more. Tube launchers were used at first, but later straight-rail or zero-length launchers, located under the wings of the airplane, were employed.

One of the most successful of the German rockets was the 2-in. in diameter R4M. The tail fins remained folded until launch, facilitating close loading arrangements. The U.S. achieved great success with a 4.5-in. rocket, three or four of which were carried under each wing of Allied fighter planes. These rockets were highly effective against motor columns, tanks, troop and supply trains, fuel and ammunition depots, airfields and barges. The largest U.S. airborne rocket was the Tiny Tim. More than 10 ft. long and 1 ft. in diameter, it carried 150 lb. of TNT. The solid-propellant motor developed 30,000 lb. of thrust for 1 sec.

A variation on the airborne rocket was the addition of a rocket motor and fins to conventional bombs. This had the effect of flattening the ballistic trajectory, extending the range and increasing the velocity at impact, useful against concrete bunkers and hardened targets. These weapons were called glide bombs, and the Japanese had 815-lb. and 224-lb. versions. The U.S.S.R. employed 56-lb. and 220-lb. versions from the Stormovik fighter aircraft.

Air-to-Surface Guided Missiles.—Among the first air-to-surface guided missiles, developed by the Germans, was the radio-controlled, armor-piercing Fritz-X, which sank the Italian battleship, "Roma," after its surrender to the Allies in 1944. Another was the Hs-293 winged bomb. More than 11 ft. long and weighing about 1,700 lb., this radio-controlled weapon destroyed a number of merchant ships in Allied convoys. Although these early versions of glide bombs required optical tracking (and, therefore, clear weather), plans were under way for television viewing of the target by the weapon and radar spotting for nighttime and foul-weather use. The U.S. developed a controlled glide bomb called the Bat, similar to the Hs-293. Although not employed until the closing months of the war, it was credited with sinking a Japanese destroyer at a range of about 20 mi.

The Hs 293 was a radio-guided bomb with a rocket engine using hydrogen peroxide as a propellant. This chemical was decomposed into steam by the use of aqueous potassium permanganate as a catalyst. A crew of three, a pilot, an observer and a bombardier, were necessary to launch and direct the Hs 293 to its target. The observer's duty was to set the gyroscope that established a reference plane for the missile, and the bombardier piloted the bomb by remote control after its release from the aircraft. It was especially adaptable to targets at sea and found its greatest use there, sinking many merchant ships.

The American Bat had a much greater range—up to 20 mi. In guidance it was in advance of the Hs 293 since it employed an active radar homing device. The Bat was a glide bomb, however, having no propulsion system. It weighed 1,000 lb. and was 12 ft. long with a wing span of 10 ft. Developed primarily as a weapon for use against ships, the Bat was to be released from an airplane at an altitude of 3 to 5 mi. The bomb's velocity of 300 m.p.h. was considerably slower than the 470-m.p.h. Hs 293. Built in considerable numbers prior to the end of the war, the Bat was not actually used until April 1945. Even at that late date, however, it was credited with sinking a Japanese destroyer at the maximum range of 20 mi.

TABLE IV.—*Air-to-Surface Missiles*

Name and Designation	Country and service	Length (ft.)	Weight (lb.)	Range (mi.)	Engine(s)

*Reliable data not available.

After 1945 the U.S. air force explored more complex versions of the air-to-surface missile. One of these was the Rascal, a liquid-propellant missile with inertial guidance and a range of 100 mi. By the mid-1950s development turned to achieving longer ranges. This effort was aided by the advent of lighter-weight nuclear warheads. Two of the weapons developed, the U.S. Hound Dog and the British Blue Steel, had ranges of about 200 to 600 mi. The Skybolt, canceled in 1963, was to have had a range of 1,000 mi. The cause of the cancellation was essentially the difficulty in guidance from an aerial launch; development was stopped in favour of alternative weapons, such as the fixed-base ICBM.

The complexity and expense of air-to-surface missiles is great. Particularly difficult is the guidance problem. It was found that at extreme ranges, programmed and command systems were not feasible and that it was necessary to rely on such delicate and exacting systems as stellar guidance, usually in combination with inertial guidance.

4. Air-to-Air.—*Free-Flight Rockets.*—One of the earliest weapons concepts in this category was that of Swedish Lt. Col.

Baron von Unge. He proposed the use of his improved Hale-type, spin-stabilized rockets as armament for dirigibles in 1908, calling them aerial torpedos.

As might be suspected, aircraft-launched rockets can be used against aerial as well as ground targets, provided that the aerial targets are propeller-driven aircraft with a speed of 400 knots or less. Near the end of the war the German Me 262 jet fighter carried 48 such rockets. On one sortie, six Me 262s shot down fourteen B-17s during a daylight raid, without the loss of one fighter aircraft.

After World War II the U.S. fitted many aircraft with 2.75-in. Mighty Mouse and Aeromite rockets. Developed by the navy and later adopted by the air force, the AD (Skyraider), F-80 (Shooting Star), F-86D (Sabre) and F-89D (Scorpion) aircraft were equipped with launchers. Firing could be singly or in clusters. Another postwar development by the U.S. was a version of the army's 5-in., spin-stabilized rocket loaded by belt and fired from within the wing of the Skyraider.

Other countries fitted airborne rockets to aircraft for air-to-air weapons, notably Sweden (Gerda, 3 in., 15.5 lb.), Italy (2.4 in., 7.9 lb.) and Switzerland (3.15 in., 22 lb.).

Air-to-Air Guided Missiles.—As in the case of other guided missiles, Germany led in the development of the air-to-air category, although similarly, the weapon—called the X-4—never reached operational use. An ingenious design, the X-4 was 6.5 ft. long, 8.6 in. in diameter and weighed 132 lb. It had two sets of cruciform wings and fins. Two opposing wings carried pyrotechnic guide flares, and the other two carried streamlined bobbins, which trailed as much as four miles of fine copper wire. Along these wires traveled corrective directional signals which automatically imparted drag to the rear fins while the vehicle, traveling almost 600 m.p.h., spun slowly. The X-4 was powered by a nitric acid-organic fuel rocket motor and carried a 44-lb. warhead.

TABLE V.—*Air-to-Air Missiles*

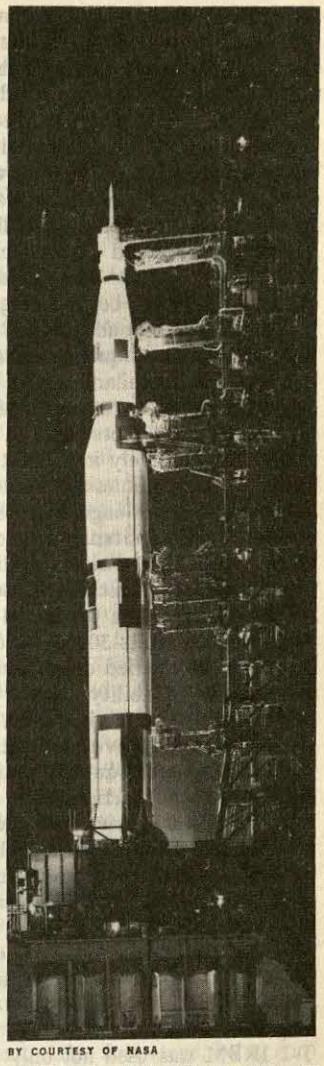
*Reliable data are not available.

After World War II the first U.S. air-to-air guided missile was the Firebird. It was 10 ft. long, had a solid-propellant booster, a liquid-propellant sustainer motor, was aimed initially by radar from the launching aircraft and homed on the target, guided by an on-board radar system. First test-launched in 1947, the Firebird was considered obsolete three years later. It was replaced by more sophisticated, supersonic missiles, such as the Sparrow, Falcon and Sidewinder. Similarly, the British developed the 14-ft. Red Dean with a range of 5 mi. which was canceled in 1957 in favour of the Firestreak and Red Top missiles, which had infrared homing guidance. Fired from a pursuit course, these missiles tracked the hot exhaust gases of the target plane and literally flew into its tail. By the late 1960s air-to-air guided missiles had achieved velocities of Mach 3 at ranges of more than ten miles. Such improvements were necessary to keep pace with supersonic aircraft. (F. C. D. III)

5. Space-Launch Vehicles.—Rocket-powered vehicles used to launch spacecraft beyond the Earth's atmosphere are known as space carrier vehicles. Their development became possible only after atmospheric sounding rocket and ballistic missile technology had reached a high level of reliability, and after launching and handling techniques had been well proved. The first small space carriers, fired in the late 1950s, were derived from such sounding rockets as the Viking and such ballistic missiles as the Redstone.

The Viking and the Redstone could handle rather heavy payloads for low-altitude, moderate-range missions at velocities of 4,000 to 5,000 m.p.h. With relatively small payloads, on the other hand, these two carrier vehicles attained higher altitudes and much greater velocities: approximately 18,000 m.p.h. To provide the capability for their more difficult missions, the carriers required powered upper stages, which fired consecutively after the burnout of the next lower stage.

Inevitably, small space carrier vehicles were followed by larger versions. The latter were based on proven military ballistic missiles such as the Jupiter, Thor, Atlas and Titan. Giant space carriers, such as the Saturn 1 and Saturn 5, are not directly based on military missilery but they do owe a great debt to it. Virtually every advance in propulsion, guidance, control, telemetry, structural design, handling and launching has been made in response to original military requirements.



BY COURTESY OF NASA

SATURN 5, VEHICLE, 365 FT. IN HEIGHT, USED FOR TRAINING

It is conventional to divide space carriers into a number of categories: (1) small carriers; (2) carriers based on intermediate range ballistic missiles; (3) carriers based on intercontinental range ballistic missiles; (4) large carriers; and (5) air-launched carriers. Vehicles in the first four categories are launched from the surface of the Earth and those in the fifth category are fired from balloons and airplanes.

Small Carriers.—The space exploration program initiated by the United States in the mid-1950s was based entirely on small space carrier vehicles, whose first stages developed between approximately 25,000 and 125,000 lb. of thrust. The major U.S. small space carrier vehicles included the Argo series, the Astrobee 1500, the Blue Scout series, the Scout and the Strongarm. As far as is known, the Soviet Union has not employed small space carrier vehicles, although it designed, developed and fired many atmospheric sounding rockets.

Britain has used its Black Knight ballistic test rocket in a modified space carrier role. The vehicle is available in both one- and two-stage versions and can reach altitudes between 300 and 500 mi. The French space carrier, the Diamant, is designed to orbit 100-lb. satellites from 200 to 250 mi. above the Earth. This carrier weighs about 36,000 lb. and develops the following thrusts: first stage 56,000 lb.; second stage 30,000 lb.; and third stage 10,500 lb.

Small carriers are conveniently divided into those powered by liquid-propellant engines and those powered by solid-propellant engines. The first liquid-propellant rocket carrier vehicle to be developed was the Vanguard; however, the first successful firing of a carrier belonging to this category was the Juno I, the launch vehicle for the first U.S. artificial satellite, Explorer 1. Juno I consisted of a modified Redstone medium-range military ballistic mis-

sile with three upper stages powered by solid-propellant engines. To become effective as a first stage in the satellite launching application, the tanks of the Redstone had to be lengthened about 8 ft. to accommodate additional fuel. The second stage consisted of a cluster of 11 small, solid-propellant engines arranged in a cylindrical tublike configuration with a webbed base-plate. Mounted inside the 11 motors were the three motors of the third stage. Finally, inside these motors was the fourth-stage motor, to which was attached the satellite payload.

The Juno I could place satellites weighing from 30 to 40 lb. into 200-mi. orbits. The carrier orbited three Explorer satellites out of six attempts before being retired from service in Oct. 1958.

The first and second stages of the Vanguard space carrier vehicle were powered by liquid-propellant engines and its third stage by a small solid-propellant engine. A long, slender, finless carrier, it was designed solely to serve as a space carrier vehicle and was not, like the Juno I, adapted from a military missile. Aluminum sheet was used extensively in its first stage construction, while the second stage had stainless steel monocoque tanks, aluminum frames and stringers, and magnesium-thorium skin. An asbestos phenolic nose cone with a titanium tip capped the reinforced-plastic third stage. Although considerably lighter than the Juno I, and with a first-stage engine which developed only about one-third the thrust, the advanced design permitted Vanguard to lift 100-lb. satellite payloads into orbits 300 mi. above the Earth. Because Vanguard was based on untried components and new, unproven techniques, it had a low reliability; out of 11 firings it succeeded in orbiting only a small test satellite and two full-scale satellites. Vanguard was retired from service in Sept. 1959.

Small carriers powered entirely by solid-propellant engines largely replaced carriers with liquid-propellant engines. Small, solid-propellant carriers offer economy and rapidity of operation, and ease and flexibility of launching. They are principally utilized for vertical probing missions up to several thousand miles from the Earth. Some, however, can place small satellites into orbits close to the Earth.

IRBM-Based Carriers.—The most widely used carriers are those based on intermediate-range ballistic missiles. In the United States both the Jupiter and the Thor IRBM's have served as first stages for two- and three-stage carriers. In the Soviet Union the T-2 IRBM was used not only as a satellite carrier but in many vertical geophysical exploration flights.

The vehicle Juno II consisted of a Jupiter first stage and the same upper stages as used with the Juno I. To permit a longer burning time, the Jupiter's tanks were lengthened by 3 ft. The instrumentation compartment was located above the tanks, followed by an interstage structure and finally the upper-stage cluster. A shroud protected the upper three stages and the payload from aerodynamic heating.

The Juno II was capable of placing a 100- to 110-lb. payload in a 300-mi. orbit and of "escaping" (*i.e.*, ejecting from the Earth's gravitational field) slightly more than 15 lb. Prior to being retired from service in May 1961, the Juno II had been fired ten times. It orbited three 85- to 95-lb. scientific satellites and took the 15.25-lb. Pioneer 4 past the Moon and into heliocentric orbit.

Six space carrier vehicles using the Thor IRBM first stage have been developed and fired. They are the Thor-Able, the Thor-Agena A, B and D, the Thor-Delta and the Thor-Epsilon. In order to prepare the Thor for its carrier application, unnecessary military components are removed, interstage structure is added, and the warhead-type nose cone is replaced by a payload of instruments.

The first Thor-based carrier was the three-stage Thor-Able, derived from the two-stage Thor-Able re-entry test vehicle. Its liquid-propellant second stage was modified from Vanguard's second stage, while the third stage was powered by Vanguard's X-248 solid-propellant motor. For some firings a small fourth-stage engine was attached to the payload to effect trajectory corrections and orbital maneuvers. As an example, in the early Pioneer program a small solid-propellant rocket motor was incorporated to correct the lunar approach velocity; and in the Explorer 6 program a 440-lb. thrust "kick rocket" provided a means of increasing the perigee.

The Thor-Able could place approximately 350 lb. into a 300-mi. orbit and 95 lb. onto an escape trajectory. Until it was retired from service in the spring of 1960 it had orbited three satellites in three launchings and had placed a probe 70,700 mi. from the Earth. Its major accomplishment was the launching of Pioneer 5 into an interplanetary trajectory.

The two-stage Thor-Agena A could place 1,700-lb. satellites into orbits with minimum altitudes of 100 to 200 mi. The second stage weighed 8,600 lb. loaded and 1,700 lb. empty; this latter weight represented that of the Discoverer satellite payload, which in effect was the empty second stage. The guidance system was incorporated into the second stage and included an inertial reference package, an accelerometer-integrator, a pneumatic jet control system and a hydraulic control system. The sensor of the jet control system was an infrared horizon scanner. The Thor-Agena A is no longer flown.

The major differences between the Thor-Agena A and the Thor-Agena B are that the latter's second stage contains approximately twice the amount of propellant and also has an engine that is capable of being restarted in space; *i.e.*, it can be turned off and reignited for effecting precise orbital control. The capabilities of the Thor-Agena B are greater than those of the Thor-Agena A; *e.g.*, it can place 2,100-lb. Discoverer satellites into approximately the same polar orbits as the earlier carrier and also can lift 850-lb. payloads into 1,200-mi. orbits. As with the Agena A, it is used exclusively for orbital missions. Most of its firings have occurred in the air force Discoverer series, but it also successfully placed the NASA-Canadian Alouette 1 satellite into orbit. The Thor-Agena D has approximately the same capabilities as Thor-Agena B, but is slightly shorter in length.

The Thor-Delta is essentially a modernized version of the Thor-Able. During its successful firing history the system was gradually improved in performance capabilities, especially with the introduction of a more powerful Thor first stage (the original model produced 150,000 lb. of thrust compared with the later model's 170,000 lb.). Roll and pitch programmers are carried into the first stage and a radio command system is utilized for second-stage guidance.

Early models of the Thor-Delta were capable of placing 500-lb. satellites in orbits at 300-mi. altitudes, while the later model placed satellites of the same weight in 500-mi. orbits. Lighter payloads can be lofted much higher; *e.g.*, the 79-lb. Explorer 10 had an initial perigee of 110 mi. and an apogee of 112,500 mi. The Thor-Delta has been successfully used in the Echo, Tiros, Explorer, Ariel, Telstar, Orbiting Solar Observatory and Relay satellite programs.

Thor-Epsilon, also known as Thor-Able-Star, is a two-stage rocket that has been used successfully in the Anna geodetic, Courier communication, Transit navigation and various scientific research satellite programs. The Thor-Epsilon is designed to place payloads weighing as much as 800 lb. into 300-mi. orbits and those weighing 500 lb. into 700-mi. orbits. The most recent Thor-based carriers are given lift-off boost by three solid-propellant rockets strapped to the first stage. These motors develop 55,000 lb. of thrust each and increase greatly the carrier's lifting capability.

During a typical flight the second stage of the Thor-Epsilon burns for about 285 sec. following the burnout of the first stage. After the burning period the engine is shut off and the attitude of the stage is precisely controlled by eight small jet nozzles operating on pressurized nitrogen. Following the coasting period the second-stage engine reignites for 10 or more seconds to place the payload in the exact orbit desired.

For many years the British studied space carrier designs utilizing their Blue Streak IRBM, which was developed for, but never placed into, military service. The Blue Streak is somewhat more powerful than U.S. IRBM's and consequently offers a greater lifting capability when fitted with suitable upper staging. Studies made in the late 1950s suggested the incorporation of the British Black Knight test vehicle as the Blue Streak's second stage, together with a liquid- or solid-propellant third stage for high-speed escape missions. Another configuration was based on the use of

a simple, twin-rocket, solid-propellant propulsion unit in the second stage. Such a configuration would permit about 1,000 lb. of payload to be placed into orbit at an altitude of 300 mi. The configuration utilizing the Black Knight as its second stage offered about the same capability. A third configuration also was based on the Black Knight, but had considerably more propellant capacity. It would enable a 2,000-lb. payload to be placed in the same orbit. A solid-propellant rocket placed on top of this stage could be used for projecting relatively small probes farther out into space.

By the mid-1960s a plan for a European, rather than a strictly British, space carrier vehicle had made considerable progress. During 1962 the European Launcher Development organization (ELDO) was established, and headquarters were set up in Paris with the following member nations: Great Britain, France, Germany, Italy, Belgium, the Netherlands and Australia. In accordance with the ELDO convention the first stage of the carrier was to be the Blue Streak, the second stage the French Coralie based upon Véronique and the third stage a new German design. Italy was to supply the test satellite, Australia the launching site, Belgium the navigation system and the Netherlands the telemetry system.

ICBM-Based Carriers.—In the United States the Atlas and Titan ICBM's were modified to serve as carrier vehicle lower stages, and in the Soviet Union the T-3 series of ICBM's were similarly adapted. ICBM-based carriers can lift payloads weighing many thousands of pounds and have been used extensively to place unmanned and manned artificial satellites into orbit around the Earth. They have also served to power lunar, planetary and interplanetary probes along departure trajectories.

Following 15 research and development launchings between June 1957 and Dec. 1958, the Atlas ICBM was used frequently as a space carrier. Constructed of thin-gauge stainless steel, the missile must be pressurized in order to maintain its shape; it has no internal framework. It is powered by three liquid-propellant engines, two of which are mounted on the sides of the missile and drop off with their protective skirts after burnout. The sustainer engine burns for a longer period until it too shuts down. The two 1,000-lb. thrust vernier engines continue to operate, making velocity adjustments to insure accuracy in the trajectory. To modify the missile for its space carrier vehicle role, extensive structural changes were introduced into the upper section. Seven versions of Atlas space carriers are Atlas-Able, Atlas-Agena A, Atlas-Agena B, Atlas-Agena D, Atlas-Mercury, Atlas-Centaur and Atlas-Score.

The relationship between the Atlas-Agena A and the Atlas-Agena B is much the same as that between the Thor-Agena A and the Thor-Agena B. The later models incorporate a larger and more powerful second stage, permitting heavier payloads to be placed into orbit. In the case of the Atlas-Agena B, the capability is increased to permit payloads to be launched to the Moon, Venus and Mars.

The Agena A stage of the Atlas-Agena A contained a flight control system consisting of a tape-fed programmer and autopilot. Guidance commands were superimposed on the programmer signals that fed into the autopilot, gimbaling the engine thrust chambers and thereby guiding the carrier into the proper flight trajectory. Pitch and yaw control during orbital injection was provided by gimbaling the engine. Gas jets provided roll control. The second-stage engine was started by the programmer, and an integrating accelerometer determined the velocity to be gained and signaled the precise time of engine shutdown. The Atlas-Agena A was capable of orbiting 5,000-lb. satellites 300 mi. from the surface of the Earth. It was flown four times in the Midas and Samos military satellite programs.

The second stage of the Atlas-Agena B differs from the Agena A second stage in that it is larger and heavier, it carries approximately double the amount of propellants and it is powered by an engine that can be turned off and restarted in space, an important characteristic for certain orbital and deep space maneuvers. Agena D, a standardized production stage similar to the B model, replaced A and B in the mid-1960s.

The 447-lb. Mariner 2 Venus probe, launched by the Atlas-Agena B on Aug. 27, 1962, illustrates the operation of the carrier during a departure trajectory mission. In such a firing the Atlas first stage fires for approximately 5 min., first rising vertically and then pitching toward the horizontal. At a signal from the ground guidance system, the Atlas sustainer engine is shut down and the shroud covering the payload is jettisoned by eight spring-loaded bolts. Almost simultaneously, the 22-ft.-long Agena B stage separates from the Atlas and pitches down from an attitude almost 15° above the local horizon to a point nearly level with it. Once the horizontal attitude is attained the Agena B fires for the first time, burning for about 2½ min. and building up to orbital velocity (approximately 18,000 m.p.h.). At the conclusion of burning, the stage is in a 115-mi. circular temporary orbit in which it coasts for slightly longer than 13 min.

At the optimum position and time in space, the Agena B reignites and enters into an escape trajectory at a velocity of more than 25,500 m.p.h. About 2 min. after cutoff the payload is separated by spring-loaded bolts from the Agena B stage and moves toward its deep space destination. This is the injection phase.

The stage itself is made to yaw 140° in the local horizon plane and undergo a retrofire maneuver (with small jets), placing it in a different trajectory. This prevents the stage from confusing the guidance instruments on the payload, which could mistake sunlight reflected from the stage for the Sun or Earth.

The Atlas-Agena B is capable of placing 5,800-lb. satellites into 300-mi. orbits, hard-landing 750-lb. payloads on the Moon and projecting payloads weighing from 400 to 500 lb. to the vicinity of Mars and Venus. In Nov. 1964 an Atlas-Agena D launched the 570-lb. Mariner 4 spacecraft on its mission to fly by and photograph Mars.

The only Atlas-based carrier employed for manned space missions is the Atlas Mercury, also referred to as the Mercury Atlas. There are three major differences between the standard military Atlas and this carrier: (1) the payload adapter section is modified to accept the Mercury manned satellite; (2) the upper structure of the Atlas is strengthened to handle increased stresses; and (3) an abort system is incorporated to set off the Mercury escape system should an impending failure be detected in the carrier vehicle. The carrier has no powered upper stage; the Mercury satellite is placed atop the 63-ft.-long Atlas first stage, being connected by an adapter section. It is capable of placing 3,000-lb. satellites into 100-mi. orbits.

Most powerful of all Atlas-based carriers is the Atlas-Centaur. The outstanding feature of the carrier is its second stage, powered by twin 15,000-lb.-thrust rocket engines operating on the high-energy propellant combination of liquid oxygen and liquid hydrogen. It is the first known rocket to use liquid hydrogen. This high-energy combination permits about 40% more impulse per pound of propellant to be generated than with the conventional liquid oxygen-kerosene combination. It was designed to lift 8,500-lb. satellites into 300-mi. orbits, 1,200-lb. satellites into 22,300-mi. stationary 24-hour orbits, 2,300-lb. probes into escape trajectories and craft weighing nearly 700 lb. soft-landed onto the Moon.

The second, or Centaur, stage has the same 120-in. diameter as the Atlas first stage. Both stages are constructed in a similar way. To insulate the very cold liquid hydrogen from the warmer liquid oxygen, two thin steel bulkheads filled with matted fibreglass are employed. Between stages is a 13-ft.-long, 120-in. diameter interstage adapter and separation system connected to the 42-ft.-long, 32,000-lb. second stage. After burnout, stage separation is assured by retro-rockets mounted on the first stage and ullage rockets fitted to the second stage. The upper stage and payload are protected from aerodynamic forces and heating by a shield, which is discarded as the carrier leaves the outer atmosphere.

Atlas-Centaur is guided by an all-inertial system located in the second stage; it utilizes a digital computer. The system provides for guidance during the entire flight of the carrier vehicle. Each stage carries an autopilot accepting commands from the guidance system. During second-stage coasting periods, small hydrogen peroxide rockets provide attitude control.

The two Titan ICBM's, Titan I and Titan II, are capable of

serving as space carrier vehicles when suitably modified. However, because of its superior performance, only the Titan II was given a role in the U.S. space program. The military version of Titan II is 103 ft. long with two tandem-mounted, 120-in. diameter stages, the first 70 ft. long and the second 32 ft. long. They are connected by an interstage structure. Both stages are rigid-body structures with conventionally built tanks. The carrier vehicle version, with a space payload instead of a military nose cone, is 110 ft. long.

The major mission assigned to the Titan II was the orbiting of NASA Gemini manned satellites, which weigh approximately 7,200 lb. To prepare Titan II for manned missions, it was necessary to make structural changes, incorporate a malfunction-detection system and install a new radio guidance system. An Agena-type third stage was to be utilized for unmanned lunar and planetary exploration missions.

Also under development was the four-stage Titan III-C. The first stage was to consist of two-solid-propellant booster motors, each generating up to 1,200,000 lb. of thrust. The second and third stages were to be the Titan II, with a twin-chamber transtage for the fourth.

Large Space Carrier Vehicles.—Large space carrier vehicles at the present stage of astronautical development are arbitrarily considered to have first stages developing at least 1,500,000 lb. of thrust, more than three times that of U.S. ICBM-based carriers. All known large carriers are propelled by liquid-propellant rocket engines, but many design studies have been made for solid-propelled carriers and carriers with stages employing both liquid and solid engines. Nuclear and electric propulsion is also being examined for upper stages of advanced carriers.

The first known large space carrier vehicles are the U.S. Saturn 1 and Saturn 1B, the first stages of which develop 1,500,000 lb. of thrust. Both carriers use the S1 first stage, which is powered by eight liquid-propellant engines. Each engine develops 188,000 lb. of thrust and is mounted at the aft end of the carrier on a thrust frame. The tail section consists of a central barrel assembly of aluminum alloy box frames and corrugated skin panels, a fire wall and a heat shield, together with appropriate shrouding. Eight attached outriggers transmit engine thrust and vehicle support loads. The stage is 80 ft. long and 257 in. in diameter.

The Saturn 1 series is divided into Block 1 and Block 2 vehicles. The first stages of Block 1 carriers are powered by interim 165,000-lb.-thrust engines rather than standard 188,000-lb.-thrust engines; consequently, first-stage thrust for Block 1 carriers is approximately 1,300,000 lb. compared with 1,500,000 lb. for Block 2 carriers. Another distinguishing feature is the fact that Block 1 carriers do not have stabilizing fins on the first stages, whereas vehicles belonging to the Block 2 series do. Block 1 vehicles weigh approximately 925,000 lb. fully loaded and are 162 ft. in length. Block 2 vehicles weigh almost 1,200,000 lb. fully loaded and are 184 ft. long.

The early test firing of the Block 1 series was completely successful: the first flight took place in Oct. 1961, and subsequent flights occurred in 1962, 1963 and 1964. In the early flights only the first stage was used; but later tests made use of a live second stage. In 1964 a SA-6 vehicle was launched, orbiting an Apollo test satellite into a low orbit. It weighed 37,300 lb. including the empty second stage. The second stage of Saturn 1, referred to as the S4 stage, is powered by six rocket engines, each developing 15,000 lb. of thrust. The stage is 40 ft. long and about 220 in. in diameter. Powered by liquid hydrogen and liquid oxygen propellants, it is a self-supporting structure with two aluminum alloy propellant tanks. The first firing with an active second stage took place in Jan. 1964, when Saturn placed a 37,700-lb. satellite, then the heaviest ever launched, into orbit.

Control of the S4 stage is achieved by gimbaling the six engines in response to signals from the vehicle instrumentation unit. The engines are canted at an angle of 6° from the carrier's centre line and can be gimbaled about 8°. A conical aluminum thrust structure joined to the lower tank bulkhead supports the engines. Initial separation of the S1 and S4 stages is achieved by explosive bolts responding to an electrical signal. The stages are further separated by retro-rockets on the S1 stage and ullage rockets on the S4 stage. The retro-rockets slow down the S1 stage and the ullage rockets (see *Propellant Supply Systems*, below) impart a small forward acceleration to the S4 stage to ensure that the propellants cover the intake ports of the turbopump system for the rocket engines. Shortly after the ullage rockets commence firing, the S4 engines are ignited.

The Saturn 1B configuration results from the substitution of the Saturn 5's third stage for the Saturn 1's second stage. The Saturn 1's 20,000-lb. low-orbital capability is increased to 32,000 lb. by the introduction of this stage. Whereas the Saturn 1 can orbit only the command and service module elements of the Apollo spaceship, the Saturn 1B can orbit the entire Apollo spaceship (including the lunar excursion module) for Earth orbital tests and crew training. The Saturn 1B version may incorporate a third stage for Earth escape missions. Designated the S5 stage, it would be approximately 30 ft. long and 120 in. in diameter and would probably be powered by twin 15,000-lb.-thrust liquid rocket engines.

These two Saturn carriers utilize an all-inertial guidance and control system adapted from the Jupiter IRBM program. The major element of the system, known as the adaptive guidance mode, is a high-speed digital computer which incorporates advanced design and packaging techniques.

The advances from the Saturn 1 and Saturn 1B carriers to the Saturn 5 are impressive. The former possess first stages developing 1,500,000 lb. of thrust, compared with 7,500,000 lb. of take-off thrust generated by the giant Saturn 5.

The first stage of the Saturn 5, known as the S1C, is powered by five liquid-propellant rocket engines, each developing 1,500,000 lb. of thrust. This stage is 138 ft. long and 396 in. in diameter. Its liquid oxygen tank is placed forward of the kerosene tank, suction lines of the latter passing through tunnels to the former. Loaded, the stage weighs approximately 4,400,000 lb. and empty, about 280,000 lb. Four of the five engines are mounted on a 364-in.-diameter ring with the pumps positioned inward. The remaining engine is mounted rigidly along the centre line. To control the vehicle, the outer four engines gimbal in response to guidance command.

Mounted above the S1C stage is the S2 stage, about 82 ft. long and 396 in. in diameter. It features an insulated common bulkhead separating the liquid oxygen and liquid hydrogen tanks, the latter being mounted forward of the former. Stage power is furnished by five engines, each developing 200,000 lb. of thrust. As with the S1C stage, four of the engines are gimbal-mounted in a square pattern outside the rigidly mounted central engine.

Retro-rockets on the S1C stage and ullage rockets on the S2 assure clean separation of the stages. Following separation, there is a short coasting period prior to engine ignition. Hydraulic actuators attached to the outer engines permit control in the pitch and yaw planes. Moving these engines simultaneously assures roll control.

Tandem-mounted above the S2 is the S4B stage, 58 ft. long and 260 in. in diameter. It can carry about 230,000 lb. of liquid oxygen and liquid hydrogen propellants and is powered by a single engine developing 200,000 lb. of thrust.

The major mission of the Saturn 5 is to launch Apollo spaceships from the surface of Earth into orbit around the Moon, from where a manned landing can be effected. The carrier is capable of placing approximately 240,000 lb. into an Earth orbit and 90,000 lb. to the vicinity of the Moon. The Saturn 5 is also to serve as the test vehicle for a nuclear-powered third stage known as Rift (Reactor in Flight Test).

By strapping on two 1,000,000-lb.-thrust, solid-propellant booster motors to the Titan II's first stage, the Titan III, our air force standardized space launch vehicle, was created. It is the first known carrier to employ parallel staging. The air force planned to use this carrier to orbit manned orbiting laboratories (MOL). The carrier has the capability of placing 25,000-lb. payloads into low 100–150 mi. orbits and 13,000 lb. into 1,000-mi. orbits; it can also inject spacecraft weighing more than 5,000 lb. into escape trajectories.

In 1963 the first designs were revealed for a huge launch vehicle called Nova. One version of this carrier would have a first stage powered by 18 advanced F-1 liquid-propellant engines, each one developing 1,800,000 lb. of thrust. The second stage would contain three M-1 engines generating 1,500,000 lb. of thrust each; there would also be a small transtage. Such a carrier could be used for deep space missions and could place 980,000 lb. into low (100–150 mi.) Earth orbits.

Air-Launched Carriers.—Three air-launched carriers, Far Side, Caleb and Jaguar, have been developed to launch small payloads into space from balloons and airplanes. The Far Side is an obsolete, four-stage, solid-propellant carrier able to lift 3- to 5-lb. payloads from 2,000 to 4,000 mi. into space following launch from a high-altitude balloon. This carrier was fired six times in 1957. Caleb also has four solid-propellant stages and is designed to be fired from an F4D airplane flying at nearly 500 m.p.h. as high as 25,000 ft. above the Earth. It is able to place 15-lb. payloads into 300-mi. circular polar orbits.

Also solid-propelled is the three-stage Jaguar used for vertical probings following launch from B-57 airplanes. Model 2 carries 35 lb. to 500 mi. compared with Model 3's capability of lofting 35 lb. to 600 mi. The major advantages of air-launched carriers are that they can be fired from virtually any geographic position over the Earth, rather than from just a few established surface bases.

6. Drones, Decoys and Test Vehicles.—This category contains a variety of special-purpose vehicles closely related to guided-missile systems.

Drones.—A drone is basically a pilotless aircraft, usually under radio-command guidance and widely employed as a target for anti-aircraft weapons. Powered by propeller-driven, turbojet, ramjet or rocket engines, a large number of these maneuverable vehicles have been developed operating at velocities as high as Mach 2. Recovery, if the drone is not destroyed, is effected by controlled landing or by parachute. Another application of drones is for military reconnaissance. Equipped with either photographic or television cameras, the drone may be shifted from radio control to present inertial guidance and flown over targets at a relatively low speed and low altitude under operationally hazardous conditions.

TABLE VI.—*Drones and Decoys*

Designation	Country and service	Mission	Propulsion
ADM-20C (Quail)	U.S., air force	Decoy (B-52)	Turbojet
AQM-37A	U.S., navy, air force	Decoy, reconnaissance	Rocket, liquid
AQM-38A	U.S., army	Target (supersonic)	Rocket, solid
B-3	Japan, army	Target	Ramjet
BMTS	U.S., army	Target (ballistic missile)	Rocket, solid
BQM-34E (Firebee 2)	U.S., navy	Target (supersonic)	Turbojet
CT-20	France, navy	Target	Turbojet, rocket launched
CT-41	France, navy	Target (supersonic)	Ramjet, rocket launched
Jindivik	Australia	Target	Rocket, liquid
MQM-57A	U.S., army	Surveillance	Reciprocating
MQM-61A (Cardinal)	U.S., army	Target	Turbojet
NV-104	U.S.	Surveillance	Turboprop
P-2	Italy, army	Target	Reciprocating
QH-50C (Dash)	U.S., navy	Drone, antitank	Turbojet

Decoys.—The decoy is a device designed to simulate by electromagnetic radiation an aircraft or ballistic-missile warhead. The purpose is to divert defensive antiaircraft or antimissile fire. Thus a relatively small decoy can be made to appear, by electromagnetic techniques, as large as a bomber on radar screens. Or it can emit infrared and other radiation to simulate a reentering ICBM warhead. Details of such devices are not released to the general public for military reasons.

Test Vehicles.—The term test vehicle covers a variety of special-purpose rockets and missiles designed to produce data on components or design features that will ultimately be used in much more expensive missiles and rockets. They may be scaled-down versions of the eventual rocket or missile. For example, after World War II, many aerodynamic shapes were tested at subsonic and supersonic velocities under dynamic flight conditions by affixing them to the front of solid-propellant rockets. Data were obtained by optical tracking and telemetry. In the development of a satisfactory design for ballistic missile reentry vehicles, a five-stage rocket vehicle carried a scale model of the test shape to high altitudes; the final stage was then fired toward the earth, achieving the reentry velocity of an ICBM. In Project Fire, NASA in a similar manner achieved velocities equivalent to those of a lunar vehicle returning to earth. Another special test vehicle is the Little Joe solid-propellant booster. It was developed to launch the Mercury and (a larger version) the Apollo spacecraft to an altitude at which the parachute recovery system could be tested. The ingenious design and use of such special-purpose vehicles built from available components can reduce costs significantly, confirm design concepts and save precious months.

7. Guidance and Control.—Most rockets require stabilization of some sort to minimize flight-path deflection caused by wind, nonuniformity of rocket structure, rocket-jet misalignment and other factors. Also, in the case of long-range ballistic missiles or satellite launchers, it is necessary for the rockets to take off vertically, programming a pitch deflection (tilt) at some predetermined altitude and velocity. The techniques used for flight control vary according to type of mission and accuracy requirements. Radio-control or inertial-guidance (stabilized-platform) systems, or both, initiate the correction and deflection signals to the vehicle.

In the case of some barrage-type rockets, launched by the thousands, dispersion errors may be accepted because of overlapping explosive effect in the target area. Aircraft rockets are often stabilized by fixed fins located at the rear of the rocket. Folding fins which open, by inertia, after firing are also used. Short-range bazooka rockets and ballistic rockets of 5-to-10-mi. range are usually fin-stabilized. Spin-stabilization is used on some rockets. In these designs, the rocket nozzle is replaced by a series of smaller nozzles, canted at an angle to impart torque as well as thrust. A unique method of wire control, based upon the German air-to-air X-4 rocket, has been used. This technique is utilized by some antitank rockets of about 1-mi. range. Fine wire is trailed from a pair of bobbins on the fins of the rocket and command signals are given by the operator observing its flight through a telescope.

If the rocket is designed to operate at high altitudes, as in the case of sounding rockets, satellite launchers and ballistic missiles of ranges greater than 100 mi., aerodynamic forces are no longer available for control because of the low density of the air. One technique, employed first by Goddard, is to place carbon or molybdenum deflection vanes within the rocket exhaust. Usually two pairs are employed for corrections about all three axes; one pair for pitch, the other for yaw and, in opposition, for roll. In flight, deviations from flight path are sensed by gyros within an automatic control (autopilot) system, and corrective signals are sent to servomotors which operate the vanes. This deflection system may be used also to program the tilt from vertical launch to ballistic flight path. Radio command may also be used to initiate the tilt program. A modification of the jet vane method is the "jetevator," a ring-shaped deflector mounted at the nozzle periphery which rotates slightly into the edge of the rocket jet as required. Gimbal mounting of the engine, permitting the motor to swivel a few degrees in any direction, is widely used for flight-path control. This system was developed for the U.S. Viking and has been used successfully on IRBM's and ICBM's. Injection of high-pressure gas in the rocket nozzle to create a local shock wave and differential pressure is a further technique of jet deflection in use. Magnetohydrodynamic (MHD) deflection of a rocket jet is another possible flight-control concept. Since a rocket jet may be highly ionized it is conceivable that a magnetic field may induce deflection of the exhaust gases without physical contact.

Roll control (*i.e.*, rotation about the long axis) is sometimes required, particularly on larger ballistic missiles. Small jets mounted transversely on the side of the missile are commonly used for this purpose.

8. Rocket and Missile Warheads.—Rocket and missile war-

heads are conveniently divided into three categories: (1) high-explosive; (2) nuclear (or atomic); and (3) special-purpose. The first of these is generally employed on short-range, tactical weapons. While it is possible to design such warheads to produce damage by either concussion (blast) or fragmentation, most depend upon some form of fragmentation. The efficiency of high-explosive warheads is a function of the size, number, weight and velocity of the fragments produced, and the reliability of the warhead is largely a function of its fuzing system. The spray pattern of the fragments is also important and is established by the geometry of the high-explosive charge and the arrangement of the fragments upon it. Nonfragmenting, high-explosive warheads for antitank weapons usually incorporate the shaped charge to achieve maximum penetration by concentrating the blast at one point. Nuclear warheads are used primarily, but not exclusively, on the IRBM's and ICBM's since it would be uneconomical and inefficient to use high-explosive heads on these long-range missiles. Typical of such missiles are the U.S. Thor, Titan, Atlas, Minuteman and Polaris. Very long-range air-to-surface missiles, particularly the so-called standoff bombs, and some air-to-air missiles as well as certain short-range tactical or battlefield rockets and missiles also can employ nuclear warheads. The nuclear warheads may be either fission or fusion types; in the latter case they are called thermonuclear or, more popularly, H weapons. The power of nuclear warheads is indicated by comparing the release of energy of a certain weapon to an equivalent weight of TNT. Thus a 10-kiloton warhead or bomb has the same explosive force as 10,000 tons of TNT. Similarly a 5-megaton device has the force of 5,000,000 tons of TNT.

Special-purpose warheads can be used on a wide variety of guided missiles and large rockets. There are two types, chemical and biological. Chemical warheads include a number of different weapons categorized by the effect of their filler agent on the target. Incendiary types start fires; poison-gas types kill or incapacitate personnel. Biological warheads contain bacteria or other pathogens that attack human beings, animals or plants on a short- or long-term basis. (F. I. Or.; F. C. D. III)

IV. FUNDAMENTAL PRINCIPLES OF ROCKET PROPULSION

Jet propulsion—of which the rocket is one type—is based upon reaction of a body to the rearward thrust of a jet of gas. The physical principle involved was set forth in Newton's *Principia Mathematica* published in 1687. In this work are stated three laws of motion. The third law states, in its simplest form, that for every action there is an equal and opposite reaction.

A simple example of reaction propulsion is the brief flight of a toy balloon after it has been filled with air and released. The forward motion of the balloon results from the rearward expulsion of air from the balloon. The thrust does not result, as sometimes erroneously presumed, from the jet pushing against the surrounding air. The force imparted by the jet is equivalent to the product of the mass flow of the air and the velocity of the jet. In the case of a chemical propellant rocket, the jet is composed of the gaseous combustion products of the propellant mixture which is burned inside a thrust chamber and ejected at supersonic velocity through a nozzle. The gas velocity in a properly designed converging-diverging nozzle is sonic at the throat (most narrow) portion of the nozzle and becomes supersonic as it travels through the diverging (exhaust) end of the nozzle.

In mathematical terms, the propulsive force derives from the momentum of the gas and is expressed as

$$F = \frac{\dot{W}}{g} \times V_e \qquad (1)$$

where F represents thrust in pounds, $\dot{W}$ the propellant flow rate, in pounds per second, g the acceleration of gravity in feet per second per second and V_e the nozzle exhaust velocity in feet per second. More precisely, another term must be added.

$$F = \frac{\dot{W}}{g} \times V_e + (P_e - P_o)\, A_e \qquad (2)$$

where P_e is the exit pressure, P_o ambient pressure and A_e the nozzle exit area. Since P_o would be equal to zero in a perfect vacuum, it may be seen that rocket engine performance increases with altitude. Thrust ratings of upper-stage rocket engines are often given both at sea level and at operating altitudes; the latter rating is always higher. Effective exhaust velocity c may be expressed

$$c = \frac{Fg}{\dot{W}} = V_e + \frac{P_e - P_o}{\dot{W}} A_e g \qquad (3)$$

Inspection of equation (1) shows that thrust can be increased by increasing the jet velocity and/or the mass flow of propellant gases. Jet velocity is related to the heat of combustion of the particular propellants burned. This is expressed

$$V_e = \sqrt{2g\, J\, \Delta H} \qquad (4)$$

in which J is Joule's mechanical equivalent of heat (778 ft.-lb. per B.T.U.) and ΔH is the thermochemical energy of the propellant in B.T.U. per pound.

Limitations on mass flow of propellant gases arise from such design considerations as maximum temperatures and pressures feasible within permissible engine weights.

Since the kinetic energy in a rocket jet is derived from conversion of the chemical energy of combustion to directed kinetic energy, high thermochemical energy per unit weight of propellant is desired. In practice, the kinetic energy of the rocket exhaust jet may be only 40% to 70% of the theoretical heat energy from combustion of the propellant. Minor losses arise from incomplete combustion and heat lost to the thrust chamber walls. Larger efficiency losses come from unavailable thermal energy which leaves the exhaust nozzle as residual enthalpy.

An important rocket term is specific impulse, I_{sp}, which is the thrust per pound per second of propellant burned

$$I_{sp} = \frac{F}{\dot{W}} \quad \frac{\text{lb.}}{\text{lb./sec.}} \qquad (5)$$

Similarly, from equation (3),

$$I_{sp} = \frac{c}{g} \quad \frac{\text{ft./sec.}}{\text{ft./sec.}^2} \qquad (6)$$

Since the lb. and ft. units cancel out, I_{sp} is given in units of seconds. Specific impulse is related to the energy content of combustion in the following general equation

$$I_{sp} = \sqrt{\frac{2J}{g}(h_c - h_e)} \qquad (7)$$

where h_c is the enthalpy of combustion products before expansion (B.T.U. per pound), h_e is the enthalpy of combustion products after expansion (expansion at constant entropy and chemical equilibrium maintained). Calculations performed with equation (7) are called shifting equilibrium calculations.

A more convenient expression, generally accurate to within a few per cent, assumes that specific heat of the gas is constant and utilizes ideal gas relationships; *i.e.*, frozen composition calculation

$$I_{sp} = \sqrt{\frac{2R}{g} \cdot \frac{k}{k-1} \cdot \frac{T_c}{M} \left[1 - \left(\frac{P_e}{P_c}\right)^{\frac{k-1}{k}}\right]} \qquad (8)$$

where R is the universal gas constant (foot-pounds per °R. per mole), k is the ratio of specific heats C_p/C_v, T_c is the combustion chamber temperature (°R.), M is the average molecular weight of the combustion products (pounds per mole), P_e is the pressure of the gas at the exit plane of the nozzle (pounds per square inch absolute), P_c is the combustion chamber pressure. This relationship is for a fully expanded exhaust nozzle; *i.e.*, P_e = ambient pressure. From inspection of equation (8) it may be seen that specific impulse is increased by increased chamber pressure and combustion chamber temperature and lowering of molecular weight of exhaust gases.

As a rocket-powered vehicle moves, the weight (mass) of the vehicle continuously decreases as the propellant is consumed and

disappears to the rear as exhaust jet. The velocity of a rocket vehicle may be calculated approximately

$$V = c \log_e \frac{M_i}{M_f} \qquad (9)$$

where c is effective exhaust velocity, M_i is initial mass and M_f is final mass, after all propellants have been burned. The expression M_i/M_f is known as the mass ratio. The true velocity will be somewhat less in practice due to air drag and energy lost in overcoming gravity. In the design of efficient long-range rockets every effort is made to reduce structural weight to a minimum and increase to a maximum the percentage weight of the propellant. In the case of the V-2, 69% of the takeoff weight was propellants. Modern lower-stage boosters have values as high as 94%. Takeoff acceleration may vary from several g's to a few tenths of a g in large rockets taking off vertically.

The final velocity of a rocket-powered vehicle can be increased, theoretically, to any desired value by the technique of staging; *i.e.*, setting a series of rockets, one on top of the other, and firing them successively. Thus each successive stage is smaller and commences firing at a higher initial velocity. In practice, however, the complications of duplicating mechanical items, cost and reduction in reliability set a practical limit to the number of stages that are employed.

An example of the benefit of staging may be obtained from the Bumper-WAC program conducted in the U.S. in 1948–50. A WAC Corporal rocket, placed on top of the V-2, was fired after burnout of the V-2. Whereas a V-2 alone achieves a maximum altitude of about 100 mi. and a maximum velocity of 3,500 m.p.h., the Bumper-WAC sent the WAC Corporal to a velocity of 5,000 m.p.h. and a peak altitude of 250 mi. Although 1,500-mi. IRBM's can achieve the necessary velocity to reach these distances with one stage (Jupiter, Thor), ICBM's are multistaged. Likewise, satellite launching vehicles that must reach speeds of at least 18,000 m.p.h. are multistaged (Thor-Delta, Saturn 1). For lunar and interplanetary flights a minimum escape velocity of 25,000 m.p.h. must be achieved.

The efficiency of a rocket-propelled vehicle increases from zero at rest to a maximum when the velocity of the jet is reached. Thus rocket systems are inefficient at low speeds.

V. ROCKET-PROPULSION SYSTEMS

A rocket-motor or thrust-chamber assembly is composed of a combustion chamber and nozzle. The injector head is considered a part of the combustion chamber in the case of a liquid-propellant motor. The term rocket engine (liquid propellant only) refers to the motor plus associated propellant and feed system, propellant lines, valves, regulators, mounting lugs, igniter, etc. A rocket power plant refers to the complete propulsion system, including propellant tankage, pressurizing system, gimbal mounting (or jetevators, vanes, etc.), tankage-level sensing devices and associated computers, etc.

The best-known rocket motors burn chemical propellants, either solid or liquid. Combustion of the propellants provides the hot gas which is exhausted in a jet through a nozzle to the rear. Other types of rocket motors employ hybrid systems (liquid propellant burned in a solid-propellant core) and air-turborockets which utilize some ram air for part of the combustion process. Two nonchemical types of rocket propulsion systems are nuclear and electrical. These systems have received serious attention only since World War II and have particular application for space flight missions.

1. Solid-Propellant Rocket Motors.—The outstanding feature of solid-propellant motors is their relative simplicity in design. All of the propellant is contained in the combustion (or thrust) chamber, usually cylindrical, to which is attached an exhaust nozzle. An electrical or pyrotechnic igniter fires the propellant charge.

Major advantages of solid rockets lie in their condition of readiness and the reliability that results from simplicity. Disadvantages arise from a somewhat lower specific impulse range at sea level (I_{sp} of 175–250 sec.) compared with liquid-propellant motors (I_{sp} of 230–270 sec.), performance variation caused by storage temperature, and heavier rocket casing to contain combustion gases at a typical 1,000 lb. per square inch (p.s.i.) pressure.

The design configuration and chemical composition of solid-propellant charges vary widely. The charge (or grain) may burn from one end only, cigarette fashion. Or, the grain may be a hollow cylinder or have a star-shaped, interior burning surface. Important parameters of solid-propellant charge design are surface area and burning rate of particular propellant mixtures.

2. Liquid-Propellant Rocket Motors.—In this class of rocket motors, the liquid combustibles are contained in tanks and fed into the thrust chamber through an injector head by a propellant supply system. Most liquid-propellant rockets use two combustibles (bipropellant system) such as liquid oxygen and kerosene. Monopropellant systems which depend upon exothermic decomposition of a substance, such as high-strength (90%–95%) hydrogen peroxide, also exist. Such systems usually have lower performance ratings but are simpler to design.

3. Combustion Chambers.—As in the case of all components of a rocket vehicle, a premium is placed on reduction of weight to the minimum adequate to perform the necessary function reliably. Combustion chambers are usually made of metal for strength and are cylindrical or bell-shaped in configuration. Thrust chambers for solid-propellant rockets are uncooled. Burning time is usually short and the walls of the chamber are not exposed to high temperature combustion if the grain burns outward from an interior core. In the case of liquid motors, the thrust chamber volume is designed to provide sufficient time for mixing and burning of the propellants before passing through the exhaust nozzle. Closely associated with combustion chamber design for liquid motors are cooling techniques and design criteria for combustion chambers, exhaust nozzles and injectors.

Cooling Techniques.—The wall of a combustion chamber may be uncooled if the duration of operation of the motor is a few seconds only. In such a case the metal wall acts as a heat sponge or sink, absorbing heat for a short time. At least one liquid-propellant booster rocket has been designed to operate for a few seconds with uncooled walls. But liquid rockets operate usually for longer periods of time, 2–5 seconds to 5 or more minutes. To accommodate chamber temperatures of 4,000° to 7,000° F. (2,204.5° to 3,871° C.), a number of techniques have evolved. Molded ceramic liners of low thermal conductivity and high melting point have been used, but such materials are often subject to cracking from high thermal stresses occurring at the start. Another method is film cooling wherein water or a propellant is admitted through holes in the chamber and the liquid flows along the wall and absorbs heat. The most used method is regenerative cooling. In this technique, one of the propellants flows along the outside of the nozzle and thrust chamber wall before it is injected into the motor. The heat which the propellant thus absorbs is not lost but is added to the heat of combustion in the thrust chamber. Design of the cooling flow passages is critical since it is necessary to prevent boiling of the propellant and yet obtain a lightweight structure and low pressure drop. A high pressure drop results in greater design weight and higher pressure flow systems. Because the heat transfer rates to the walls are greatest in the narrow neck of the nozzle, the coolant flow rate is usually highest at this point.

In the early 1960s a new technique—ablative cooling—was developed, using materials similar to those employed as heat shields for reentering space vehicles. Rocket chamber liners and entire chambers were made of these materials, which absorb and dissipate large amounts of heat as they vaporize, and are lighter than comparable, regeneratively cooled systems. They are also useful when propellant flow rate may be insufficient for regenerative cooling (*e.g.*, low thrust levels) or when neither of the propellants has inherent sufficient cooling capacity to protect the rocket engine from heat damage.

Design Criteria.—In the design of combustion chambers for liquid rockets the following parameters are significant: thrust, pressure and temperature of combustion gases, average molecular weight and ratio of specific heats of products of reacting propellants, velocity of flow of propellants, ratio of chamber volume to throat area, nozzle interior contour or shape, duration of contin-

uous operation and chemical characteristics of propellants.

In the design of exhaust nozzles the combustion gases are expanded nearly isentropically to ambient pressure. In the case of a sounding or ballistic rocket the ambient pressure decreases with altitude. For high altitude or operation in the vacuum of space the diameter of the nozzle exit becomes very large and the construction weight prohibitively high. Thus nozzle design is usually subject to compromise, and certain reductions in efficiency (nozzle losses) are accepted.

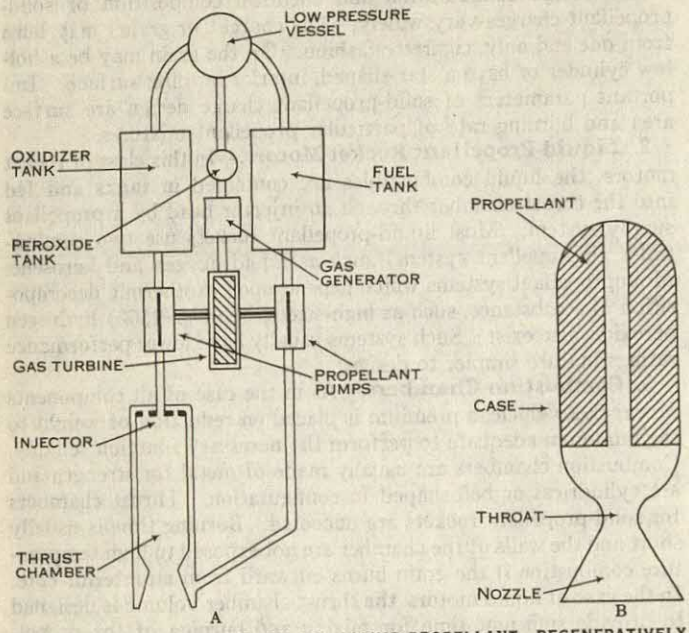


FIG. 2.—TYPICAL DESIGNS OF (A) LIQUID-PROPELLANT, REGENERATIVELY COOLED ROCKET POWER PLANT AND (B) SOLID-PROPELLANT ROCKET MOTOR

Gas pressure from the storage vessel, in a typical liquid-propellant rocket, forces high-strength hydrogen peroxide into the gas generator where a catalyst causes decomposition. Gaseous products (steam and oxygen) drive the turbine wheel which rotates centrifugal propellant pumps. Light gas pressure on propellant tanks prevents cavitation of high-performance pumps. One propellant flows directly to the rocket motor injector head; the other flows through a jacket around the combustion chamber, cooling the motor, and then through the injector. Propellants are sprayed into the combustion chamber where they burn smoothly and uniformly, exhausting in a jet through a supersonic nozzle. The solid propellant contains both the fuel and oxidizer within it. This type burns from the internal axial slot outward to the case. Early designs employed a solid-pack propulsive charge and burned cigarette-fashion from the rear toward the front end

The injector head meters the propellants at a predetermined rate and mixture-ratio, and atomizes and combines the mixture within the combustion chamber so that burning takes place smoothly and completely. The pressure drop across the injector must not be too great or an excessive burden is placed upon the propellant supply system and the weight of construction increased unnecessarily. Good injector design reduces to a minimum the volume and length of a combustion chamber. A number of types of injector design have evolved. In the impinging spray type, propellant streams in pairs or clusters are injected to intersect at high velocity so that they break up into small droplets, evaporate and burn. In the showerhead type, a series of concentric rows of holes spray the propellant into the chamber. The rows of sprays may or may not impinge. Sometimes concentric slots are used to produce intersecting conical sheets of propellant sprays.

A German (*Enzian*) design utilized a splash plate within the thrust chamber on which liquid-propellant streams played. Good mixing is obtained in this design but hot spots may occur on the splash plate. Premix injectors have been tried wherein mixing is accomplished just prior to injection into the thrust chamber. Since rocket propellants by their nature are high-energy substances, this type of design is subject to explosion. Swirl-type sprays are another approach to injection configuration. Shop producibility, critical tolerances and cost enter into injector head considerations and some compromises in performances are usually accepted.

Often related to injector head dynamics is the phenomenon of oscillatory combustion instability in the combustion chamber. Often exhibiting audible effects of chugging and screaming, these high-speed pressure differentials can destroy a rocket motor in a few seconds. Because the mixture ratios of different propellants vary widely, a rocket motor is tailored for specific propellants and it is not generally possible to operate an engine efficiently on different propellants than those for which it was designed.

Valves for rocket engines offer design problems from the nature of the propellants and requirements of high reliability and precise operation. Many rocket flights have aborted because of sticking valves. Valves are usually operated by electric solenoids or are pneumatically and/or hydraulically actuated.

Design of tankage for propellants has evolved in recent years to integral systems wherein the thin wall of the tank is the skin of the rocket vehicle itself. In addition to the weight of the propellant, rocket tankage must withstand some gas pressure head for turbopump systems and several hundred pounds pressure for gas-pressurized propellant supply systems.

4. Propellant Supply Systems.—The simplest method of forcing liquid propellants into the combustion chamber is by gas pressure. An inert gas is used, such as helium or nitrogen. Because the combustion chamber pressure is usually 300 lb. or more, the pressurizing gas must be higher to overcome frictional losses in propellant lines, valves, thrust chamber cooling jacket and injector head. This high pressure necessitates heavy tanks, affecting adversely the mass ratio of the vehicle. Gas pressurization is a simple and reliable system, however. It was used successfully in the U.S. X-1 supersonic research airplane. In this case liquid nitrogen was converted in a heat exchanger to high-pressure gas. For small vehicles helium gas at several thousand pounds pressure may be used, with operating pressure being reduced through a regulating valve. Another source of pressurizing gas is the reaction of small quantities of the propellants themselves in a specially designed gas generator or even within the propellant tanks. In turbopump systems a source of high-velocity gas drives a turbine wheel which, in turn, drives centrifugal pumps between the propellant tanks and the rocket motor. High-strength hydrogen peroxide (95%–98%) is commonly decomposed by a catalyst bed within a gas generator. The decomposition products, oxygen and steam, are led through a nozzle and impinge on the turbine blades.

The propellant pumps are usually centrifugal. They may be located on opposite ends of the turbine shaft or, in cases of large pumps, driven by a gear train. A certain pressure head is necessary to prevent cavitation. This is supplied from a lightweight high-pressure storage bottle through a pressure regulator to the propellant tanks. Other turbopump-drive systems utilize a high-pressure stored gas start cycle and then bleed a portion of one of the pumped propellants to an expansion jet to drive the turbine. This turbine gas exhaust may then be burned in the combustion chamber, utilizing its thermochemical heat content.

Because of the sloshing or floating action of propellants within tanks of a maneuvering vehicle or during restart under conditions of weightlessness, "bladders," or flexible tank liners, may be used as positive expulsion devices to control the discharge of propellants from the tanks. Another technique is the use of small rockets to impart a small acceleration to the next stage at burnout. This force causes the weightless propellants to move to the end of the tank, thus making them available for ignition of the stage rocket engine. These small rockets are known as ullage rockets.

5. Ignition.—Liquid-propellant combinations which ignite spontaneously are called hypergolic. Because ignition rates may be low when propellants such as acid and aniline are sprayed into a cold thrust chamber, a slug of another more highly reactive propellant may be injected initially. If ignition does not take place rapidly, the accumulation of unburned propellants may build up quickly to a point where chamber pressure limitations are exceeded when combustion does occur, resulting in an explosion. In the case of nonhypergolic propellants, such as liquid oxygen and gasoline, a source of flame, hot wire, spark or pyrotechnic (squib) igniter must be provided. The V-2 used a swastika-shaped, pyrotechnic pin wheel mounted on a light frame within the combustion

chamber.

6. Ground Testing.—Many tests are required in the development of a rocket-motor design. The term static test is used to describe rocket-motor operations wherein the motor is bolted to a test stand and fired. Static test stands provide for measurements of thrust, propellant flows and a variety of significant temperatures and pressures. Control is maintained from within a reinforced-concrete bunker or blockhouse. The rocket firing is viewed by means of mirrors or periscopes or at a distance through bullet-proof glass. Closed-circuit television may also be used in the case of large motors. In liquid-motor development, so-called battleship (heavyweight)-propellant tankage is employed and gas pressure often used to force the propellants into the thrust chamber. In initial chamber-design tests water cooling provides a large safety factor over regenerative cooling. Flow measurement tests of injector heads and gas generator and turbine pump development usually proceed separately. Eventually all components are combined for system tests. When missiles are in final stages of development the entire vehicle is mounted in other test stands and fired. These are known as captive tests. The cost of rocket test facilities, with associated plumbing, tankage, propellant storage and necessary safety provisions of reinforced concrete and large safety distances, is naturally great.

Scaling of successful rocket-motor designs is not simple. The requirements for very large thrust engines for space-flight operations can be met in two ways—manifolding (or clustering) a number of existing engines or designing one new and larger engine. The first technique is simpler. In the United States, the requirement for a rocket engine of more than 1,000,000-lb. thrust was approached by both methods. In the one case, eight 150,000-lb. thrust engines were specified to be clustered and at the same time a single-barrel engine of 1,000,000-lb. thrust was ordered. The time for completion of the second approach was estimated to be three to four times as long but held promise of eventual higher mass ratio advantages.

7. Nuclear Rockets.—The development of reliable nuclear fission reactors has led to the possibility of utilizing nuclear energy as a source of power for rockets. In this case the energy does not derive from the heat of combustion of a chemical reaction but from fission of nuclear particles. Although the amount of energy potentially available is very much greater, the conversion to kinetic energy in a rocket exhaust jet is more complicated. Two nuclear rocket systems were under study and development in the United States in the mid-1960s. One was the rather audacious notion, suggested shortly after World War II, of obtaining impulse by a series of small nuclear explosions. In theory, these explosions behind a sturdy structure would propel it upward. The more conventional approach to a nuclear rocket is to use the heat of a fission reactor to heat a working fluid and expel the hot gas through a nozzle. Since the nuclear products are in a closed cycle, no radioactive particles are in the exhaust. The most obvious working fluid is low-molecular-weight hydrogen. The working fluid or propellant in this system would not be burned but simply heated and ejected. Some of the major problems associated with the design of a nuclear reactor are related to the design of an efficient heat exchange to transfer heat energy from the reactor to the propellant, cooling the thrust chamber walls, shutdown and restart, and nuclear radiation. The range of specific impulse (*i.e.*, pounds thrust per pound per second of propellant flow) achievable with nuclear rockets is estimated in the order of 700–1,000 sec. Chemical propellants have a limitation of about 430 sec. at sea level.

8. Electrical-Propulsion Systems.—Whereas chemical-propellant rockets are characterized by high thrust for short durations, a number of electrical systems have been proposed which would yield a low thrust over a long period of time. Specific impulses of such systems range from about 1,000 to 10,000 sec. and more. Several approaches to electrical thrust systems are under development. All such systems, because of low thrust, must be carried to the altitude of a low Earth-satellite orbit. From this orbit these devices will operate in pulsed fashion or continuously for weeks, months or even years in the case of distant interplanetary flight. Electric power to operate these thrust devices would be obtained from direct conversion of solar energy (solar batteries) or from nuclear electrical generators, as in a plasma thermocouple. It can be shown that specific impulses of 1,500 to 5,000 sec. are optimum for space missions from low-altitude Earth-satellite orbit to lunar orbits. In unmanned space journeys, such as placement of communications satellites in the 24-hour, stationary orbit (22,300 mi.), additional flight time (of extra days) is not necessarily important. The advantages of using electrical propulsion of 1,500 to 5,000 sec. are, however, truly significant. Earth take-off weights may be reduced as much as one-half from the weight needed to accomplish the same mission using chemical rocket propulsion throughout. In the particular case of a communications satellite payload, which could utilize the electrical power supply of the propulsion system, earth take-off weight might be reduced to one-third.

Among the electrical thrust devices under development is the electrothermal arc jet. This device utilizes an electric arc to heat the propellant, or working fluid, which is expelled through a rocket nozzle to the rear. Another device under development accelerates the plasma, produced by the electric arc, by means of a magnetic field. Still other electric thrust devices operate in a pulsed fashion and utilize magnetohydrodynamics (MHD) to accelerate high-temperature gases, as in the MHD shock tube.

Best known of the electrical thrust devices is the ion rocket. In this system electrostatic fields rather than electromagnetic fields are used to accelerate dust particles or positively charged ions such as metallic cesium. Specific impulse ranges of this device are estimated at 5,000 to 100,000 sec. Of even higher specific impulse is the photon rocket—wholly theoretical—wherein energy is converted to light and expelled as such. The photon rocket system, conceived and elaborated by Eugen Sänger, is not feasible to construct with currently available materials and techniques because of the extremely high temperatures required.

9. Other Systems.—One final low-thrust device for space propulsion is the so-called hydrogen heater, in which solar energy is concentrated by hemispherical reflectors onto a heat exchanger, which in turn heats hydrogen to a high temperature; the hydrogen is then accelerated through a rocket nozzle to the rear. Although the above low-thrust propulsion programs for space missions appear exotic compared to conventional rocket systems, the inherent advantages of these high-specific-impulse propulsion devices make their development desirable for interplanetary exploration.

VI. ROCKET PROPELLANTS

Rocket propellants, by the chemical process of combustion, provide the hot gases which produce reaction force (thrust) when ejected to the rear. These chemical propellants are divided classically into solid and liquid categories. Some development has been conducted on solid-liquid (hybrid) systems in which one of the propellants is liquid and injected into a solid-propellant combustion chamber. Hybrid motors of 15,000-lb. thrust and many minutes of burning time have been fired in the U.S.

In many space flight propulsion systems such as the nuclear rocket, plasma jet or hydrogen heaters, the propellant is not a combustible but serves as a working fluid, its purpose being to transform heat and other forms of energy into kinetic energy.

1. Solid Propellants.—Various formulations of black powder (gunpowder) were the only source of propellant for rockets until late in the 19th century when nitroglycerin was discovered. Saltpetre was the oxidizer in this mixture, while the sulfur and charcoal served as fuel. This exothermic reaction may be written approximately

$$2KNO_3 + S + 3C \rightarrow K_2S + 3CO_2 + N_2$$
$$+ 550 \text{ cal. per gram of mixture reacting}$$

In a rocket motor black powder yields a specific impulse (I_{sp}) of 50–70 sec., depending upon chamber pressure and formulation (typical, by weight: 75% KNO_3; 15% C and 10% S). The flame temperature of gunpowder is about 1,500°–3,000° F. (815°–1,650° C.) and the mixture burns smoothly even below combustion chamber pressures of 100 p.s.i. The volume of gas produced is about 400 times the original volume of the charge.

By shifting from potassium to sodium nitrate, 60 cal. per gram

more heat is generated. Moreover, since the average molecular weight of the combustion products is reduced slightly, the exhaust jet velocity is increased.

With the advent of nitro explosives new possibilities opened up for obtaining high-temperature gases smoothly and reproducibly. Motor design changes were required to accommodate the higher combustion temperatures and pressures. Rocket propellants based upon nitrocellulose (guncotton) are known as single-base propellants. Mixtures of nitrocellulose and nitroglycerin are known as double-base propellants. These double-base mixtures are similar to smokeless powders for firearms. To improve the physical and chemical properties of double-base propellants, small amounts of additives are usually present as stabilizers. These additives prevent decomposition in storage or improve combustion characteristics and bond the propellant to the motor casing.

Double-base propellants require a minimum operating-chamber pressure of about 500 p.s.i. for smooth burning. Lower pressure results in irregular burning and oscillatory combustion. Flame temperature is in the order of 5,000° F. (2,760° C.). Heat yield is in the order of 850–1,200 cal. per gram. Specific impulse is about 180–210 sec. The volume of gases produced from double-base propellants is about 1,500 times initial propellant volume.

Solid propellants are divided into two main classes: homogeneous and composite. The term homogeneous is applied to solid-propellant mixtures in which the propellant or mixture of propellants are intimately associated in a colloidal state. Single- and double-base propellants are examples of homogeneous propellants. In composite (or heterogeneous) propellants, the substances, although finely ground, are in distinctly separate phases. An example of composite propellant is gunpowder.

Nitrocellulose or nitroglycerin is different from gunpowder with respect to the process of chemical combustion. The molecules of saltpetre (KNO_3), sulfur (S) and carbon (C) in gunpowder must be intimately mixed in order to react. Nitrocellulose contains within each molecule sufficient fuel and oxidizer for complete reaction without the addition of other substances. In this regard, nitrocellulose may be considered a monopropellant.

In World War II both single- and double-base propellants were used extensively. In an important German double-base mixture, WASAG R-61, diethylene glycol dinitrate was substituted for nitroglycerin.

In the U.S., a number of new important composite propellants were produced. One of these was the GALCIT series which was a mixture of 75% potassium perchlorate and 25% asphalt oil. Another variety was the NDRC mixtures. A typical example of these was about 46% each of ammonium picrate and sodium nitrate mixed with 8% plastic resin binder. Other composite mixtures used ammonium nitrate as oxidizer and still others utilized synthetic rubber as fuel. An important advantage of composite propellants was their ability to be cast directly in the case.

Generally speaking, a solid rocket propellant may be formulated and designed to wide performance specifications, with individual motors operating from a fraction of a second to 30 sec. or more burning time. Rocket motors 10 ft. in diameter, containing more than 100,000 lb. of propellant and developing 1,000,000 lb. of thrust, have been made and fired. Total impulse, *i.e.*, thrust (lb.) × time (sec.), of many million pound-seconds has been achieved in the U.S. Solid-propellant rocket systems are generally lower in performance than liquid systems but offer advantages in readiness of operation and ruggedness desired for field operations.

Programs for solid-propellant motors from 156 to 260 in. in diameter are under development in the U.S. Such motors are expected to deliver as much as 3,000,000 lb. of thrust.

Classic problems in solid-propellant production include variation in performance with temperature, development of cracks or shrinkage in storage or transit and sensitivity to moisture. Most propellants tend to have higher burning rates in warm climates. Rocket stores may vary in military field operations from −70° F. to 150° F. (−56.6° to 65.6° C.). Cracks, fissures or shrinkage increase the burning surface area so that pressure build-up on firing may reach disastrous proportions. X-ray inspections are a common specification of rocket grain manufacture. Some formulations are hygroscopic and must be stored in dry atmosphere or moisture will be absorbed and performance reduced. A new technology of rocket propellant surveillance has developed which deals with the practice and procedures of storage and periodic inspection of rocket matériel. Procedures are evolved during development of rockets so that safe and adequate provisions may be put into effect when production programs are under way. Rocket propellants are inherently high-energy, unstable substances, intimately mixed. Physical-chemical processes such as deterioration, degradation and autoignition are important, along with variations in shape, size and density resulting from temperature and humidity effects and stress relief processes resulting from aging.

2. Liquid Propellants.—Generally speaking, liquid propellants have higher specific impulse than solid propellants and are more versatile, since throttling and restart are possible. Another important advantage is that liquid engines can be checked out, fired and calibrated precisely before launch. But liquid-rocket systems are more complex and tend to be less rugged and reliable.

Rocket systems using liquid propellants fall into two general classes: monopropellant and the more common bipropellant. Monopropellants are substances which decompose when heated or upon contact with a catalyst and give off large quantities of heat. An example is 90% hydrogen peroxide, which decomposes into water (steam) and oxygen. By mixing hydrogen peroxide with a fuel such as an alcohol, a combustion reaction also takes place, yielding more heat. Other monopropellants are nitromethane, ethylene oxide, hydrazine and propyl nitrate. Monopropellant systems are simpler but are lower in performance than bipropellant systems. Specific impulses of the above monopropellants range from 160–220 sec.

Tsiolkovski, Goddard and Oberth all independently recognized and wrote of the advantages of liquid bipropellants. In these systems one propellant is the oxidizer and the other the fuel. Common oxidizers are liquid oxygen, hydrogen peroxide, fuming nitric acid and nitrogen tetroxide. The fuels used most often have been ethyl alcohol (75% + 25% water), kerosene or gasoline, hydrazine derivatives, aniline, furfuryl alcohol and liquid hydrogen.

Although experiments have been performed on literally thousands of fuels and a lesser number of oxidizers, no completely ideal propellants have emerged. Each propellant has some minor or major disadvantages that must be weighed against the particular design application and mission. For example, the problems of corrosivity and toxicity of fluorine or the low density of hydrogen may be accepted to obtain the high performance of these propellants in space applications. Or, the lower specific impulse of solid propellants may be accepted to obtain the advantages of readiness in antimissile defense systems.

In evaluation of liquid propellants the following properties are of engineering importance to the rocket designer: heat of reaction, average molecular weight of combustion products, stability (*e.g.*, to heat, shock), speed of reaction, ignition characteristics, density, viscosity, vapour pressure, specific heat and corrosivity. For regenerative cooling—and all large, long-burning engines are so cooled—at least one of the propellants must have sufficient stability, specific heat capacity, thermal conductivity and high saturation temperature to serve as a coolant. Despite its low temperature −297° F. (−183° C.), for example, liquid oxygen is unsatisfactory as a regenerative coolant. In the case of the V-2, the ethyl-alcohol fuel was diluted to 75% with water to improve its cooling ability.

Quite apart from properties affecting rocket power plant design are the logistic and handling qualities of liquid propellants. For bulk storage and transfer of propellants, corrosivity, stability and vapour pressure are important as well as freezing point and inflammability. Toxicity is important to personnel. Cost and bulk availability are also important considerations to program planners.

By the mid-1960s achievable specific impulses of rocket motors in operational missiles had climbed to about 280 sec. In the U.S., development programs for storable oxidizers such as nitrogen tetroxide and chlorine trifluoride were under way as well as major programs for liquid hydrogen, liquid fluorine, boron hydrides, oxy-

gen difluoride and liquid fluorine-oxygen mixtures. Fruition of these propellant programs and development of rocket motors with higher operating pressures will result in sea level specific impulses of 370 sec. or better—near the maximum for chemical-combustion rockets. In the realm of exotic propellants, considerable research effort has been applied to the study of free radicals in the hope of stabilizing these energetic metastable substances. Also, the use of liquid ozone and metal additives has been studied. *See* also PROPELLANTS.

VII. MISCELLANEOUS APPLICATIONS OF ROCKET POWER

In addition to the primary uses of rocket power—for missile propulsion, fireworks and for upper-atmosphere research and space exploration—rocket systems have been used for a wide variety of other purposes.

1. Aircraft Propulsion.—Rocket engines have been used as the prime power plant for high-speed aircraft as well as for auxiliary propulsion. Two versions of a rocket-powered airplane, the Messerschmitt Me-163B and Me-163C, appeared too late in World War II to be important militarily. But their flight speeds, 560–590 m.p.h., would have made them extremely effective against long-range bomber formations. The Austrian Eugen Sänger and his brilliant co-worker Irene Bredt (later Mrs. Sänger) headed the air force rocket test station at Trauen. It was there that the experimental work was conducted which laid the basis for the significant report, *A Rocket Drive for Long Range Rocket Bombers* by Sänger and Bredt, published by Robert Cornog (1952).

An interesting intermediate step between the guided missile and the piloted interceptor was the rocket-powered Natter, designed by Erich Bachem. This vehicle, carrying a pilot, was designed to be launched vertically toward attacking bomber formations. The Natter was designed to have a maximum horizontal flight speed of 620 m.p.h.

The concept of a rocket-powered airplane for high-speed research studies originated in the U.S. at the time the Germans were developing their Me-163 rocket-powered interceptor. After the war this work continued under air force sponsorship in co-operation with the National Advisory Committee for Aeronautics (NACA). The 6,000-lb. liquid oxygen-alcohol rocket engine was a navy bureau of aeronautics development. This engine consisted of four 1,500-lb.-thrust combustion chambers which could be fired independently or in combination.

Initial flights of the X-1 airplane were made in 1946. Because of the rapid rate of burning of the rocket propellants—almost one ton per minute, with all four motors—powered flight lasted only a few minutes. All landings were without power, gliding down to the desert floor at Edwards air force base, Calif. For the same reason, the X-1 was carried aloft and launched from a specially modified B-29 bomber. Supersonic speed was achieved for the first time in 1947. In 1948 a new altitude record was set at 70,140 ft.

Another version of this airplane, the X-1A, used a turbopump propellant supply system instead of the heavier, nitrogen pressure feed method. The X-1A reached a speed of 1,650 m.p.h. at 90,000 ft. in 1953. Meanwhile the navy in co-operation with NACA had developed another rocket research airplane. Known as the D-558 this airplane, which also carried a turbojet engine, was first to fly at Mach 2 (twice the speed of sound).

The X-2 was a rocket-powered research aircraft designed for even higher speeds. The rocket engine developed 15,000-lb. thrust—twice as much as the X-1. Mach 3.3 (2,200 m.p.h.) and 126,000 ft. altitude records were made in the X-2.

In 1958 another rocket research airplane, the X-15, was revealed to the public. The X-15 was powered by a rocket engine developing 50,000-lb. thrust and was designed to be launched above 40,000 ft. from a B-52 bomber. An altitude of 353,000 ft. and speeds greater than 4,100 m.p.h. have been achieved.

In France, the Trident fighter was powered by two 6,615-lb.-thrust rocket engines. Other fighter and interceptor aircraft (Durandal and Mirage III-A) carried liquid-propellant engines for burst speed in addition to turbojet power plants. In Great Britain an 8,000-lb.-thrust hydrogen peroxide-kerosene engine was developed which could be throttled over a wide range of thrust.

2. Jet-Assisted Takeoff.—During World War II both the U.S. and Germany developed jet-assisted-takeoff (jato) units for aircraft. Both solid and liquid propellants were used to enable land and seaplanes to take off with a shorter run or with increased loads, or both. Development of this technology continued after the war, particularly in the U.S. where the units were produced for the commercial as well as for the military market. Jato units are sometimes designed as a fixed installation in aircraft, but otherwise are intended for parachute drop after takeoff.

3. Other Applications.—Rockets are used in the U.S. to propel supersonic sleds along a twin-rail track. These sleds serve as test beds for acceleration tests of various components such as parachutes, aircraft ejection seats and nose cones. Important aeromedical tests on men have also been performed with rocket sleds. Accelerations as high as 100 gravity (g), decelerations of 150 g and velocities up to 4,600 ft. per second are possible. Both liquid- and solid-propellant rockets are used. Braking is accomplished by a parachute or, more often, by extending a scoop beneath the sled into a trough of water between the track rails.

Buried land mines were attacked in World War II by rocket-propelled devices. One of these devices, known as the Snake, pulled a 100-ft. train of skis, linked together and carrying TNT. Another version was a U-shaped motor which dragged primacord explosive to detonate the mine field.

A unique device based upon a German development was the Wedge. This item used a powerful rocket to drive a 1-in. rod, 6 ft. long into the ground. By pulling out the rod, inserting a length of primacord and detonating, a hole of 10–12 in. in diameter was created. Various other wartime rocket-propelled material included smoke bombs which in barrage-firing could swiftly erect a smoke screen. Antiradar rockets, used in the Allied invasion of Normandy, released metal foil strips, known as window, at peak of trajectory. These foil strips caused spurious radar reflections and appeared as swarms of aircraft on radar screens. Grapnels, even rope ladders, have been boosted over heights by rocket in commando-type operations. Recoilless rifles and mortar-fired rockets have been developed.

Solid rocket propellants have been used for turbojet engine starters, to furnish gas pressure to power small gyroscopes or electric turbogenerators for guided missiles, and to pressurize flame throwers. Firing solid-propellant charges in specially designed tools in oil wells creates high pressures which fracture the earth and increase oil production. Rocket jets have been used to drill holes through earth and rock. Rocket motors provide a high-temperature jet which is useful for materials tests as in the case of ballistic missile nose-cone development.

In the U.S. X-15 research airplane, the rocket motor is designed to accelerate the vehicle to 100 mi. altitude. In the outer reaches of the atmosphere the craft's wings and tail surfaces would be useless to orient the airplane correctly for re-entry flight on the downward side of the ballistic trajectory. Accordingly, rocket jet nozzles on the wings and fuselage are designed to rotate and correctly orient the X-15 under these conditions.

The possibility of delivering a number of men and equipment accurately and at long ranges with IRBM and ICBM vehicles has been proposed. Even rocket boost of individual soldiers for hundreds of yards has been achieved by the use of a device known as a "rocketbelt."

Rockets have been attached to automobiles, boats, gliders, iceboats, motorcycles, rail cars and even a man on skates. These experiments, which occurred mostly in the 1920s and 1930s, were more ingenious than efficient, more publicity-seeking than sound.

VIII. ROCKETS AND SPACE FLIGHT

Man's dream of traveling through space to the moon and the planets is an old one—as old as astronomy itself. Centuries before the Christian era the courses of planets and stars were plotted but there was no appreciation then of the distance to these "abodes of the gods"; no understanding of the lack of atmosphere a short distance from the Earth's surface; nor even that the world was round. However, once man had learned that the moon and

planets were actual bodies, a long way off, he had an urge to visit them. Willy Ley (see *Bibliography*) traces the story of man's interest in space flight from its earliest beginnings; 17th-century authors related fantasies in which man was drawn by "wild swans" or carried aloft "on the dew" to visit the moon. As the telescope developed and Newton's laws became applied, the physical problems of space journeys became more apparent. Jules Verne's famous *De la terre à la lune* ("From the Earth to the Moon") was published in 1865. Verne shot a space ship with passengers on a flight around the moon appreciating correctly many aspects of the voyage such as weightlessness in free fall.

By 1900 the recognition of rocket propulsion as the key to space flight began to spread. Scientists such as Tsiolkovski, Goddard and Oberth wrote serious technical treatises on the potentialities of rocket-powered flight. Rocket and space flight societies focused public attention on their experimental efforts. Their dreams were great but financial support was limited and successes were few. And each society had its share of crackpots. The aim of these societies was interplanetary flight rather than improved war rockets, but the latter were to appear first, in World War II.

The German heritage of the V-2 to the postwar world made it abundantly clear that with only a small extrapolation, payloads could be accelerated to satellite velocity. The development of the ICBM by the U.S. and U.S.S.R. furnished the additional power necessary to orbit significant payloads and to probe the solar system.

Whenever a new scientific frontier has been penetrated the eventual results have been of economic benefit to mankind. It can only be hoped that in moving into this new dimension man will also learn better the art of living with his neighbours, and that the rocket, developed as a machine of war, will become a tool for peaceful research and understanding.

ROCKFORD, a city of Illinois, U.S., the seat of Winnebago County, is located on the Rock River in the midst of an important industrial, agricultural, and commercial area in the north-central part of the state, 17 mi. S of the Wisconsin line and 90 mi. NW of Chicago. Founded by New Englanders in 1834, it was named for the rock-bottomed ford, the site of a stagecoach stop on the trip between Chicago and Galena. It was incorporated as a village in 1839 and as a city in 1852. Supplied with waterpower by a dam constructed in 1844, the town grew rapidly; in 1960 the population of the city was 126,706 and that of the standard metropolitan statistical area (Winnebago County) was 230,091. (For comparative population figures *see* table in ILLINOIS: *Population.*)

Rockford is a manufacturing city, its products including machine tools, hardware, furniture, farm implements, household appliances, leather goods, and paint. Camp Grant, a reception and medical-replacement centre during World Wars I and II, has been converted into the greater Rockford Airport.

Rockford College, a private institution founded in 1847 as Rockford Female Seminary, became coeducational in 1959. In 1958 the college acquired land on the east edge of the city for a new campus, the development of which was expected to extend over a 15-year period. Rockford is a city of many churches, including a Roman Catholic procathedral. The town has a symphony orchestra, an art gallery, and a little theatre, and also has many well-equipped playgrounds and parks. (H. E. B.)

ROCKHAMPTON, a city and port on the east coast of Queensland, Austr., situated on both banks of the Fitzroy River at the head of ocean navigation 35–40 mi. (56–64 km.) from the sea. Pop. (1961) 44,128. Rockhampton, which was proclaimed a municipality in 1860, is well designed, with wide streets, many substantial buildings (including an Anglican and a Roman Catholic cathedral), and fine public parks and gardens. The city is the base of a railway system which connects such widely separated places as Longreach, Winton, Blair Athol, Callide coalfields, and Springsure, and which is being continually extended. Along the coast the Great Northern line links Rockhampton with Brisbane and other coastal towns, with various seaside resorts (Yeppoon and Emu Park), and with the ports of Port Alma and Gladstone, which have harbours for ocean vessels. Railway repairing and other industries are carried on in the city, and nearby are two large meat-preserving and freezing works, one of which is the largest in the southern hemisphere.

Mount Morgan, 24 mi. (39 km.) SSW, which in the 1880s became one of the richest gold mines in Australia, contributed greatly to the city's growth. The Fitzroy River and its tributaries, including the Dawson and Mackenzie, drain a basin of 58,000 sq.mi. of great diversity and economic value. The hinterland of Rockhampton thus contains extensive pastoral country extending as far west as Longreach, considerable mineral resources including coalfields (*e.g.*, Blair Athol mines and Moura coalfields), and rich agricultural and dairying lands—in particular the Dawson River irrigation area (total projected size: 170,000 ac.). The Dawson River Valley is the centre of the cotton region in Australia, which yields 75% of total production and also has 80,000 ac. of wheat which yield about 1,500,000 bu. annually. Around Rockhampton itself is fertile agricultural land noted for its tropical fruits, maize (corn), and dairy products. The climate is hot and humid but not unhealthful, with average annual temperatures from 17° to 28° C (62° to 82° F) and an annual average rainfall of 40 in. (1,000 mm.) falling within about six weeks during the summer.

ROCK HILL, a city of York County, S.C., U.S., 27 mi. S of Charlotte, N.C. Having become the site of a U.S. post office in 1852, it was incorporated as a village in 1870 and as a city in 1892. Major industries include textiles and paper manufacturing. Located in Rock Hill are Winthrop College (state college for women; founded 1886), the Glencairn (azalea) Garden, a children's nature museum, and the York County Hospital. The city has a council-manager form of government, in effect since 1915. For comparative population figures *see* table in SOUTH CAROLINA: *Population.* (J. H. Wo.)

ROCKINGHAM, CHARLES WATSON-WENTWORTH, 2ND MARQUESS OF (1730–1782), British statesman, prime minister from July 1765 to July 1766 and from March to July 1782 and leader of the parliamentary group known as the Rockingham Whigs, was born on May 13, 1730. He was the fifth and only surviving son of Thomas Watson-Wentworth (d. 1750),

who was created marquess of Rockingham in 1746. In 1745 he ran away to serve as a volunteer under the duke of Cumberland against the Jacobite rebels. In September 1750 he was created Baron Malton and Earl Malton in the Irish peerage. Three months later he succeeded to his father's rich estates in Yorkshire, Northamptonshire, and Ireland. In 1751 he became lord of the bedchamber to George II and was appointed to judicial and military offices in Yorkshire. In 1762, after the dismissal of his friend William Cavendish, 4th duke of Devonshire, from his office of lord chamberlain, Rockingham resigned from the bedchamber in sympathy.

In July 1765 George III, failing to get the services of William Pitt, turned to Rockingham to form a ministry to replace that of George Grenville, which the king hated. From the start his cabinet was weakened by internal dissensions and Pitt refused to support it in the House of Commons. Its policy of conciliating the American colonists by repealing the Stamp Act of 1765 was wise but unpopular and parliamentary support was only obtained by coupling repeal with a Declaratory Act reaffirming Parliament's powers to pass laws for the colonies "in all cases whatsoever." In July 1766 the government collapsed and was replaced by the ministry of Pitt, who became earl of Chatham. From 1766 until 1782 Rockingham was leader of a strong parliamentary opposition, which was at times opportunist and factious, but which found a genuine cause of principle in its opposition to the war against the American colonists. From March 1782 until his death he headed a ministry which began negotiations for peace to end the American war, and legislated a program of "economical reform," mainly inspired by Edmund Burke (*q.v.*). He also gave legislative independence to the Irish Parliament by repealing the Declaratory Act (1719) and drastically amending Poynings' Law. Rockingham died on July 1, 1782, and was buried at York Minster. Many of his letters are contained in *The Correspondence of Edmund Burke,* volume ii, edited by L. S. Sutherland (1960); volume iii, edited by G. H. Guttridge (1961); volume iv, edited by J. A. Woods (1963).

BIBLIOGRAPHY.—G. H. Guttridge, *English Whiggism and the American Revolution* (1942), *The Early Career of Lord Rockingham, 1730–65* (1952); J. Brooke, *The Chatham Administration, 1766–1768* (1956); I. R. Christie, *The End of North's Ministry, 1780–1782* (1958).

(I. R. C.)

ROCK ISLAND, a city and the seat of Rock Island County, western Illinois, U.S., lies along the Mississippi River near the mouth of the Rock River and opposite the large federal island which gave the settlement its name. With Moline, East Moline, and Davenport, Iowa, it forms a complex known as the "Quad Cities." Settlers were attracted by the presence of Ft. Armstrong on the island and by the cornfields of the Fox Indians. Ft. Armstrong (now a federal arsenal) was headquarters of operations in the Black Hawk War. As settlers moved in, Rock Island (originally called Stephenson) became a transportation hub and was first incorporated in 1841. In 1854 the town was reached by the Rock Island Railroad, whose promotors built the first bridge across the Mississippi. Industry is diversified, including railroad shops and the manufacturing of footwear and farm equipment. Swedish immigrants established Augustana College and Theological Seminary in 1860. The college library contains material rich in Swedish Americana. Pop. (1960) 51,863; Davenport-Rock Island-Moline standard metropolitan statistical area (*see* DAVENPORT), 319,375. For comparative population figures *see* table in ILLINOIS: *Population.*

(D. L. A.)

ROCKNE, KNUTE KENNETH (1888–1931), U.S. football coach whose colourful personality and style of play captured the public's imagination during the "golden era" of sports in the 1920s, was born in Voss, Nor., on March 4, 1888. In 1893 his family migrated to the United States and in 1910 Rockne entered the University of Notre Dame, Notre Dame, Ind. There he became a track and football star (1911–13), assistant football coach (1914), and head coach (1918–31). Recognized as one of the game's greatest coaches, Rockne's popularity and that of his teams stemmed in large part from the loyalty of thousands of persons who had never attended college, the so-called "subway alumni," who adopted his teams as their own. In compiling his record of 105 victories, 12 defeats, and 5 ties (including five undefeated seasons), Rockne perfected such maneuvers as the "Notre Dame shift"; taught such famous players as George Gipp and the 1924 Notre Dame backfield known as the "Four Horsemen"; and was the first to substitute entire teams (which he called "shock troops") during a game, a forerunner of modern platooning. He was killed in a plane crash in Kansas on March 31, 1931. *See* also FOOTBALL: *U.S. College Football History.*

(J. D. McC.; X.)

ROCK RIVER, a nonnavigable river in the north central U.S., rises in Washington County in eastern Wisconsin and flows in a generally southwesterly direction to join the Mississippi River at Rock Island, Ill. Its 300-mi. length is shared about equally by the two states and from source to mouth it drops about 500 ft. Ten small dams on the river have a total power generating capacity of 12,545 kw. The river drains an area of 10,879 sq.mi., most of which is good agricultural land. The bottomlands along the lower course are frequently subjected to extensive flooding in the spring and require levee protection. Major cities along the river include Watertown, Janesville, and Beloit, Wis., and Rockford, Dixon, Sterling, and Rock Island, Ill. Its principal tributaries are the Pecatonica, Kishwaukee, and Green rivers. Near Oregon, Ill., in Lowden Memorial State Park, Lorado Taft's heroic 48-ft. statue of "Black Hawk" rises majestically above the wooded slopes of the valley.

(E. HG.)

ROCKVILLE CENTRE, a village of Nassau County on Long Island in the southeastern part of New York State, U.S., about 20 mi. E of New York City. The area was first settled in the 17th century when a few families built several log huts. In 1853 the settlement, which was mainly a farming community, was named Rockville Centre after the Rev. Mordecai ("Rock") Smith.

The village, which was incorporated in 1893, became one of the residential suburbs on Long Island with a large portion of its population commuting to New York City for employment. For comparative population figures *see* table in NEW YORK: *Population.*

(D. L. D.)

ROCKY MOUNT, a city of North Carolina, U.S., in Nash and Edgecombe counties, 54 mi. E of Raleigh on the Tar River. Incorporated in 1867, it grew up around the state's second cotton mill, built in 1818 on the river. Its name derives from unusual outcroppings of rock at this coastal plains site. There in 1836 P. T. Barnum made the first recorded stop with his own circus troupe. It was chartered as a city in 1907 and in 1927 the city manager-council form of government was adopted.

Rocky Mount is one of the largest bright-leaf tobacco markets in the world. Its varied industry includes cotton mills, railroad shops, and plants producing fertilizer, lumber, bricks, steel tanks, and cottonseed oil. For comparative population figures *see* table in NORTH CAROLINA: *Population.*

(W. S. P.)

ROCKY MOUNTAIN NATIONAL PARK, in north central Colorado, U.S., 410 sq.mi. (1,062 sq.km.) in area, was established in 1915 to preserve an outstanding section of the front range of the Rocky mountains. Located about 64 mi. N.W. of Denver, the region is famous for its high mountain peaks, broad valleys, rugged gorges, flowered meadows, alpine lakes and plunging streams, and also for its abundant wildlife, with such animals as the Rocky mountain bighorn sheep, mule deer, American wapiti, mountain lion, beaver and many species of birds inhabiting the area. A remarkable variety of plant life can be seen within the park, with more than 700 species of plants known to be present. The tundra of the high country in the park is a unique island of arctic vegetation, surrounded on all sides by plant communities of lower latitudes. Within the park are more than 100 named peaks which are over 10,000 ft. in elevation. Longs peak (14,255 ft.; 4,345 m.) is the highest summit in northern Colorado, and one of the world's most popular climbs. The pastoral landscapes of the meadows and the rolling moraines are the result of glacial deposition. About 300 mi. of trails permit hiking, and the national park service provides guided field trips and informal nature walks. Trail Ridge road traverses the park, with about 11 mi. of the highway being above the 11,000-ft. timber line. Except for 12 mi. between Estes park and Hidden valley kept open for winter sports enthusiasts, this road is closed by snow to transmountain travel

from about Oct. 15 to May 30. Slopes and ski runs are available for skiing during the winter months.

ROCKY MOUNTAINS, the principal division of that vast system of highlands occupying part of the western United States, northern Mexico, western Canada and extending into northern Alaska. Standing between the great continental plains on the east and the region of elevated basins, ranges and plateaus extending from central Mexico through Nevada to northern British Columbia on the west, they constitute the backbone of the continent, as well as a major topographical feature of the entire globe. The Rocky mountain system does not include any of the Pacific border mountain system of North America (the Alaska range, Coast range, Cascade range, Sierra Nevada, Sierra Madre Occidental), from which it is separated by the basin, range and plateau province of Mexico, Nevada and British Columbia.

At the south the Rockies begin in the Sierra Madre Oriental, north of Oaxaca, Mex. North of Monterrey, Mex., the Sierra Madre Oriental is submerged in a rugged plateau region through which the Rio Grande has cut a narrow gorge at the Big Bend. North of the Mexican border, in west Texas and southern New Mexico, the mountain zone consists of a series of separate ranges and mountain basins between the Rio Grande on the west and the Pecos river on the east. In northern New Mexico the mountains become prominent again, reaching elevations above 13,000 ft. (4,000 m.). Thence they sweep northward and northwestward through the United States, Canada and across northern Alaska to the Arctic ocean near Point Hope. As a whole the mountain system is about 4,700 mi. (7,600 km.) long. The section designated as the Rocky mountains extends only 2,200 mi., 1,290 mi. of which are in the United States. Its greatest width is attained in Utah and Colorado, where the system of ranges is 350 mi. across. In Colorado there are 55 summits surpassing 14,000 ft., Mt. Elbert (14,431 ft.) being the highest of the system outside of Mexico. Colorado contains more than 250 mountains between 13,000 and 14,000 ft. Northwest of Colorado breadth and elevation diminish until at the Canadian boundary the ranges are less than 100 mi. wide, with few elevations exceeding 9,500 ft. In Canada, for 450 mi., the system forms the boundary between British Columbia and Alberta. From Colorado almost to the Peace river in British Columbia, the Rockies carry the watershed of the continent (the continental divide). But this does not mean that they present a continuous chain of great peaks. On the contrary, the zone of uplift is rather a vast complex of separate ranges, interrupted at places by wide gaps of lofty rolling plateaus and intermontane basins or parks. In the Yukon territory of Canada, the system is a broken highland zone between the upper Yukon river on the southwest and the Mackenzie river on the east and northeast. At about 67° N. latitude the system swings westward across the border into Alaska and continues in a southwesterly arc to the Arctic ocean south of Point Hope. In Alaska the system is designated the Brooks range and contains the highest, most rugged mountain zone north of the Arctic circle, reaching heights a little over 9,000 ft.

Geology.—The Rocky mountain system is one of the younger systems of the world, although very old rocks are found at the core of many of the ranges. The major uplift of the system occurred in Late Cretaceous and Early Tertiary time, in what is called the Laramide revolution, about 70,000,000 years ago. However, the portion of the continent now occupied by the Rocky mountains had undergone a number of vicissitudes prior to its final uplift. Though individual ranges vary somewhat in their story, a generalized geologic history of the system includes the following events: the oldest rocks in the system were laid down as sediments in a shallow sea in Precambrian time—1,000,000,000 to 2,000,000,000 years ago. About 1,000,000,000 years ago this thick accumulation of shales, sandstones and limestones was compressed,

PRINCIPAL RANGES AND PEAKS OF THE ROCKY MOUNTAINS

folded and contorted by mighty forces within the earth's crust and uparched into an ancestral mountain system. The sedimentary rocks were altered by the heat and pressure into metamorphic rocks such as schist, slate, gneiss and marble. During the upheaval great masses of molten material were injected or melted their way upward into the core of the uplift. When it cooled, this material became granite. The processes of erosion now began to wear down this ancient mountain system. Rain fell; streams ate valleys into the surface; mud, silt and sand were carried out of the highlands into the adjacent water bodies. Gradually the uplift was carved into a rugged mountain system and then slowly reduced to a vast low-level plain, called a peneplain. Eventually the region again sank below the level of an encroaching shallow sea.

Throughout most of the two succeeding geologic eras, the Paleozoic and Mesozoic, the site fluctuated between low-lying swamp ground and shallow seas. In these seas were deposited a great depth of sedimentary material. Silt, mud and pebbles were carried down from highlands on the west. This material eventually consolidated into shales and conglomerates. Limey material was precipitated from sea water to form limestone. Sand accumulated along the shore and in river estuaries to form sandstones. The skeletons and shells of a complex assemblage of life forms were left in the sediments as fossils. These run a wide range from simple shells to dinosaurs. The depth of the sediments laid down during these times is very great. In some localities the total thickness from top to bottom is more than 10 mi. The greatest extent of sea occurred near the end of this episode, when a Cretaceous water body extended from the Gulf of Mexico to the Arctic ocean, and from the Mississippi to the Nevada plateaus. This vast continental trough with its great accumulation of sedimentary rocks is called the Rocky Mountain geosyncline.

Then at the end of the Cretaceous period, the bottom of the geosyncline began to arch upward. Great compressive forces from the west thrust folds and blocks of the thick sedimentary rocks upward and eastward along a zone from southern Mexico to western Alaska. Accompanying the uplift and folding was the breaking of great sheets and plates of rock, which were pushed eastward along nearly horizontal or gently dipping fractures (thrust faults) like cards in a deck pushed one over another. Displacement along some of these thrust planes is measured in tens of miles. Weakening of the earth's crust permitted molten material from below to break through in volcanic upheavals at numerous points, pouring forth lava and ash. Other steep angled faults were formed along the eastern margins of the emerging ranges. This vast upheaval was the Laramide revolution, taking its name from the Laramie range of Wyoming; it lasted through several million years.

During the upheaval and after its close, the processes of wind and water erosion ate away at the uplift, carving it first into a magnificent group of mountain ranges and eventually wearing it down again to a low peneplain. Then only several million years ago the peneplain was again uplifted as a broad highland plateau. The process of dissection was begun anew. By now many of the canyons and valleys were cutting down through the great masses of sedimentary beds to expose the old metamorphic and granite rocks which had comprised the ancestral Rockies over a billion years earlier. About 1,000,000 years ago the Pleistocene ice age capped all of the higher ranges with glaciers. These crept outward through the valleys, scouring them into their typical U-shaped profile and fretting the highlands with cirques and serrated ridges. The present-day configuration of most of the higher ranges can be traced to glacial scouring. Greatly diminished glaciers still are found in the high mountains from the Wind River range of central Wyoming northward.

Divisions.—The Rocky mountain system can be divided conveniently into six divisions. From south to north these are: (1) the Sierra Madre Oriental of eastern Mexico; (2) the southern Rocky mountains of New Mexico, Colorado and Utah; (3) the middle Rocky mountains of Wyoming; (4) the northern Rocky mountains of Montana and Idaho; (5) The Canadian Rockies of British Columbia, Alberta and Yukon territory; (6) The Brooks range of Alaska. There are natural gaps or low passes in the crest of the system between all of these divisions except one. The Rio Grande and Pecos uplands divide the Sierra Madre Oriental from the southern Rockies. The Wyoming basin (Great Divide basin) lies between the southern and middle Rockies. The Yellowstone plateau separates the middle Rockies from the northern Rockies. There is no natural break between the northern Rockies and the Canadian Rockies. The Yukon-Porcupine-Mackenzie lowland separates the Canadian Rockies from the Brooks range.

Sierra Madre Oriental.—The Sierra Madre Oriental serves as the eastern rim of the central plateau of Mexico from a point just north of Oaxaca to north of Monterrey, a distance of about 700 mi. (*See* MEXICO.) On the east it falls away abruptly to the gulf coastal lowland. Westward it descends gently onto the dissected central plateau. At the north the range is relatively low—5,000 to 7,000 ft. At the south, however, the range is met from the west by the primary east-west volcanic axis of the central plateau. At this junction stands Mexico's highest peak, the magnificent volcanic cone of Orizaba or Citlaltépetl (18,701 ft.). Nearby is Cofre de Perote or Nauhcampatépetl (14,045 ft.).

Southern Rockies.—In the Rockies of Colorado, the most magnificent groups are probably the Sawatch range (96 mi. by 32 mi.) and the Sangre de Cristo range (220 mi. long) in the central part of the state. In the southwestern corner the Elk, San Miguel (with the spectacular Lizard Head, 13,113 ft.), Needle and San Juan groups, form a wild and rugged mass of peaks.

The Wasatch mountains of central Utah, overlooking the great basin for 100 mi., present abrupt ranges. Associated with the Wasatch mountains is the Uinta group (96 mi. by 40 mi.), of which Kings peak (13,498 ft.) is loftiest.

Central Rockies.—The ranges just mentioned connect with the main axis of elevation of the Rockies in the region of Yellowstone park through a belt of rather indefinite uplands running north and south along the western boundary of Wyoming. There are the Crawford mountains, the Wyoming range, the Gros Ventre mountains, the Snake River range and the Teton range. The Teton range presents perhaps the most splendid spectacle of all the Rocky mountain ranges. It is 40 mi. long and 10 mi. wide, rugged and precipitous. Granite spires rise abruptly 6,000 to 7,000 ft. above the flats of Jackson's Hole. The principal peaks are the Three Tetons (Grand Teton, 13,766 ft.) and Mt. Moran (12,800 ft.) at the northerly extremity. Reverting to the continental divide of the western part of Wyoming, the important uplift of the Wind River range is next in order, northwest of Great Divide basin. It is about 100 mi. long; the core is more than 13,000 ft. in elevation and sends out long lateral ridges between which remarkable canyons occur. Its most prominent summits are Fremont peak (13,730 ft.) ascended in 1842 by John C. Fremont; Gannett peak (13,785 ft.), the highest in Wyoming, and Chimney Rock (13,340 ft.). Numerous small glaciers are on the northeast slopes. The largest, Dinwoody, covers several square miles.

Northeast of the Wind river range, across the Bighorn basin, lie the Bighorn mountains, a prodigious offshoot of the main range toward the great plains, 146 mi. long and 40 to 50 mi. wide. The axis averages 12,000 ft. in elevation, rising about 9,000 ft. above the neighbouring prairies. A few of the peaks surpass 13,000 ft. and bear small glaciers in their rugged amphitheatres. The highest is Cloud peak (13,165 ft.).

Northern Rockies.—Between the northern boundary of Yellowstone park and the Yellowstone river, the Beartooth and neighbouring ranges display what are probably the principal mountain masses of this division. In the vicinity of Mt. Cowen (11,206 ft.) and Emigrant peak (10,921 ft.) the relief becomes as great as 6,400 ft., and Granite peak (12,799 ft.), the highest mountain in Montana, is situated there, as are Grasshopper glacier and other small ice bodies. The Beartooth range has a score of summits of 12,000 ft. or more.

The continental divide, however, leaves Yellowstone park in a northwesterly direction. At the 114th meridian it swings off abruptly to the northeast through the Butte and Helena districts. Beyond this swing, the western axis of elevation continues northwestward as the Bitterroot mountains to within 125 mi. of the Canadian border along the boundary between Idaho and Montana. The average elevation is between 7,000 and 8,000 ft. The highest

peaks occur on projecting lateral spurs—Scott peak (11,393 ft.), El Capitan (9,936 ft.) and St. Mary (9,335 ft.). This 125-mi. interval is filled by the Coeur d'Alene (6,000 ft.) and Cabinet ranges, the latter culminating in Snowshoe peak (8,712 ft.). West of the Bitterroots in central Idaho lies a labyrinth of peaks and ridges (11,000 to 12,000 ft.); Borah Peak (12,662 ft.) is the highest point in that state.

In the region of Butte and Helena, Mont., the continental divide is generally featureless, the passes around Butte averaging 6,000 ft. or less. The Anaconda range contains Mt. Haggin (10,598 ft.) and Mt. Evans (10,635 ft.). Beyond Helena, the divide veers to the north-northwest and follows the Lewis range, which is so wild and rugged that no roads for vehicles cross it for 200 mi. Opposite the Lewis range, the westerly margin of the Rockies is defined by the Whitefish range (west of the north fork of Flathead river) and the Mission range (60 mi. long, southeast of Flathead lake). The latter culminates in the glacier-bearing McDonald Peak (10,300 ft.). Between the Mission and Lewis ranges is the Swan range (Mt. Holland, 9,272 ft.). The principal continental pass there is Marias pass (5,215 ft.), crossed by the Great Northern railroad. The finest scenery in this quarter is within Glacier National park (*q.v.*), with 20 peaks between 9,000 and 10,000 ft. and six between 10,000 and 10,438 ft. Mt. Cleveland is the loftiest summit. The park contains about 40 small glaciers and several large ones (from 2 to 5 sq.mi. apiece), besides a myriad of attractive lakes.

Canadian Rockies.—In Canada the axis of the Rockies is continuous for 1,000 mi. It is simpler, straighter and more sharply defined. Prominent passes of the divide are: Crowsnest pass (Canadian Pacific railway), 4,453 ft.; Vermilion pass (motor road), 5,376 ft.; Kicking Horse pass (Canadian Pacific railway), 5,320 ft., and Yellowhead pass (Canadian National railway), 3,717 ft. Proceeding northwesterly from the U.S. boundary, there are no glaciers for 100 mi., the peaks being mostly below 9,000 ft. A little farther on is Mt. Joffre (11,316 ft.), the first real glacier-hung peak. From there to beyond Mt. Robson (12,972 ft., the highest of all) the system is continuously alpine for about 285 mi. The Canadian Pacific railway crosses the chain 200 mi. from the boundary near the famous Lake Louise. Halfway between this and Mt. Joffre stands the handsome Mt. Assiniboine (11,870 ft.). In the 150-mi. gap between the Canadian Pacific and the Canadian National railways at Jasper, are situated Mt. Forbes (11,902 ft.) and Mt. Columbia (12,294 ft.), the fifth and second in rank in the Canadian Rockies respectively. In these mountains about 50 peaks surpass 11,000 ft. Glaciers and snow fields abound, and with the neighbouring groups just mentioned there is presented the best sweep of truly alpine territory to be found in North America outside of Alaska. The northwesterly 500 mi. of the range are imperfectly known, although the mountains are lower.

The Brooks Range.—Across northern Alaska, the Brooks range serves as a watershed between the Yukon river drainage and that of the Arctic ocean. It includes, from east to west, such separate mountain groups as the Davidson, Romanzof, Franklin, Philip Smith, Endicott, Schwatka, Baird and De Long mountains. The highest peak is Mt. Michelson (9,239 ft.) in the Romanzof mountains near the east end of the range. To the west the range crest lowers to 3,000–4,000 ft. Anaktuvuk pass (2,200 ft.) lies near the centre of the range. Almost the entire range is devoid of trees, being north of timberline. *See* also the articles on the states and provinces in which the Rocky mountains lie and on the national parks found in the Rocky mountains.

ROCKY MOUNTAIN SPOTTED FEVER AND OTHER SPOTTED FEVERS. Rocky mountain spotted fever is a typhuslike disease (*see* TYPHUS FEVER), first described in the Rocky mountain section of the U.S., caused by a specific microorganism (*Rickettsia rickettsii*) and transmitted to man by ticks. It is identical with a disease known as São Paulo fever in Brazil and with the spotted fever of Colombia. A closely related disease, but distinct etiologically, is *fièvre boutonneuse* caused by *R. conorii*, transmitted by ticks and occurring in the countries bordering on the Mediterranean sea and scattered localities of eastern and southern Africa.

History and Distribution.—Rocky mountain spotted fever was known along the Snake river in Idaho as early as 1873, but its first clinical description in a medical journal was given by E. E. Maxey in 1899. It was characteristically a disease of the open range and was noted to occur most frequently among hunters, trappers, fishermen, cattlemen and sheepherders. Up to 1930, it was thought to be confined to 11 states of the northwest, although one case was reported in Indiana. In connection with field investigations of endemic typhus in the southeastern U.S., it was noted that some cases in rural districts in the more northern states and among urban dwellers vacationing in the country were severe and did not exactly correspond to the clinical picture of endemic typhus. A high proportion of these patients had histories of tick bites within a short time preceding their illness. In 1931 L. F. Badger, R. E. Dyer and A. S. Rumreich recovered the causative agent from three patients who were residents of northern Virginia, and proved that it was identical with that of Rocky mountain spotted fever. After that time, the disease was shown to be widely distributed in the U.S., present in two provinces of western Canada, in two states of Brazil and in Colombia.

Discovery of the microbe of Rocky mountain spotted fever, by H. T. Ricketts in 1906, led to the understanding of other rickettsiae-caused diseases. (*See* RICKETTSIAE.)

Epidemiology.—The predominance of the disease in the western U.S. among persons exposed to the open range, and the seasonal limitations to late spring and early summer months, were explained when the vector (carrier) species was identified as a wood tick, *Dermacentor andersoni*. It is widely distributed in the adult form upon large mammals, particularly cattle and sheep, in the western range country of the Pacific coast states, Nebraska, North and South Dakota and Nevada, and from New Mexico and Arizona on the south to Alberta, Saskatchewan and British Columbia on the north. Adult ticks live two to four years or more. Engorged females deposit their eggs in the soil. The winter is passed in the adult, nymphal or egg stage. Larvae, or seed ticks, emerge in the late spring and seek a blood meal on small animals. If successful, they molt to the nymphal stage, which may not become active until the following spring.

Many small animals, especially rodents, are susceptible to infection with the rickettsiae of Rocky mountain spotted fever and after having been bitten by an infected tick develop an inapparent form of the disease. While the microorganisms are in the peripheral circulation, these animals serve as a source of infection for uninfected larval, nymphal or adult ticks which chance to feed upon them. The rickettsiae pass through the stage-to-stage development in the tick and are carried to successive generations in decreasing numbers by transovarial passage. The infection is thus maintained in nature by the alternation of the small animal and tick hosts. Among the rodent hosts should be mentioned particularly the jack and the cottontail rabbits. The rabbit tick *Haemaphysalis leporis-palustris*, although it does not attack man, is one of the vectors in maintaining continuous passage in small animals.

The occurrence of the human disease in the eastern and southern U.S. was explained when it was discovered that the common dog tick, *Dermacentor variabilis*, which attacks man also acts as a vector. Dogs and field mice are involved in maintaining the reservoir of infection. In the southwestern U.S. human cases were also traced to the lone star tick *Amblyomma americanum*. In Brazil the common vector is *Amblyomma cajennense*. Many other tick species were found to be experimentally infectable but were epidemiologically unimportant.

Clinical and Pathological Features.—The clinical course of the disease is essentially similar to that described for typhus fever (*q.v.*). In severe cases of spotted fever the rash tends to be more hemorrhagic and to be accentuated on the extremities, particularly about the wrists and ankles. Occasionally, a lesion may be detected at the site of the tick bite, but a typical primary eschar is lacking. Nervous and mental symptoms are common; restlessness, insomnia, disorientation and delirium are frequent manifesta-

tions of involvement of the central nervous system. Prostration may be marked from the beginning, merging into coma with death possible as early as the sixth or seventh day. Convalescence is apt to be slow and may be complicated by visual disturbances, deafness and mental confusion. Although recovery may be delayed, it is usually complete. The case-fatality rates, as in typhus, vary directly with age. The crude rate for reported cases in the U.S. is about 18%.

The underlying pathology is essentially the same as that of typhus fever. The microorganism (*R. rickettsii*) proliferates in the endothelial cells lining the smaller blood vessels, causing damage to the vessel walls with hemorrhage, infiltration with round cells and thrombosis. Lesions are widely distributed in the tissues of the body but are characteristically common in the central nervous system and skin. Occasionally, there may be large areas of subcutaneous hemorrhage, particularly in the scrotum. Diagnosis is confirmed by blood tests. The Weil-Felix reaction becomes positive with *Bacillus proteus* X 19 and usually with X 2 and negative with *B. proteus* X K during the second week of the illness. The complement-fixation test becomes positive about the same time. The microorganisms may be recovered and identified following inoculation of guinea pigs with blood obtained from a patient early in the course of the illness. Reports in the 1950s indicated that early institution of treatment with antibiotics—chloramphenicol (chloromycetin) and aureomycin—greatly shortens the disease and decreases the risk of death.

Prevention.—Prevention depends primarily upon exercise of personal care in protection against tick bites. Persons exposed to known infected areas should frequently examine the clothing and body for ticks. Usually the tick does not become attached to its host immediately but crawls about for several hours. The chance of receiving infection from the bite of a tick is directly proportional to the length of time that the tick has fed. Ticks should be removed from the person or from a pet with a small forceps or with a piece of paper. The skin area involved should be swabbed with an antiseptic and the forceps disinfected with heat or chemicals. Hands should be washed with soap and water after such an operation.

There is a satisfactory vaccination procedure against Rocky mountain spotted fever; it should be administered in the spring or early summer before the beginning of the tick season, and should be repeated annually as the maximum degree of protection conferred is for less than a year. The degree of immunity afforded is relative, but the chance for subsequent infection is lessened and the risk of death is greatly reduced.

Fièvre Boutonneuse (Fièvre Exanthématique).—A. Connor and A. Bruch in 1910 described a mild typhuslike fever which they believed to be an endemic disease of Tunisia, north Africa, and proposed the name boutonneuse fever. It was subsequently observed to occur in Marseilles, France, and still later was discovered to have a wide geographic distribution. It was reported from most of the Mediterranean countries and the Crimea. Available evidence suggests that the diseases described as Kenya typhus and South African tick-bite fever are probably identical with boutonneuse fever, although conveyed by a different species of tick. One review indicated the widespread distribution of this human tick-borne rickettsiosis in Africa.

Primarily, the vector was found to be a brown dog tick, *Rhipicephalus sanguineus;* subsequently, other ticks were incriminated. The microorganism is *Rickettsia conorii.* The reservoir probably exists in nature in the lower animals, but the dog is apparently an important source of infection. The course of the disease is somewhat similar to Rocky mountain spotted fever, but it is milder. The case fatality rate is less than 3%. A primary lesion, called a *tache noire* ("black spot") is frequently found. It is somewhat similar in appearance to the primary eschar characteristically seen in tsutsugamushi disease. It is, of course, located at the site of the infecting tick bite and, therefore, may be found on any part of the body, but usually on a part covered by clothing. The Weil-Felix reaction with X 19 strain of *B. proteus* becomes positive late in the disease. Experimental evidence suggested that both chloramphenicol (chloromycetin) and aureomycin would be highly effective in the treatment of boutonneuse fever. Prevention depends upon protection from tick bites as outlined above.

ROCOCO ART is a term which stands for trends in Baroque art that developed in France under Italian influence around 1720 and lasted until about 1770. Contemporaries called the style "modern," "style of the century," and *"genre pittoresque."* The term rococo was coined toward the end of the 18th century and originally had a derogatory connotation; it may have originated in the words *rocaille* and *coquille* ("rocks" and "shells"), which were common rococo motifs.

In France the style was applied primarily to the creation of secular buildings and furnishings for the court, the aristocracy, and the *bourgeoisie.* This vast sphere of influence was possible because the style was exceptionally adaptable and because it was widely popularized by quantities of ornamental engravings published in Paris and copied and paraphrased in Augsburg. Rococo ornament was characterized by arrangements of C- and S-curves prominent amid fanciful tracery, scrollwork, and other motifs derived from classical, Chinese, and even Gothic sources, as well as from nature. The design might be shaped in symmetric or asymmetric fashion, but it always was balanced and closely related to the overall pattern.

While the French creation caught the fancy of all of Europe, a unique development took place in south Germany and Austria which must not be gauged, as it often has been, by the Paris yardstick. In marked difference from its development in France, the German rococo was essentially placed in the service of the church. It is characterized by the unity of its effect; in a rococo church of this period, all media are fused and so tightly knit that it seems neither possible nor even important to unravel the contributions made by the various artists—architect, sculptor, painter.

Rococo trends dominated the 18th century, though others of less vigour persisted. All of them withered in the last quarter of the century when neoclassicism began to gain general recognition. *See* BAROQUE ART; BAROQUE AND POST-BAROQUE ARCHITECTURE; *see* also references under "Rococo Art" in the Index.

ROCROI, a fortress town of northeastern France, *département* of Ardennes, on the Belgian frontier, lies 18 mi. (29 km.) NNW of Charleville-Mézières by road. Pop. (1962) 1,542. It was heavily fortified in the 16th and 17th centuries. Nearby the Spanish were defeated by the Great Condé (Louis II de Bourbon) in 1643 (*see* THIRTY YEARS' WAR), but Rocroi was captured in 1658, only to be returned to France a year later by the Treaty of the Pyrenees. The fortifications by Vauban still encase the town in the form of a pentagon, and have great interest as an example of military architecture of the period before the development of modern artillery. (AR. E. S.)

ROD, ÉDOUARD (1857–1910), French-Swiss writer of psychological novels and pioneer of comparative criticism, was born at Nyon, Switzerland, on March 29, 1857. After his first novels written in Émile Zola's manner, the best of which was *Palmyre Veulard* (1881), Rod soon evolved his own highly sensitive, introverted psychological art, frequently depicting frail, tragic characters in such novels as *La Course à la mort* (1885), *Le Sens de la vie* (1889), *Nouvelles romandes* (1890), *La Vie privée de Michel Teissier* (1893; English translation, *The Private Life of an Eminent Politician,* 1893), and *Le Silence* (1894). Although often a prey to pessimism and despondency, Rod insisted more and more on duty, conscience, and renunciation as decisive elements of life. As a critic he was a forerunner of modern comparative literary study, his chief works being *De la littérature comparée* (1886) and *Reflets d'Amérique* (1905). He died at Grasse, France, on Jan. 29, 1910.

RODBERTUS, JOHANN KARL (1805–1875), German economist, author of a conservative interpretation of social reform and a strong supporter of monarchy and economic nationalism, was born at Greifswald on Aug. 12, 1805, the son of a university professor. Educated in law at Prussian universities, Rodbertus acquired in 1836 the landed estate of Jagetzow in Pomerania. Until his death, on Dec. 6, 1875, he carried on economic studies as well as historical studies and participated in Prussian politics.

The substance of his social-economic reasoning is a principle of government regulation of wages so that they might rise in proportion to increases in national productivity. Unlike Malthus and Ricardo—who believed that wages rise naturally in conformance with rising conceptions of a conventional standard of living—Rodbertus maintained that wage earners, when left to their own devices, cannot earn more than a bare minimum of physical existence. All increases of national productivity therefore accrue to the owners of property. Since property owners constitute a minority of the population, crises of underconsumption and retarded production occur while yet a majority of the population is not prosperous: "thus society pays dearly because labour is hired too cheaply."

Rodbertus, unlike Marx, did not call into question the entire complex of the political and economic institutions of capitalism, but in entrusting the government with legislating the conditions of wage payments, he furnished a conservative basis of state intervention; thus in his time he won support for social legislation in circles inaccessible to socialist agitation or fearful of it.

See H. Dietzel, *Karl Rodbertus: Darstellung seines Lebens und seiner Lehre* (1886); E. C. K. Gonner, *Social Philosophy of Rodbertus* (1899). (G. W. Z.)

RODENT, any member of the order Rodentia, characterized by teeth and jaws uniquely adapted to gnawing. The largest order of mammals, both in number of individuals and in number of described species, it includes squirrels, beavers, mice, rats, lemmings, jerboas, porcupines, chinchillas, and capybaras. They occur naturally in most parts of the world, being abundant and diversified in all continents except Australia, and in all continental islands. Members of the family Muridae invaded Australia from New Guinea during the Late Pliocene and Pleistocene, but have not yet spread beyond the northeastern part of the continent. The Norway and related rats (*Rattus*) and the house mouse (*Mus*) have accompanied man in his travels, and are found almost anywhere humans are.

GENERAL FEATURES

Most rodents are small to medium sized. The pygmy mice are among the smallest of mammals, while the capybara may become as large as a black bear, reaching a length of 4 ft. and a weight of 100 lb. Rodents occupy a wide variety of ecologic niches, most being terrestrial quadrupeds: some, such as pocket gophers and mole rats, have become modified for burrowing either with their forelimbs or with their incisor teeth; some, such as squirrels, are arboreal; others, such as flying squirrels, have developed skin folds that permit them to glide from one tree to another; a number, including jerboas, jumping mice, and kangaroo rats, have enlarged hind legs and have become bipedal leapers; and a few, such as beavers, muskrats, coypus, and the Australian water rats, have made adaptations toward an aquatic habitat (fig. 1).

Because of their small size and great reproductive capacity, rodents are among the few groups of mammals that successfully survive in a human-dominated environment. It is estimated that most U.S. cities contain nearly as many rats as humans, and house mice may be almost as abundant. Norway rats cause extensive damage to stored and processed human food supplies, and some rodents cause extensive damage to growing crops. The American muskrat, introduced into Europe, is a cause of great concern, especially in the Netherlands, because of its habit of making burrows in dikes. A number of rodents act as intermediate hosts for human diseases or for the parasites that carry such diseases. The brown or Norway rat is the chief carrier of fleas that can transmit bubonic plague. Tularemia can also be transmitted by rodents.

Rodents are an important food source for primitive people because of their abundance and relative ease of capture, but relatively few except squirrels are eaten by civilized people. Beavers, squirrels, muskrats, chinchillas, and coypus produce valuable furs. Beaver skins were one of the chief ingredients in the fur trade that was responsible in large part for opening the western United States.

Rodents, in general, are herbivorous, but many of them eat animal food to the extent that it is available, including insects, young birds, eggs, and even carrion.

CHARACTERISTIC STRUCTURES

Dentition.—Rodent dentition is characterized by a single pair of upper and lower chisellike incisors, which grow throughout the life of the animal. Since the enamel is limited to the anterior face of the tooth, wear removes the softer dentine faster than the enamel, thus preserving a sharp cutting edge. The growth of the incisors, measured in millimetres per week in most forms that have been studied, reaches one centimetre per week in the burrowing pocket gophers or geomyids. The constant rubbing of the upper incisors against the lower wears them away as fast as they grow.

Behind the incisors, there is a large gap, or diastema, in front

of the cheek teeth. The latter include a maximum of two upper and one lower premolars, and three upper and three lower molars on each side. The minimum is two pairs of molars above and below. The teeth show many different patterns, ranging from very simple in the squirrels to very complex in forms like the capybara; they also range from low crowned and rooted to very high crowned and rootless (fig. 2).

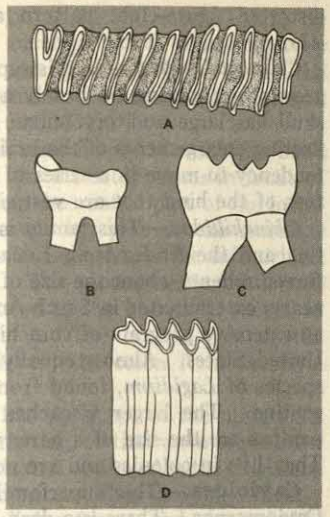

FIG. 2.—TYPES OF RODENT TEETH
(A) Surface view of a left upper molar of a capybara. This is the most complicated tooth among extant rodents (stippled areas are cement). (B, C, D) Side views of lower teeth: (B) low-crowned tooth of *Paramys* from cheek side; (C) molar, five-crested type, of *Theridomys*, from tongue side; (D) right molar, ever-growing type, of *Microtus*

Jaw Muscles.—The lower jaw is capable of anteroposterior movement at the point of articulation with the skull, which permits the cheek teeth to be used in chewing food, with the incisors disengaged, when the jaw is at the rear of the articulation; or the incisors to be used in gnawing, with the cheek teeth disengaged, when the jaw is moved forward (fig. 3).

Living rodents, with one exception (*Aplodontia*, the sewellel, or mountain beaver, of the Pacific Northwest), have evolved highly specialized jaw muscles, related to the use of the incisors in gnawing. The most important of these is the masseter, which is used to pull the lower jaw forward in gnawing. During the evolution of the rodents, the masseter has spread forward from its primitive point of origin on the cheek bone or zygomatic arch (as in *Aplodontia*), expanding either onto the snout in front of the bone; through the orbit, out the infraorbital foramen, and onto the snout; or by a combination of the two (fig. 4). J. F. Brandt, in 1855, divided what are now included in the rodents into three subdivisions on this basis, calling them the Sciuromorpha (squirrellike), Hystricomorpha (porcupinelike), and Myomorpha (mouselike). T. Tullberg, in 1899, noted that rodents could be divided into two groups, which he called the Sciurognathi (squirrel-jawed) and Hystricognathi (porcupine-jawed), on the basis of whether the angle of the jaw arises in the plane of the incisor or lateral to it. He then used Brandt's terms for subordinate units.

Digestive Tract.—Many rodents have cheek pouches, used for storing food to be transported to the nest or storage area. Usually these pouches open into the mouth, but in the New World Heteromyidae (pocket mice) and Geomyidae (pocket gophers), there are fur-lined pouches, opening outside the mouth, which reach back almost to the shoulders and which have a capacity about equal to the volume of the head. Rodents usually have a large alimentary pouch, or caecum (sometimes larger in capacity than the stomach), where digestion of plant tissues takes place.

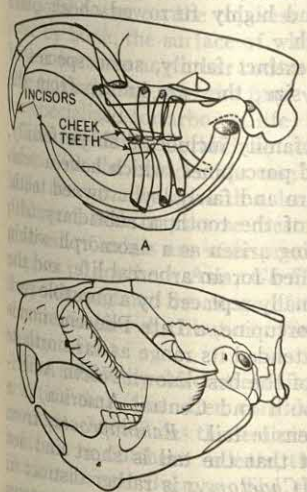

FIG. 3.—SKULLS OF RODENTS

CLASSIFICATION AND SURVEY

Formerly the order was believed to include two major types of mammals: the Simplicidentata, with a single pair of upper incisors; and the Duplicidentata, with two pairs of upper incisors. The Duplicidentata (rabbits and hares) are now separated by all American and most European specialists as a separate order, the Lagomorpha (*see* LAGOMORPH).

Difficulties in classification arise because the rodents, while being so abundant and successful an order, are limited in the possible directions of evolution by the initial acquisition of the gnawing adaptation. As a result, there has been a great deal of parallel evolution within the order, and relationships of different forms (and, hence, a true phylogenetic classification) are difficult to determine. All currently used classifications are merely attempts to reach a closer approximation to the correct phylogenetic arrangement. A. E. Wood's modified classification (1959) is used here, suborders being used for part of the order, whereas those rodents that cannot be shown to belong to suborders are left independent. In this article the order Rodentia is divided into four groups, three suborders—Protrogomorpha, Caviomorpha, and Myomorpha—and an independent category that comprises several families of uncertain subordinal affinities.

PRIMITIVE RODENTS (PROTROGOMORPHA)

The rodents of this suborder had the masseter muscle in its primitive position on the ventral surface of the zygomatic bone (fig. 4A). According to Wood's interpretation, this group includes the ancestral stock of the order. The infraorbital foramen is small or of medium size, and has no relationship to the masseter. The angle of the jaw may be incipiently sciurognathous, incipiently hystricognathous, or indeterminate. The cheek teeth may have cusps; if the cusps are united into crests, there are never more than four crests per tooth. The teeth are usually low crowned. Postorbital processes are normally absent. The tibia and fibula bones of the lower leg are not fused.

Ischyromyoidea.—The superfamily represents the initial (Eocene) radiation of the rodents. The premolar formula is $\frac{2}{1}$; *i.e.*, there are two premolars on either side of the upper jaw and one on either side of the lower jaw. These rodents are known from North America, Europe, and probably North Africa and Mongolia, from the Late Paleocene to the Late Oligocene.

Paramyidae.—This was a particularly abundant family in the Eocene of North America, and included all the known Paleocene rodents. In Wood's opinion, it was directly or indirectly ancestral to all other rodents. Paramyids ranged in size from animals the size of a house mouse to those as large as a beaver. The cheek teeth were cusped and low crowned. The skull somewhat resembled that of a marmot.

Sciuravidae, a family comprising small rodents derived from the paramyids, were abundant in the Middle Eocene of North America, and are represented in Mongolia. They appeared in the Early Eocene, and lasted till the end of that period. The teeth were four crested but generally low crowned and always rooted. This family may have been ancestral to the Myomorpha.

Protoptychidae, a poorly known family from the Late Eocene, was characterized by an inflated tympanic bulla, of the sort associated in living rodents with bipedal leaping locomotion. Skeletons have been discovered in Wyoming.

Cylindrodontidae, a family that occurred in the Late Eocene and Oligocene of North America and the Oligocene of Mongolia, contained burrowing forms with high-crowned to ever-growing cheek teeth, based on a four-crested pattern.

Ischyromyidae.—This family, known from the Oligocene of North America, had teeth that were four crested and low crowned.

Aplodontoidea.—A specialized superfamily of the Protrogomorpha, with high-crowned to ever-growing cheek teeth.

Aplodontidae.—This family has as its sole existing representative the sewellel, or mountain beaver (*Aplodontia rufa*), of the mountains of Oregon, Washington, and British Columbia. It is about the size of a marmot, with a short tail, small rounded ears, and small eyes. *Aplodontia* is a burrowing animal, living in damp woods. Other representatives of the family are known from the Tertiary of western North America, where the group was apparently rare but persistent. Side lines are known as fossils from Mongolia and Europe.

Mylagaulidae, a strange family of North American Miocene and

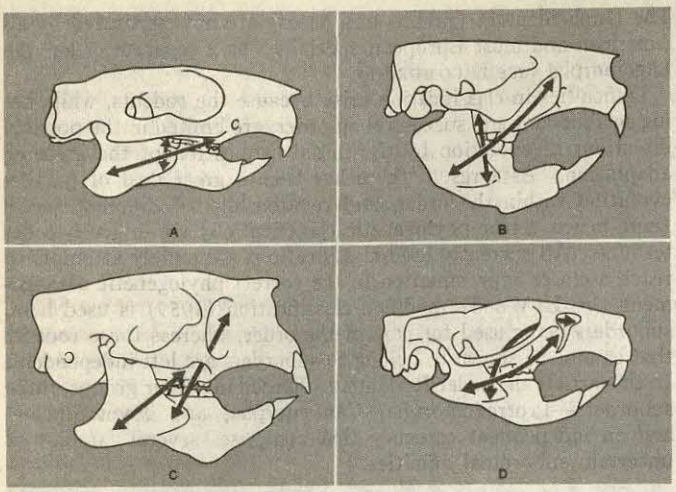

FIG. 4.—SKULLS OF THE FOUR BASIC TYPES OF RODENTS, SHOWING POSITION OF BRANCHES OF THE MASSETER MUSCLE

(A) Protrogomorphous, with masseter limited to zygoma; (B) sciuromorphous, with anterior branch of masseter shifting upward and forward on snout; (C) hystricomorphous, with deep branch of masseter shifting upward and forward through enlarged infraorbital foramen; (D) myomorphous, combining (B) and (C)

Pliocene forms, comprised burrowing members. Paired horns, present on the snouts of some individuals and absent on others, were perhaps a sexual characteristic.

Cavylike Rodents (Caviomorpha)

This suborder is characterized by an enlarged infraorbital foramen through which a branch of the masseter muscle passes to attach to the side of the snout (fig. 4C). This arrangement results in a much more anteroposterior direction for the pull of the masseter, and increases the efficiency of this muscle for gnawing. The jaw angle arises lateral to the socket of the lower incisors. The Caviomorpha are exclusively South American, except for geologically recent immigrants to North America; they have a cheek-tooth pattern based on four cross crests in both upper and lower teeth. Ancestral members of all four currently recognized caviomorph superfamilies are present in the Early Oligocene, when the group is first known. The tibia and fibula have generally been fused since the Middle Miocene. The premolars are reduced to $\frac{1}{1}$.

Octodontoidea.—This superfamily is the central stock of the Caviomorpha. The cheek teeth, though primitive and four crested, progressively develop an E-shaped pattern by the reduction of one of the crests.

Octodontidae, of southern distribution, contains a number of rodents that have secondarily simplified bilobed cheek teeth: Ctenomyinae includes the burrowing tuco tucos (*Ctenomys*); Octodontinae contains ratlike or mouselike forms with tufted tails, chiefly found in the southern Andes. *Spalacopus* and *Aconaemys* of the latter group are burrowers; they resemble *Ctenomys* but have cheek teeth with a figure-eight rather than a kidneylike pattern.

Echimyidae contains many rodents of ratlike appearance, with rooted cheek teeth and usually coarse or spiny hair. The cheek teeth have a distorted E pattern. In the Echimyinae the cheek teeth are narrow, whereas in the Dactylomyinae they are broad, with four crests. The fur is soft and the third and fourth digits are usually elongated in the Dactylomyinae.

Capromyidae includes two groups. The hutias (*Capromys*) of the Greater Antilles and northern South America are coarse-haired, robust rodents, with ever growing cheek teeth of the E pattern. The coypu, or nutria (*Myocastor*), is a large guinea pig-like rodent with soft fur, found from Brazil to Argentina and Chile, and introduced into both Europe and the United States.

Abrocomidae.—This family has only a single genus, *Abrocoma,* characterized by a ratlike appearance, short hairy tail, and inflated auditory bullae, a blisterlike bone that encloses the middle ear. The cheek teeth are ever-growing, the upper ones having a distorted figure-eight pattern and the lowers being E-shaped. *Abrocoma* lives in the Andes.

Chinchilloidea.—In this superfamily the cheek teeth are ever-growing, consisting of closely appressed, transverse plates. The skull has large auditory bullae and an inflated mastoid area, reflecting enlargements of the brain associated with a rather general tendency to move in a series of kangaroolike jumps. The lateral toes of the hind foot are vestigial or lost.

Chinchillidae.—This family is known from the plains of Argentina and the Andes from Ecuador south. Chinchillas are soft-furred rodents, about the size of a large squirrel. They have been nearly exterminated in South America by fur hunters, but there is an extensive program of chinchilla raising being carried on in the United States. Almost equally soft furred are the rabbit-eared species of *Lagidium,* found from Peru and Chile to southern Argentina. The larger viscachas (*Lagostomus*) of the Argentine pampas are the size of a hare, with large head and robust body. They live in colonies and are nocturnal.

Cavioidea.—This superfamily is the most successful of the Caviomorpha. There is a deep groove on the side of the jaw for the attachment of the deep portion of the masseter muscle. The cheek teeth are high crowned or ever-growing.

Caviidae includes the guinea pigs and cavies. The cheek teeth are ever-growing and prismatic, often being heart shaped in cross section. The clavicle is absent, and the lateral toes of the hind foot are lost. The tail is short or absent. *Cavia* includes a number of species, of which the best known is the guinea pig, which was domesticated by the Incas in Peru. *Kerodon* of Brazil has toes that end in blunt nails, almost resembling hooves. *Dolichotis,* restricted to Argentina, is rather rabbitlike, especially *D. patagonica,* the mara.

Hydrochoeridae, a Miocene derivative of the Caviidae, is characterized by large size and highly complex cheek teeth. *Hydrochoerus,* the semiaquatic capybara, is the only living genus. It is found from Panama to Paraguay, and is the largest living rodent. Pleistocene relatives of *Hydrochoerus,* as much as 10% larger, are known from both North and South America.

Dinomyidae.—This family consists of a single living species with a broad, flat skull and molars made up of four transverse plates. They are found in Peru.

Dasyproctidae includes the agoutis of tropical America. They are the size of large rabbits, with a short tail, and three toes on the hind foot. These active runners are locally prized for food.

Cuniculidae.—The Cuniculidae includes the paca, a large rodent with five-toed feet. The cheek teeth are lobed. The most striking peculiarity is in the enormous and highly furrowed cheek plate developed from the zygomatic arch.

Heptaxodontidae.—This is an extinct family, some species of which exceeded the capybaras in size; they are known from the Pleistocene of the West Indies.

Erethizontoidea.—This superfamily includes a single family, the Erethizontidae, or New World porcupines, which have a relatively primitive cheek-tooth pattern and fairly low-crowned teeth. Four crests form the main part of the tooth, a subsidiary fifth crest, present in some forms, having arisen as a neomorph within the family. The skeleton is modified for an arboreal life, and the first toe of the hind foot is functionally replaced by a movable pad. *Erethizon,* the North American porcupine, a Late Pliocene immigrant from South America, has extended its range as far north as Alaska and Labrador, and is one of the best-known North American rodents. *Coendou,* from South and Central America, is a smaller animal, with a long prehensile tail. *Echinoprocta,* from Colombia, is like *Coendou* except that the tail is short and not prehensile. The South American *Chaetomys* is rather distinct in having simple cheek teeth, well-developed postorbital processes on the skull, and spines restricted to the head and forelimbs. The tail is long and scaly.

Mouselike Rodents (Myomorpha)

This suborder may be defined as small sciurognathous rodents, with cheek teeth primarily cusped and low crowned; the premolars

are reduced to $\frac{1}{1}$ or $\frac{1}{0}$, or may be absent. Locomotion is by scampering, climbing, burrowing, or leaping, the last being very common. The masseter muscle has grown forward along the snout, either in front of the zygoma or both in front of it and through the infraorbital foramen (fig. 4D).

Muroidea.—This is the typical superfamily forming the basis of the Myomorpha. A branch of the masseter passes in front of the eye, onto the snout, compressing the ventral part of the infraorbital foramen into a slit, while another part of the masseter passes into the orbit, through the dorsal part of the infraorbital foramen and out onto the snout. The premolars have all been lost, and the cheek teeth are reduced to the molars $\frac{3}{3}$, except in the Hydromyinae where they are $\frac{2}{2}$. The cardiac part of the stomach is lined by a cornified layer; the colon forms a spiral loop.

Cricetidae.—This large family has the cusps of the molars arranged in two rows, generally alternating, so that worn teeth show a pattern of zigzag crests. Cricetids first appeared in the Oligocene of Europe and western North America. They are only slightly more primitive than some of the living forms, and are probably derivable from Eocene sciuravids like *Pauromys*.

The subfamily Cricetodontinae are primitive members of the family, appearing in the Lower Oligocene of Europe and North America. The cusps are the dominant parts of the tooth pattern, although there are five transverse ridges, subsidiary to the cusps. These ridges have become dominant in the other subfamilies, which originated from the Cricetodontinae during the Miocene or Pliocene.

The subfamily Cricetinae includes a wide variety of common rat- and mouselike rodents of the Northern Hemisphere, as well as some that have spread farther south. The hamsters, including *Cricetus* and relatives, are heavy-bodied, short-tailed burrowing rodents of Europe and Asia. *Peromyscus,* the white-footed or deer mouse, is an abundant American member from Alaska to Panama. Other cricetines include the pack rats (*Neotoma*); harvest mice (*Reithrodontomys*), with grooved incisors; the grasshopper mouse (*Onychomys*), which feeds largely on insects and other small animals; and rice rats (*Oryzomys*), found from Patagonia to New Jersey. There are a large number of tropical American genera.

The subfamily Nesomyinae, from Madagascar, includes forms descended from ancestors that accidentally reached the island, probably in the Pliocene. Some are burrowers, others scamperers. Some authors consider that they are sufficiently distinct to be recognized as a separate family. *Lophiomys,* the maned rat of eastern Asia, is given subfamily rank because of its peculiar skull. The temporal fossa, on the top rear of the skull, is completely roofed over by bone, the surface of which is granulated. No such condition is found in any other rodent. The teeth are typically cricetid. The tail is bushy, and the feet, with a partly opposable first digit, are specialized for arboreal life.

The subfamily Gerbillinae consists of the gerbils, jumping rodents with the broad brain case and inflated mastoid and auditory bulla that usually go with a leaping habit. The cheek teeth are prismatic, with transverse crests. The upper incisors are usually grooved. Gerbils are widespread in the deserts of Africa and the steppes of southern Asia, *Gerbillus, Tatera,* and *Meriones* being found throughout the range of the subfamily, with others having a more limited distribution. Several genera use the tail for the storage of fat.

The subfamily Microtinae is so very distinct from the other cricetids that it is often considered to be a distinct family, Microtidae. It includes the lemmings (*Lemmus* and allies), typically holarctic or northern rodents, though they extend as far south as Guatemala and Burma. The cheek teeth are high crowned and prismatic, rarely with roots, and the crown has a complex zigzag pattern. The skull is angular, marked with ridges for the attachment of muscles. In general, microtines are heavy-bodied, short-tailed animals, more or less modified for burrowing. The largest microtine is the muskrat (*Ondatra*), a valuable fur-bearing animal in North America. It has been introduced into Europe. The muskrat is semiaquatic, with a long, dorso-ventrally flattened tail and partially webbed hind feet. Its relationships to the other microtines are traceable through *Neofiber,* the round-tailed muskrat of Florida, and *Arvicola,* the Eurasian water vole. Such genera as *Clethrionomys,* the red-backed vole of northern areas; *Phenacomys,* the red tree mouse of North America; and *Ellobius,* a burrowing vole of southern and central Asia, are primitive in having rooted cheek teeth. The microtines are one of the latest important groups of mammals to have developed. They originated in the Pliocene from the Cricetinae, through *Mimomys,* first described as a fossil and later discovered still living in the mountains of central Europe. *Mimomys* was also present in North America during the Pliocene.

Muridae.—This family, of southeast Asiatic origin, is now widespread throughout the world. The only New World forms are the semidomesticated *Rattus* (house, Norway, roof, black, or wharf rats) and *Mus* (house mouse). The upper molars have three rows of cusps, which generally unite to form cross crests. The family is especially abundant in the East Indies, which probably is the approximate area of its origin from the Cricetidae during the Miocene.

The subfamily Murinae contains the true rats and mice, with about 400 recognized species. *Rattus* is abundant and diverse in southeast Asia and the East Indies. The bandicoot rats, *Nesokia* and *Bandicota,* are burrowers, found from Egypt to China and Malaysia. *Cricetomys,* the African giant rat, may measure 30 in. in total length. The spiny mice, *Acomys,* of East Africa, southwest Asia, Cyprus, and Crete, are almost as spiny as hedgehogs. Various unrelated genera have become arboreal, developing common adaptations. A number of genera of shrew rats (*Mycteromys, Echiothrix, Melasmothrix*), with long, narrow heads and shrewlike appearance, are found in the East Indies. The Philippine shrew rat (*Rhynchomys*), with minute cheek teeth and short, weak incisors, perhaps feeds on insects and worms. Bushy-tailed rats (*Phloeomys* and *Crateromys*) occur in the northern Philippines. Some members of the subfamily reached Australia, apparently in the Pleistocene, and have begun a rapid diversification, bipedal leaping locomotion being the most notable development.

The water rat subfamily, Hydromyinae, ranges in Australia, New Guinea, and the Philippines. These rodents apparently evolved from the Murinae in New Guinea. Normally there are only two of the usual three molars, which have broad, basined crowns. The infraorbital foramen is wide. The feet are large, and the hair is dense and waterproof, both adaptations to life in the water.

The subfamily Dendromurinae, the African tree mice, is characterized by an arboreal life and a reduced number of cusps in the molars. The first digits are opposable, and the claws are frequently modified into nails. Another African group, the Otomyinae or swamp rats, also belongs in the Muridae.

Geomyoidea.—This superfamily includes the two New World families of the pocket gophers (Geomyidae) and the pocket mice and kangaroo rats (Heteromyidae). These two families are certainly closely related. The Eomyidae, an extinct family best known from the Late Eocene and Oligocene of Europe and the United States, is referred to this superfamily on the basis of similarities in skull structure, especially in the base of the skull. External fur-lined cheek pouches are present in the two living families. There is a single pair of upper and of lower premolars, except in the most primitive eomyids, where there is a second pair of upper premolars.

Geomyidae.—The pocket gopher family includes stout-bodied, short-tailed burrowing forms with massive, uninflated skulls. Members of the living subfamily, Geomyinae, have small eyes and ears and large claws on the forefeet. They are found in western North America, Central America, and northern South America. The cheek teeth are reduced to simple, ever-growing prisms; unworn teeth, however, show the ancestral pattern.

The subfamily Entoptychinae, abundant in the Miocene of western United States and Florida, developed into a dominant group of rodents at the expense of the Cricetidae. The general structure was similar to that of the geomyines, but the skulls were less angular and the tooth structure was intermediate between that of the

geomyines and the heteromyids. Usually the teeth are lower crowned than in the geomyines.

Heteromyidae, like the Geomyidae, is characterized by external fur-lined cheek pouches. Some forms are leaping (*e.g.,* kangaroo rats), whereas others are mouselike and scampering (*e.g.,* pocket mice). The subfamily Perognathinae, or pocket mice, appeared in the Oligocene and became commoner in later deposits of western United States. The cheek teeth are rooted and show the primitive pattern for the family. The four cusps of the lower premolar unite in the middle of the tooth to form an X pattern. Heteromyinae, the subfamily of spiny pocket mice, separated from the perognathines during the Oligocene; its members were very abundant in western United States and Florida during the Miocene, though they are now restricted to Middle America and northern South America. They are identified by the presence of spiny hairs among the fur, and by differences in the tooth patterns, especially in that the lower premolar develops a series of cusps surrounding a central basin. The subfamily Dipodomyinae, the kangaroo rats, originated in western United States in the later Tertiary. The most striking feature of these rodents is the elongation of the hind limbs for leaping, with which is associated a great inflation of the auditory bullae and adjacent parts of the skull, and a widening of the entire posterior part of the skull. The teeth are high crowned and, when worn, show great similarities to those of the geomyids.

Eomyidae.—This fossil family is known mostly from teeth and jaws, together with a few skulls. Eomyids probably had a scampering mode of locomotion. The teeth are cricetidlike, but there are always premolars (absent in the cricetids), as well as differences in detail of pattern. The skull is similar to that of geomyids and heteromyids, to which they are probably related. The Eomyinae is a fossil subfamily, known from Late Eocene and Oligocene of Europe and North America, and Pliocene of western United States; it was abundant in mouse-sized forms. The subfamily Yoderimyinae, of the Late Eocene or Early Oligocene of Wyoming and Texas, is rare and poorly known.

Dipodoidea.—This is a superfamily of jumping rodents, including the jerboas and jumping mice. The infraorbital foramen is large, intermediate in size between the myomorphous and hystricomorphous conditions. The cheek teeth are $\frac{4}{3}$, the first upper one (the only premolar) being very small.

Zapodidae.—The most primitive living members are in the subfamily Sicistinae, including the Eurasian *Sicista,* or birch mouse, a tree-living and seed-eating animal. The Zapodinae, or jumping mice, of North America and east Asia contains species that have developed leaping locomotion but show no inflation of the auditory bulla (which may support the contention of those who believe that the inflation of the bulla is a desert adaptation rather than a leaping one, since the jumping mice inhabit non-desert areas). Fossils are known since the Early Miocene.

Dipodidae.—The jerboas are one of the most successful families of leaping rodents, and one of the most highly specialized for this mode of locomotion. The hind legs are long and the three middle metatarsal bones are usually fused, the lateral toes being lost. The hind feet are long. The bullae and mastoids are inflated. Jerboas are found in desert and steppe areas of northern Africa, eastern Europe, and Asia. They probably evolved from early zapodids.

Gliroidea.—This is an exclusively Old World superfamily of small rodents. The infraorbital foramen is sciuromorphous. The cheek teeth are usually $\frac{4}{4}$ (though the premolars may be lost), and have a very distinctive pattern. They probably were derived, via the European Eocene-Oligocene *Gliravus,* from protrogomorphs like the sciuravids or small paramyids.

Gliridae, the dormouse family, comprises arboreal forms with bushy tails. In general appearance, they are intermediate in most features between squirrels and mice. The edible dormouse, *Glis,* ranges across southern Europe into Asia Minor. *Muscardinus,* the common dormouse, about the size of a house mouse, is found from England to the Mediterranean and Asia Minor. Various other genera exist in Eurasia and Africa. The African species are sometimes separated as the subfamily Graphiurinae, with less developed crests on the cheek teeth and a primitive attachment of the lateral branch of the masseter muscle. The dormice found in southeastern Asia, including India and China, are generally separated as the subfamily Platacanthomyinae, though some authors consider them to be a distinct family. *Typhlomys,* a Chinese member of this group, is unique because it is a burrower with greatly reduced eyes.

Seleviniidae.—This family has been established for the peculiar central Asian *Selevinia,* an aberrant dormouse that has evolved into a leaping form, with a long, jerboalike tail, inflated auditory bullae, and short front legs. The molars have large central basins, and are reduced in size.

Spalacoidea.—The Old World mole rats and bamboo rats are another group of related families, presumably also related to the same stock as the others here included in the Myomorpha. They are burrowers.

Spalacidae, including *Spalax,* the blind mole rat of southern Europe, Egypt, and western Asia, is a family of highly developed burrowers similar in body form to the pocket gophers.

Rhizomyidae is the bamboo rat family of India, China, and the Malay region. It includes the east African mole rat (*Tachyoryctes*); one of the smaller members of the family, it is about eight inches long.

Independent Members

The remaining 13 families of rodents, recognizably distinct from the types already mentioned, cannot be placed in any of the existing suborders with certainty.

Sciuroidea.—This superfamily contains only the single family Sciuridae, the squirrels.

Sciuridae.—Some authors consider this family to represent the most primitive type of rodent. There seems to be little justification for this view except in the pattern of the cheek teeth, which are very primitive, though they are more evolved than in the least specialized members of the Paramyidae. Post-orbital processes of the frontal are always present. The small infraorbital foramen is compressed by the sciuromorphous masseter muscle. The premolars are usually $\frac{2}{1}$. The family is represented everywhere except in polar areas and in Australia and the oceanic islands.

Sciurinae is the subfamily of tree and ground squirrels. The typical squirrels of Eurasia and America (*Sciurus*) include the American gray and the European red squirrels, both of which have been widely introduced outside their native ranges. The North American red squirrel (*Tamiasciurus*) is a smaller form. The pygmy squirrels (*Microsciurus*) of Central and South America are but little larger than mice. The tree squirrels of Africa and India are large, including *Ratufa* of the Indo-Malaysian area and *Funambulus,* the palm squirrel of India. There has been extensive diversification of the squirrels in Africa. Another subgroup includes the Oriental *Callosciurus* and related forms, some of which have become ground living, especially in the East Indies. One, *Rhinosciurus,* has slender incisors and is largely insectivorous.

The spiny squirrels of Africa include *Xerus* and its relatives. They are largely ground-living species, found all over Africa south of the Sahara. The cheek teeth are much more complicated than in other squirrels, as a result of which S. Schaub (1958) considers that they belong in a distinct family.

The ground squirrels of North America and Eurasia may be recognized as a distinct subdivision of the Sciurinae, the tribe Marmotini. Chipmunks (*Tamias* and *Eutamias*) are well-known small, striped rodents with cheek pouches; they are good climbers. *Tamias* is found in eastern North America; *Eutamias* in western North America and eastern Asia. The spermophiles, susliks, or ground squirrels (*Citellus*) are found from Hungary through Asia and in western North America, south to Mexico. They are primarily plains dwellers. The tail is short and flattened. The related prairie dog (*Cynomys*), of western North America, lives in colonies. The marmots or woodchucks (*Marmota*), found from the Alps across Asia and throughout North America as far south as Alabama and New Mexico, are the largest of the squirrel family.

The flying squirrels, subfamily Petauristinae, are found through-

out the forested parts of the Northern Hemisphere. The fore and hind limbs are connected by a broad skin fold, supported by a cartilaginous spur from the wrist. Using this fold, they glide from tree to tree. The largest forms (*Petaurista* and *Eupetaurus* of southeast Asia and the East Indies) reach a head and body length of two feet. The European *Sciuropterus* and the American *Glaucomys* are much smaller. Several other genera are found in Malaysia.

Castoroidea.—In this superfamily the masseter muscle is similar in its attachments and divisions to that in the Sciuridae, but there are no postorbital processes and the cheek teeth are very different. In modern forms, the teeth have complex patterns and are ever-growing, although the earliest known forms (from the Oligocene) have low crowns and a tooth pattern that, while still complex, is derivable from a four-cusped ancestral pattern.

Castoridae.—This family of burrowing rodents, abundant during much of the Tertiary, is now reduced to two species of a single genus, *Castor,* comprising the European and American beavers. The latter is a semiaquatic rodent that builds dams, thus impounding ponds. *Castoroides* of North America and *Trogontherium* of Europe and Asia were large Pleistocene forms, the size of a black bear. In all castorids, the premolars are reduced to $\frac{1}{1}$.

Eutypomyidae.—This was an aberrant North American Late Eocene to Miocene family characterized by two upper premolars and an exceedingly complicated pattern in the cheek teeth. The foot structure was peculiar; the exact adaptations of the group are uncertain. They apparently were related to the beavers.

Theridomyoidea.—This very abundant superfamily of the European Eocene and Oligocene was typically hystricomorphous in infraorbital foramen but sciurognathous in jaw structure. American authors have usually considered them to be highly aberrant and specialized, whereas many European authors allocate them to a central position in rodent evolution.

Pseudosciuridae, a European Eocene and Oligocene family with low-crowned teeth. The earliest forms are close to the Paramyidae; later ones lead directly into the Theridomyidae.

Theridomyidae.—This family is known from the Middle Eocene to the Oligocene of Europe. Early species had low-crowned cheek teeth with five crests; later species had high-crowned or even ever-growing cheek teeth.

Hystricoidea.—There is a single family that can be referred to here, the Hystricidae or Old World porcupines. They differ from the New World porcupines (Erethizontidae) in dwelling on the ground. *Hystrix* includes large rodents, two feet or more in length, with short tails and peculiar inflated snouts; they range over southern Europe, Asia, and Africa. *Atherurus,* widespread in Africa and southern Asia, is about the size of a large rat. Other genera are also small. The family is a classic example of a hystricomorphous and hystricognathous rodent group.

Thryonomyoidea.—This superfamily comprises two very distinctive living African rodents that are hystricomorphous and hystricognathous. The group frequently was considered to have special relationships with the caviomorphs; their similarities are now thought to be due to parallel evolution. These two families have been shown to be descended from the Phiomyidae.

Thryonomyidae.—The African cane rats (*Thryonomys*) are about 15 to 18 in. long, not counting the tail. The incisors are broad and powerful, the cheek teeth, $\frac{4}{4}$, are high crowned and rapidly lose their pattern. Many of the hairs are modified into spines. The milk premolars are retained throughout life.

Petromuridae.—The rock rat (*Petromus*) of southwest Africa is about eight inches long. The structure of the skull suggests closer relationships with the Thryonomyidae than with any other rodents. The milk premolars are retained throughout life.

Phiomyidae.—This family appears in the Oligocene of Egypt and was very abundant and diverse in the Miocene of Africa. The Oligocene forms show the initial stages in the retention of the milk teeth. The Miocene forms developed superficial similarities to many rodents from other parts of the world.

Bathyergoidea.—A single family, the Bathyergidae, or South African mole rats, belongs here. They are hystricognathous, but not hystricomorphous. *Bathyergus* burrows with its large claws, and has normal rodent incisors. All other members of the family burrow with their incisors as well. The incisors have been modified so that they extend out in front of the mouth; as a result, the bases of the upper incisors extend back into the palate, or even into the pterygoid bones of the skull, instead of ending in front of the cheek teeth as in all other rodents. The bathyergids are the most specialized burrowers among the rodents, never coming to the surface of their own free will.

The remaining three families of rodents are of completely uncertain relationships. All three have a hystricomorphous masseter muscle and a sciurognathous jaw angle, but other features suggest no close relationships among them.

Anomaluridae.—This is a family of arboreal rodents with gliding membranes similar to those of the flying squirrels. Cheek teeth are $\frac{4}{4}$ and are high crowned. One genus, *Zenkerella,* does not possess the flying membrane. The family is from Africa south of the Sahara, and few fossils are known.

Ctenodactylidae, also African rodents, are found in general north of the Sahara. They are about the size of a gray squirrel. The cheek teeth are prismatic and ever growing. Related fossils are known from the Oligocene of Mongolia and the Miocene of India and North Africa.

Pedetidae.—This family includes *Pedetes,* the springhaas or jumping hare of eastern and southern Africa, the largest bipedal jumping rodent, standing about 18 in. high, two to three times the size of any other leaping rodent. The front legs are small, and the tail is long and bushy. The cheek teeth, $\frac{4}{4}$, are very high crowned. Related forms, from the Miocene of Africa, are even more specialized than the extant genus.

See separate articles on various rodents and references under "Rodent" in the Index; *see* also MAMMAL.

(A. E. Wo.)

RODEO, a series of cowboy contests deriving from the days of the early cattle industry of the southwestern plains of the United States when men, forced to spend months and even years on the range, would gather together in the "cowtowns" at the end of the trails and vie for the unofficial title of best bucking horse rider, roper, etc., the contests being accompanied by heavy betting. As the cowboy was curtailed in scope by the railroads and fencing, the contests became regular, formal programs of entertainment.

Many western towns and areas claim the distinction of being the first place to hold a rodeo in the United States, among them Cheyenne, Wyo., in 1872 and Winfield, Kan., in 1882, but at best such early contests were merely exhibitions of riding and roping skill and not the highly organized shows that modern rodeo became. Denver, Colo., is traditionally accepted as the birthplace of paid spectator rodeo, October 1887.

Formerly, as now, various titles were given to these shows, such as stampede, frontier day, roundup, or fiesta. The word rodeo, which is of Spanish origin, did not come into general use until the 1920s. Originally an outdoor sport, rodeo moved indoors in 1917 at the Stockyards Coliseum in Fort Worth, Tex., thus becoming a year-round sport with a season extending from the second week in January until the end of December.

Both professional and amateur rodeo programs are built around the five standard events: saddle bronc riding, bareback riding, calf roping, bull riding, and steer wrestling. Other events such as team roping, steer roping, steer decorating, wild cow milking, and barrel and a variety of other races are added as facilities and funds permit. The specialty numbers, such as trick riding, fancy roping, and the dog, horse, and steer acts (known as contract acts) are held simultaneously or spaced in the program to permit officials to prepare chutes, equipment, etc., for following contests. Integral parts of every rodeo are the queen and clown, the latter

serving a useful purpose in distracting the attention of the contest animals while the dismounted or thrown rider has a chance to leave the arena. Other features such as mounted quadrilles and allied western classes may be presented, and often a popular motion-picture or television star entertains.

Organized on Nov. 1, 1936, and originally called the Cowboy's Turtle Association, the Rodeo Cowboy's Association (RCA) raised the standards of rodeo. The RCA represents the contestants' interests and regulates their personal behaviour and the types of shows to be entered, provides insurance for contestants, and establishes a system of fines and black lists to regulate managers' and contestants' activities. In 1929 the Rodeo Association of America, an organization of rodeo managers and producers, was founded to standardize events, rules, judging, and arena conditions and to work out common problems pertaining to the production of professional rodeos. In 1946 the group was renamed the International Rodeo Association (IRA). In 1959 the IRA was renamed International Rodeo Management, Inc. (IRMI). The RCA established its own point award system, naming an all-around champion and champions in the five standard events, team roping, and steer roping each year.

Rodeo contestants originally were the working cowhands of the West; today they come from all parts of the country. This highly specialized field demands a great degree of skill and stamina of the professional contestants, who may compete in as many as 80 rodeos during the year; participation does not guarantee a living, since events to be remunerative must be won, and the contestant is continually faced with the hazards of accidents and injury.

Rodeo stock is valuable, and the horses and bulls are well cared for to the point of being pampered. Good bucking horses are not from wild herds or killers but are usually halterbroken and gentle until mounted. They are encouraged in their dislike of being mounted and further annoyed by the flank strap, which is placed around the hind quarters; any foreign object on the rear of a horse has a tendency to make him buck.

After the end of World War II, rodeo became an important amateur sport among small saddle clubs, high schools, colleges, and even prisons in the United States. This resulted in formation of the National High School and National Intercollegiate Rodeo Association and the American Junior Rodeo Association. Rodeo spread to other parts of the world, becoming especially popular in Canada and Australia. (L. Sr.; E. W. Co.)

RODERIC (Ruadri; Rory O'Connor) (d. 1198), king of Connaught and the last high king of Ireland. He succeeded his father Turloch O'Connor as king of Connaught in 1156 but did not wrest Turloch's title of high king from Muirchertach O'Lochlainn of Ulster until ten years later, when O'Lochlainn fell in battle. He then attacked Dermot Mac Murrough (*q.v.*), king of Leinster, and divided his territory. Dermot's quest for help from England (1166) brought about the Anglo-Norman invasion of Ireland. Roderic's attempt to defend Dublin (1170) was unsuccessful, and after besieging the city (June–September 1171) he was routed by a Norman sortie and retreated to Connaught. Gradually all the Irish except Roderic and the northern rulers submitted to Henry II. Roderic sent envoys to England who concluded the Treaty of Windsor (1175) by the terms of which Roderic became Henry's vassal for Connaught and was recognized as overking of territory unconquered by the Normans; he was to pay an annual tribute of hides. There is no record that he did so, and Henry continued to grant to Anglo-Norman adventurers land nominally under Roderic's rule. Milo de Cogan, constable of Dublin, invaded Connaught in 1177; Roderic defeated him at Tuam, capturing and blinding his own son Murchad who had aided the enemy. From about 1186 Roderic was opposed by members of his own family and was for a time expelled from his kingdom. In 1191 he retired to a monastery and died at the Abbey of Cong to the north of Lough Corrib in 1198. (A. Gw.)

RODEZ, a town of southern France, and *préfecture* of the *département* of Aveyron, is situated 75 mi. (121 km.) NE of Toulouse on a defensive site at the confluence of the Auterne and Aveyron rivers, near the western margin of the Causses between the limestone Causse du Comtal to the north and the crystalline plateau of Lévezou to the south. Pop. (1962) 20,438. Roman Ruthena was the centre of the tribal area of the Rutheni, and later Rodez was the chief town of the district of Rouergue and the seat of a bishopric from 401. The duality of its development in the Middle Ages, with twin towns, the episcopal *Cité* and the feudal *Bourg,* each with a separate wall, has been imprinted in the town plan. Two distinct nuclei are evident: the *Place de la Cité* with the cathedral, and the *Place du Bourg.* The Cathedral of Notre Dame is a fine Gothic structure dating from the 13th to the 16th centuries. It has a great rose window in its main façade and a tower that rises to 290 ft. (88 m.). Nearby is the episcopal palace. Near the *Place du Bourg,* in what was the count's town, is the Romanesque Church of St. Amans. There are several fine old houses. Rodez is the administrative and service centre for the surrounding district, and its old-established woolen industry survives. It is a tourist centre of growing importance. (Ar. E. S.)

RODGERS, RICHARD (1902–), one of the most successful composers of popular music of his time, was born in Hammels Station, Long Island, N.Y., on June 28, 1902. He began to write songs in his early youth and between 1919 and 1923 studied at Columbia University and the Institute of Musical Art, N.Y. In 1918 he met Lorenz Hart, who became his librettist. Among the products of their collaboration, which lasted until Hart's death in 1943, were the musical comedies *A Connecticut Yankee* (1927), after Mark Twain; *On Your Toes* (1936); *Babes in Arms* (1937); *I Married an Angel* (1938); *The Boys from Syracuse* (1938), after Shakespeare's play *A Comedy of Errors; Pal Joey* (1940); and *By Jupiter* (1942).

Later he was associated with the younger Oscar Hammerstein, who wrote the texts for their productions until his death in 1960. Their first musical comedy, *Oklahoma!* (1943), was an immediate success, and was awarded the Pulitzer Prize. *Carousel* (1945) and *Allegro* (1947) were somewhat less successful, but *South Pacific* (1949) became widely popular and was awarded the Pulitzer Prize in 1950. There followed *The King and I* (1951), remarkable for its exotic character; *Me and Juliet* (1953); *Pipe Dream* (1955); *The Flower Drum Song* (1958); and *The Sound of Music* (1959). Rodgers also wrote the music for the documentary film *Victory at Sea* (1952), for which he was awarded the Distinguished Public Service Award by the U.S. Navy.

See D. Ewen, *Richard Rodgers* (1957). (N. Sy.)

RODIN, (FRANÇOIS) AUGUSTE (RENÉ) (1840–1917), French sculptor, was born in Paris on Nov. 12, 1840. From 1854 to 1857 he was a pupil at the Petite École de dessin (later renamed École des Arts Decoratifs); then, having been refused admission to the École des Beaux-Arts, he began to earn his living as an ornament maker and became an assistant to the sculptor A. E. Carrier-Belleuse. His "Man With a Broken Nose" (1864), which was rejected by the Salon, early revealed his ability. In 1871 he was in Brussels, working for Carrier-Belleuse on the "Caryatides" of the new Bourse and also undertaking a certain amount of work on his own account. In 1875 he visited Florence and Rome, where he was much impressed by the works of Donatello and Michelangelo.

BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, GIFT OF THOMAS F. RYAN, 1910

"THE THINKER" BY AUGUSTE RODIN. IN THE METROPOLITAN MUSEUM OF ART, NEW YORK

Rodin's plaster maquette of "The Bronze Age," exhibited in the Salon of 1877, attracted considerable attention; the modeling, indeed, was so fine as to give rise to the accusation of its having been cast from a living man. In 1880, however, when he exhibited his "John the Baptist Preaching" and the final bronze of "The Bronze Age," Rodin

silenced his critics and established his position in the world of sculpture. Thenceforward, he was to receive commission after commission; and the first of them was from the French government, which ordered a door for the Musée des Arts Decoratifs, with a series of bas-reliefs representing scenes from Dante's *Divine Comedy*.

Rodin worked on this commission for the rest of his life. His original idea was to divide the door into panels, as Ghiberti had divided his "Gate of Paradise" for the baptistery in Florence. One panel was to represent Paolo and Francesca; another was to show Ugolino devouring his children; and the upper part of the door was to contain a seated figure of Dante himself (eventually entitled "The Thinker"). However, his old friend Alphonse Legros then invited Rodin to London (1881–82), and there Rodin made a close study of the illustrations of Dante by John Flaxman and William Blake; thereafter, he abandoned architectural considerations entirely and no longer followed Dante's text. The project underwent many changes, and Rodin's studio was filled with works begun as components of the door and then set aside. The plaster maquette of "The Gate of Hell" (1917), which was finally cast in bronze in 1938, constitutes the last version of the project that Rodin left, but there is no doubt that he would have worked still longer on it had he lived. He died at Meudon on Nov. 17, 1917.

"The Gate of Hell" does, in fact, show Ugolino, Paolo and Francesca among swirling processions of damned souls; and "The Thinker" occupies the lintel. However, a number of other works which are now quite separate from "The Gate" were originally conceived also as subsidiary themes for it. These include "Adam" (1880), "Eve" (1881), "The Fair Armouress" (François Villon's Belle Heaulmière, 1885) and "The Prodigal Son" (1889). Even "The Kiss" (1886), often regarded as Rodin's masterpiece, was originally conceived to form part of "The Gate" as a figure of Faith.

Other sculptures commissioned from Rodin were "The Burghers of Calais," "Victor Hugo" and "Balzac." The first of these, which was not set up in Calais until 1896, is based on Jean Froissart's account of the famous incident and shows the burghers going barefoot, with nooses round their necks, to deliver the keys of Calais to the king of England. (There is a replica of this on the embankment at Westminster.)

The "Victor Hugo" was commissioned by the state for the Panthéon in 1889, but the first maquette (1890), which showed the poet seated with the upper part of his body naked, proved to be unacceptable. Rodin eventually produced a standing version, which was set up in the garden of the Palais Royal in 1909 but withdrawn afterward. The "Balzac" was commissioned by the Société des Gens de Lettres in 1891. The maquette, sent to the Salon in 1898, consisted of a block nearly ten feet high, with the subject's head emerging from the folds of a voluminous dressing gown. This provoked an indignant outcry, but the bronze cast of it was eventually set up on the Boulevard Raspail in 1939. Meanwhile, Rodin was producing other sculptures, including "Thought" (1886) and a series of portrait busts. The latter may be counted among his finest achievements; they comprise "Dalou" (1883), "Victor Hugo" (1883), "Rochefort" (1884), "W. E. Henley" (1884), "Octave Mirbeau" (1889), "Puvis de Chavannes" (1891), "Gustave Geffroy" (1905), "Clemenceau" (1911) and "Pope Benedict XV" (1915).

In 1900, Rodin's reputation stood so high that he could envisage a special exhibition of his work as a feature of the Paris universal exhibition. Altogether 168 examples were assembled, and an unprecedented success was achieved. The sculptor received the homage of Europe. Among Rodin's later works, mention must be made of the series of "Hands," in which hands are made to exemplify some literary or moral idea. This theme may perhaps be traced back to 1898, when he produced "The Hand of God" as an image of creativity. "The Hand of the Devil," holding a woman, appeared in 1903, "The Secret," or "Prayer," in 1910 and "The Hand Coming Out of the Tomb" in 1910 also. At the same time, Rodin turned toward literature; his conversations on art were collected by Paul Gsell and published as *L'Art* in 1910 (Eng. trans., *Art*, 1912); and his book, *Les Cathédrales de France*, appeared in 1914.

From 1908, Rodin was living in the former Hôtel Biron, where the state had provided accommodation for a number of artists and writers. There, Rainer Maria Rilke, a close friend of Rodin's, suggested that they should establish themselves together, and Rodin thereupon offered to bequeath all the works of his own that remained in his possession, all his collections and his villa at Meudon to the French state, on condition that he be allowed to spend the rest of his life in the Hôtel Biron and that on his death the building be converted into a Rodin museum. The hotel and the villa now constitute the two sections of the Musée Rodin, which contains most of Rodin's sculpture, his drawings, some paintings, his library and his art collections.

Numerous replicas of Rodin's sculptures can be seen in museums outside France. The Rodin museum in Philadelphia, inaugurated in 1929, is an architectural copy of the villa at Meudon.

RODNEY, GEORGE BRYDGES RODNEY, BARON (1718–1792), English admiral, who won several important naval battles against French, Spanish, and Dutch forces, was born in Feb. 1718. He was sent to Harrow, being appointed, on leaving, by warrant dated June 21, 1732, a volunteer on board the "Sunderland." While serving on the Mediterranean station he was made lieutenant (1739) on the "Dolphin." In 1742 he attained the rank of post captain, having been appointed to the "Plymouth." After serving in home waters, he obtained command of the "Eagle" (60 guns), and in this ship took part in Admiral Hawke's victory off Ushant (Oct. 14, 1747) over the French fleet. In 1749 he was appointed governor and commander in chief of Newfoundland, with the rank of commodore, and two years later was elected to Parliament for Saltash.

During the Seven Years' War (*q.v.*) Rodney rendered important services. In 1757 he had a share in the expedition against Rochefort, commanding the "Dublin" (74 guns). Next year, in the same ship, he served under Boscawen at the taking of Louisburg (Cape Breton). In 1759 and again in 1760 he inflicted great loss on the French transports collected on the Normandy coast for an attack on Great Britain. Elected M.P. for Penryn in 1761, he was in October of that year appointed commander in chief of the Leeward Islands station, and within the first three months of 1762 had reduced the important island of Martinique, while both St. Lucia and Grenada had surrendered to his squadron. At the peace of 1763 Admiral Rodney returned home, having been during his absence made vice admiral of the blue and having received the thanks of both houses of parliament. In 1764 Rodney was created a baronet. From 1765 to 1770 he was governor of Greenwich hospital. In 1771 he was appointed rear admiral of Great Britain, and in 1778 admiral of the white. From 1771 to 1774 he held the Jamaica command, and during a period of quiet was active in improving the naval yards on his station. Election expenses and losses at play in fashionable circles had shattered his fortune; he could not secure payment of the salary as rear admiral of Great Britain; and he lived for some time in Paris until the generosity of a friend enabled him to meet his debts.

Sir George was appointed once more commander in chief of the Leeward Islands late in 1779. His orders were to relieve Gibraltar on his way to the West Indies. He captured a Spanish convoy off Cape Finisterre on Jan. 8, 1780, and eight days later defeated the Spanish admiral Don Juan de Langara off Cape St. Vincent, taking or destroying seven ships. On April 17 an action, which, as a result of the carelessness of some of Rodney's captains, was indecisive, was fought off Martinique with the French admiral

Guichen. Rodney, acting under orders, captured the valuable Dutch island of St. Eustatius on Feb. 3, 1781. It had been a great entrepôt of neutral trade, and was full of booty, which Rodney confiscated. As large quantities belonged to English merchants, he was entangled in a series of costly lawsuits.

After a few months in England, recruiting his health and defending himself in parliament, Rodney returned to his command in Feb. 1782, and a running engagement with the French fleet on April 9 led up to his crowning victory off Dominica, when with 36 sail of the line he defeated the comte de Grasse, who had 34 sail (April 12). The French inferiority in numbers was counterbalanced by the greater size and superior sailing qualities of their ships, yet five were taken and one sunk after 11 hours' fighting. This important battle for Jamaica was a blow to French naval prestige, and it enabled Rodney to write: "Within two little years I have taken two Spanish, one French, and one Dutch admiral."

On his return to England Rodney received a barony and a pension of £2,000 a year. From this time he led a quiet country life till his death (May 24, 1792), in London.

Rodney was unquestionably an able officer, but he was also vain, selfish and unscrupulous, both in seeking prize money and in using his position to push the fortunes of his family. He made his son a post captain at 15, for example. He was accused by his second-in-command, Samuel Hood, of sacrificing the interest of the service to his own profit, and of showing want of energy in pursuit of the French after his victory off Dominica on April 12, 1782, but it must be remembered that he was then old and racked by disease.

RODÓ, JOSÉ ENRIQUE (1872–1917), Uruguayan philosopher, essayist, and educator, hailed by Spanish-Americans as their philosopher par excellence, was born in Montevideo on July 15, 1872. Patterns of life and human conduct were his primary concern; respect for freedom, tolerance, and justice guided his career.

Ariel (1900), his most extensive essay, written in a typical, majestic prose style, defines Rodó's moral credo, a cult of beauty and truth, a yearning for growth and inner harmony, a quest for a fuller life for individuals and the community. Próspero, the venerable teacher in *Ariel,* cautions his young listeners (as did Rodó throughout his life: as university professor in 1898, as journalist, as director of the National Library, and, in 1902 and 1908, as member of the Chamber of Deputies) not to be impressed by material triumph but to use their own spiritual, moral, and intellectual resources to strive for a well-rounded life. Individual self-scrutiny must result in enlightened action for the good of the group.

Continuing his probing of human behaviour and the development of character in *Motivos de Proteo* (1909), he set down his message in one sentence: "Reformarse es vivir" (to reform oneself is to live). *El Mirador de Próspero* (1913), a series of essays on political and cultural themes (among them are fine tributes to Bolívar, Juan María Gutiérrez, and Juan Montalvo), sums up his philosophy.

Despite his affinities with classical and French culture, and his cosmopolitan spirit, devotion to America and its people pervades his writings. Like Bolívar a century before him, he envisaged Spanish America as a cultural entity. Rodó died at Palermo, Italy, on May 1, 1917, on one of his rare journeys abroad.

RODRIGUES, an island dependency of the self-governing British colony of Mauritius, which lies 365 mi. W in the western Indian Ocean. Rodrigues is 9½ mi. (15 km.) from east to west and a maximum of 4½ mi. (7 km.) from north to south. Area 40 sq.mi. (104 sq.km.).

With Mauritius and Réunion, Rodrigues lies on a submarine ridge trending northeast–southwest. Like the other Mascarene Islands it is wholly volcanic in origin, being composed of a central ridge of doleritic lava reaching 1,290 ft., partly surrounded by a raised coral reef, studded with islets and separated from the land by a shallow lagoon of varying width. There are two passages through the reef; the northern, leading to Port Mathurin, is normally used.

The climate is dominated by the southeast trades from April to October and from November to March by the belt of converging air known as the doldrums. In summer it is oppressively hot and humid, but in the winter can be quite bracing. In summer, tropical cyclones frequently pass over or close to the island; Rodrigues experiences many more of these than does Mauritius.

The island was initially covered with dense forest, but only a few areas of bush remain. The greater part is now grass-covered from the effect of goats, cattle, and cultivation aided by burning.

Of the endemic mammalian fauna of Rodrigues, the sole survivor is the fruit-eating bat (*Pteropus rodericensis*). The giant land tortoise, now surviving only on the Aldabra Islands (Seychelles), has only recently become extinct. Thirteen species of endemic birds are known, and the caves of the limestone platform have yielded many skeletons of the now extinct solitaire (*Pezophaps solitaria*). The fauna is now dominated by introduced species, including deer, pigs, rabbits, rats, goats, and cattle among the mammals; guinea fowl are numerous. An important feature is the absence of malaria, which never reached the island. Other diseases common in Mauritius are also absent.

The population in 1962 was 18,335, giving a density of 458 per square mile. With an annual death rate of about 8 per thousand and a birth rate around 40, population increase is rapid. The majority of the people are of African origin, though few are unmixed. Most of the lighter-skinned people are in Port Mathurin. The black montagnards of the interior are descended from slaves introduced in the final reoccupation of the island after 1810. Except for a few Indians and Chinese, almost the whole population is Creole-speaking and Roman Catholic. Port Mathurin, with 671 inhabitants, is the only town. Rural settlement is scattered with a concentration on the northern side, and the small village of Gabriel lies in the centre of the island.

Rodrigues or Diego Ruy's Island was discovered by the Portuguese in 1645. In 1690 the Dutch government sent a body of French Huguenots to the Island of Bourbon (later Réunion), but they, finding the French in possession, proceeded to Rodrigues where eight of them landed in 1691. The colonists left the island in 1693 and made their way to Mauritius. From the Dutch the island passed to the French, who colonized it from Mauritius. Large estates were cultivated and the islanders enjoyed considerable prosperity. In 1809–10 Rodrigues was seized by the British, in whose possession it remained. The abolition of slavery proved disastrous to prosperity, and by 1843 the number of inhabitants declined to about 250. The population has since grown steadily, mainly by natural increase. There has been no large-scale immigration from India (as in Mauritius), as the sugar industry has never become established on Rodrigues and there have been no plantations to act as importers of labour. On balance Rodrigues has for decades been a net exporter of people.

Rodrigues is administered by a magistrate and civil commissioner from Mauritius, advised by a council of 17 islanders set up by the Mauritius government. There is a small police force and the health and agriculture departments have resident officers. The three small hospitals have 70 beds in all. Living standards are low and housing extremely poor. Most houses are built of wood and fibre and have only one room. Though there is little starvation, nutrition is generally inadequate and the plight of many old people is extreme. The island has two government and four aided primary schools.

A small export of salted fish, beans, onions, lemons, and livestock, entirely to Mauritius, is the only cash economy. Rodrigues depends almost entirely on subsistence cultivation of maize (corn) on peasant holdings; the crop is liable to severe fluctuations through cyclone damage in summer and drought loss in winter. Beans are an important dietary supplement and some fruit and vegetables are grown. Most families keep a few cattle or goats pastured on the grass slopes of the central ridge. There is already severe pressure of population on land, with less than half an acre of arable land per head. Soil erosion is widespread and serious, but anti-erosion work is actively pursued.

Fishing within the reef is important, though primitive in organization. The bulk of the catch is, however, salted and sold through Chinese traders to Mauritius. Trade depends on the irregular visits of vessels from Mauritius, when peasants bring their surplus crops and livestock to the port. Production is on a joint family basis; there is no larger-scale organization for production, mutual aid, marketing, or storage. Labour migration has long been an important source of livelihood. Rodriguans work in Mauritius and in its lesser dependencies such as Diego Garcia.

Transport depends on human and animal porterage, and on small vessels operating within the reef. There are no roads outside Port Mathurin. Rodrigues has a cable station on the route between Durban, S.Af., and Perth, Austr. (HA. C. BD.)

RODRÍGUEZ FRANCIA, JOSÉ GASPAR: *see* FRANCIA, JOSÉ GASPAR RODRÍGUEZ.

ROE, later changed by deed poll to VERDON-ROE, the name of two English brothers who were aviation pioneers.

SIR (EDWIN) ALLIOTT VERDON-ROE (1877–1958), British aircraft designer, the first Englishman to construct and fly his own airplane. He was born at Patricroft, near Manchester, Eng., on April 26, 1877, and educated at St. Paul's School, London. He went to British Columbia at the age of 14, but returned a year later and served a five-year apprenticeship at the Lancashire and Yorkshire Railway's locomotive shops. He then spent two years at sea, after which he entered the motor industry. On June 8, 1908, he flew a distance of 75 ft. in a biplane of his own design with a 24 hp.-Antoinette engine, nearly a year before the first officially recognized flight in England (by J. T. C. Moore-Brabazon, later Lord Brabazon of Tara, in 1909). He founded the aviation firm of A. V. Roe and Co., Ltd., with his brother, Humphrey, in 1910. Avro aircraft were used with great success in World War I and Avro 504N airplanes were the standard training aircraft for the Royal Air Force for a long period between World Wars I and II. Verdon-Roe later turned his attention to the design of flying boats, founding Saunders-Roe, Ltd., of Cowes, Isle of Wight. Knighted in 1929, he died on Jan. 4, 1958.

HUMPHREY VERDON-ROE (1878–1949) was born at Patricroft, near Manchester, Eng., on April 18, 1878. Commissioned in the Manchester regiment, he served in the South African War, retiring from the army soon afterward. He joined the firm of Everard and Co., webbing manufacturers in Manchester, and when his elder brother, Alliott, founded the firm of A. V. Roe and Co., he cooperated with him. He was not a pilot, but flew much as a passenger and in 1917 joined the Royal Flying Corps as an observer. In 1918, he married Marie Carmichael Stopes and with her founded the first birth control clinic, at Holloway, London, in 1921. He died in London on July 25, 1949. (D. CR.)

ROE, SIR THOMAS (*c.* 1581–1644), English diplomat and author, was born at Low Leyton, near Wanstead in Essex, and was educated at Magdalen College, Oxford. Through family influence he was appointed esquire of the body to Queen Elizabeth I, and in 1605 he was knighted by James I. His career as a diplomat began in 1615 when, at the request of the English East India Company, he was sent as ambassador to the court of Jahangir, the Mughal (Mogul) emperor of Delhi. During the four years of his mission he greatly advanced the interests of the company. As ambassador to the Ottoman Empire at Istanbul from 1621 to 1628, Roe obtained increased privileges for the English merchants trading in the Levant. In 1624 he negotiated a treaty with Algiers, then subject to Istanbul, which resulted in the liberation of several hundred English prisoners who had been captured by the Barbary pirates. He also mediated a peace treaty between Poland and the Ottoman Empire.

Roe returned to England early in 1629 and in September helped to negotiate the truce of Altmark between Gustavus II Adolphus of Sweden and Sigismund III of Poland, which left Gustavus Adolphus free to intervene on the Protestant side in the Thirty Years' War. Gustavus Adolphus sent him a gift of £2,000, but from the English government Roe received little financial reward for these services. Finally, in 1637, after six years spent in retirement, he was appointed chancellor of the Order of the Garter and in 1638 was given an annual pension of £1,200. Roe was the English representative at conferences held at Hamburg (1638), Ratisbon (1641), and Vienna (1642), where attempts were made to end the Thirty Years' War. Meanwhile, in 1640 he was made a privy councilor and was elected a member of the Long Parliament for the University of Oxford. He participated actively in the commercial debates but after his return from Vienna his health began to fail. In July 1643 he gained the permission of the House of Commons to retire to Bath, where he died in November 1644.

Roe's journal of the mission to the Mughal, several times reprinted, was reedited with an introduction by W. Foster for the Hakluyt Society under the title *Embassy of Sir T. Roe to the Court of the Great Mogul,* two volumes (1899). Of his correspondence, *The Negotiations of Sir T. Roe in His Embassy to the Ottoman Porte (1621–28)*, volume i was published in 1740, but the work was not completed and letters relating to Roe's mission to Gustavus II Adolphus (1629–30) were edited by S. R. Gardiner for the Camden Society miscellany, volume vii (1847). Several of his parliamentary speeches, dealing with trade, currency, and financial questions, were also published. (R. C. JO.)

ROEBLING, JOHN AUGUSTUS (1806–1869), U.S. civil engineer, designer of many great suspension bridges, among which the Brooklyn Bridge is the most famous, was born at Mühlhausen, Prussia, on June 12, 1806. Soon after his graduation from the polytechnic school at Berlin he moved to the United States, and in 1831 began to practise his profession in western Pennsylvania. He established near Pittsburgh, Pa., a wire rope factory, and in May 1845 completed his first important structure, a suspended aqueduct across the Allegheny River. This was followed by the Monongahela suspension bridge at Pittsburgh and several suspended aqueducts on the Delaware and Hudson Canal. Moving his wire factory to Trenton, N.J., he began in 1851 the erection at Niagara Falls of a long-span wire suspension bridge with double roadway, for railway and vehicular use (*see* BRIDGES), which was completed in 1855. Because of the novelty of its design, the most eminent engineers regarded this bridge as foredoomed to failure; but, with its complete success, demonstrated by long use, the number of suspension bridges rapidly multiplied, the use of wire ropes instead of chain cables becoming virtually universal.

The completion, in 1867, of the still more remarkable suspension bridge over the Ohio River at Cincinnati, O., with a clear span of 1,057 ft., added to Roebling's reputation, and his design for the great bridge spanning the East River between Manhattan and Brooklyn, New York City, was accepted. While personally engaged in laying out the towers for the bridge, Roebling received an accidental injury, which resulted in his death, at Brooklyn, from tetanus, on July 22, 1869. The bridge was completed under the direction of his son, Washington Augustus Roebling (1837–1926).

See H. Schuyler, *The Roeblings: a Century of Engineers, Bridgebuilders and Industrialists* (1931); D. B. Steinman, *The Builders of the Bridge* (1945).

ROEMER, OLE (OLAUS) (1644–1710), Danish astronomer who discovered that light travels at a finite speed, was born at Aarhus, Jutland, on Sept. 25, 1644. In 1662 he became the pupil and amanuensis of Erasmus Bartholinus at Copenhagen, and in 1671 he assisted Jean Picard in determining the position of Tycho Brahe's observatory (Uraniborg, on the island of Hven). Roemer went to Paris with Picard in 1672 and spent nine years on observations at the new Royal Observatory and at hydraulic works at Versailles and Marly-la-Machine. After a scientific mission to England (1679), on which he met Sir Isaac Newton, Edmund Halley, and John Flamsteed, Roemer returned to Copenhagen in 1681 as royal mathematician and professor of astronomy in the university. He also held several public offices, including that of mayor in 1705. He died at Copenhagen on Sept. 23, 1710.

Roemer discovered the finite velocity of light, which was suggested to him by his observations on the eclipses of Jupiter's moons. The first noteworthy transit instrument was erected at his house in 1690. He also set up at the university observatory an instrument with altitude and azimuth circles, and an equatorial

telescope, and built and equipped the "Tusculan" observatory at Vridlösemagle, near Copenhagen. The great fire of Oct. 21, 1728, destroyed his manuscripts except those discussed by J. G. Galle in *O. Roemeri triduum observationum astronomicarum a. 1706 . . . institutarum* (1845).

See A. Nielsen, *Ole Rømer* (1944); E. Stromgren, *Ole Rømer som Astronom* (1944).

ROENTGEN, DAVID (1743–1807), German cabinetmaker to Queen Marie Antoinette, was born at Herenhag on Aug. 11, 1743, and died at Wiesbaden on Feb. 12, 1807. He was the eldest son of Abraham Roentgen, who in 1750 moved to Neuwied, on the Rhine near Coblenz, where he produced furniture of outstanding quality, often decorated with inlay work of ivory and other material, much of it for the courts of German princes. David Roentgen learned his trade in his father's workshop and succeeded to the business in 1772, his father continuing as a partner until 1784. His father's firm having already achieved renown in Germany, the son won European reputation after he had displayed his furniture in Paris in 1779 and secured King Louis XVI, Queen Marie Antoinette and other members of the French court as customers. Roentgen was appointed cabinetmaker to the queen and in 1780 was granted admission as master (*maître ébéniste*) to the trade corporation of Paris cabinetmakers, a fact which made it possible for him to keep in Paris a stock of the furniture manufactured at Neuwied. In this fashion he was able to compete with such great French cabinetmakers of the period as Jean Henri Riesener and others. King Frederick the Great of Prussia and Empress Catherine II of Russia were also customers of Roentgen. The latter, after Roentgen's first visit to St. Petersburg in 1783, bought great quantities of his furniture. When in 1795 the French Revolutionary armies threatened to cross the Rhine, Roentgen evacuated his establishment and moved his stock of furniture farther inland. While he never succeeded in starting production again, former apprentices of his whom he had helped to establish in Berlin (David Hacker) and in Brunswick (Christian Härder) were successful in their enterprises.

Roentgen had begun his career by continuing and developing the style of furniture his father had introduced. His so-called French style is characterized by furniture of curved outline sometimes decorated with rich carvings. His "English" cabinetwork is based on elements dating from the early years of George III and occasionally influenced by Thomas Chippendale. Both types of furniture are frequently decorated with rich inlay work of outstanding charm and elegance made up of a variety of woods, some tinted and composed to form figural and floral compositions, often in the *chinoiserie* manner. Between 1775 and 1780 Roentgen's previous style is altogether abandoned and rigid, classical forms are introduced, the effect of which is often based on the contrast of mahogany with rich bronze appliqués. The Roentgen workshop indulged in mechanical devices which made appear or disappear drawers and mirrors by pressing on hidden releases. Peter Kinzing was the mechanical genius who invented many of these tricks and provided clockworks. Furniture by Roentgen is in most large museums in Europe, at the Metropolitan Museum of Art in New York and at the Art Institute of Chicago.

See Hans Huth, *Abraham und David Röntgen und ihre Neuwieder Werkstatt* (1938). (Hs. H.)

ROENTGEN, WILHELM CONRAD: *see* RÖNTGEN, WILHELM CONRAD.

ROERMOND, a town and seat of a bishopric in the province of Limburg, Netherlands, lies on the right bank of the Maas at the confluence of the Roer, 28 mi. (45 km.) NNE of Maastricht by rail. Pop. (1960) 25,728. Within the limits of the old fortifications (now replaced by boulevards) the medieval street pattern has remained intact. Among noteworthy buildings are the Late Romanesque minster (restored), and the early-15th-century Church (cathedral from 1661) of St. Christopher. Chemicals, electrical equipment, paper, clothing, and cigars are manufactured; there is also a large egg-packing station. A prosperous centre of the cloth trade in the 14th and 15th centuries, Roermond was a domain of the counts and dukes of Gelderland until 1543. Subsequently it was under Spanish, Austrian, French, and Belgian domination. During World War II it was heavily damaged. (P. J. Bu.)

ROESELARE (Fr. ROULERS), a town of West Flanders, Belg., on the Mandel River, 25 mi. (40 km.) SSE of Ostend. Pop. (1961) 35,645. It was rebuilt after World War I. Surviving historic buildings are: the Late Gothic Church of St. Michael (1497–1504), with a notable early-17th-century carved pulpit; the late-15th-century Grey Sisters' House; and the town hall and Seminary church, both of the 18th century. Roeselare is an educational centre. It has rail and road connections with neighbouring towns, and the canal to the Lys River (1872) has encouraged industrial and commercial expansion. In the Middle Ages it was a centre of the linen trade. It is the birthplace of the composer Adriaan Willaert (*q.v.*) and of the Flemish poet Albrecht Rodenbach (1856–80); the poets Guido Gezelle (*q.v.*) and Hugo Verriest (1840–1922) lived there. (G. J. D.)

ROGALAND, a *fylke* (county) of southwestern Norway. Area 3,531 sq.mi. Pop. (1960) 229,555. The district of Jaeren, south of the open Boknfjord, is a shelf of lowland richly covered by morainic drift; eastward the land rises to a rather barren upland; in the southeast valuable deposits of ferrotitanium ores are mined. North of Bokn the lowland continues over Karmøy, the most densely populated island in Norway. In its inner (eastern and northern) parts Bokn is split in long narrow branches penetrating far inland between precipitous walls. Beyond the heads of the fjords the mountains reach 3,000–5,000 ft. (900–1,500 m.). Jaeren is the most important dairy-farming district in Norway. Canning of fish, pottery, shipbuilding, and shipping are the predominant industries. Stavanger (*q.v.*) and Haugesund are the largest towns; traffic between them is maintained by fast hydrofoils as well as by conventional ferries. Sola International Airport is 9 mi. (14 km.) SW of Stavanger, which is connected by rail with Oslo. (L. H. Hg.)

ROGATION DAYS, in the Christian Church, comprise the Major Rogation (*litania maior*) on April 25 and the Minor Rogations (*litaniae minores*), the three days before Ascension Day. They are days of prayer and fasting, for the benefit of the crops. *See* PROCESSION; LITANY.

ROGER I (d. 1101), count of Sicily from 1072, was born in Normandy, the last son of the second marriage of Tancred of Hauteville. He was thus the youngest brother of Robert (*q.v.*) Guiscard, whom he went to join in southern Italy in 1057. By courageous efforts he did much to help Robert's conquest of Calabria from the Byzantines; and when this was complete (1060) the brothers turned their attention to Sicily, where discord between various Muslim rulers offered them an opportunity to combine their own interests with the service of Catholic Christianity.

Having taken Messina in 1061, Robert went back to his duchy of Apulia to fight the Byzantines. Left in command in Sicily, Roger was in no hurry to pursue the enterprise, as his army was inadequate against the strong positions of the Muslims, who moreover were being reinforced from Tunis. Even so, he won victories at Cerami (1063) and at Misilmeri (1068) over superior forces before help sent by Robert enabled him to capture Palermo in 1072. Meanwhile he had no intention of being merely Robert's tool: to assert himself, he more than once went into armed rebellion against Robert. The latter met his demands on each occasion: in 1062 he agreed to a regime of condominium in Calabria, every city and castle there being owned jointly by the brothers; and in 1072 he granted Roger the title of count of Calabria and Sicily, though he reserved to himself Palermo, half of Messina, and half of Val Demone, as well as the feudal suzerainty over the countship.

After Robert's death (1085), Roger took Syracuse in 1086 and completed the conquest of Sicily by the capture of Noto in 1091 (a few months after receiving the submission of Malta and Gozo). When the feeble Duke Roger of Apulia, Robert's son, was faced by rebellion, Roger of Sicily gave him decisive support, in return for which the duke renounced to him the Sicilian territories formerly reserved by Robert. The foremost ruler in Norman Italy, Roger assumed the title grand count of Sicily and Calabria.

To establish Catholicism in Sicily, Roger himself created ecclesi-

astical dioceses. The bishops whom he appointed came nearly all from north of the Alps. Pope Urban II in 1099 nominated him apostolic legate in Sicily, thus recognizing his control over the church there. Yet Roger was wholly tolerant toward his Muslim and Greek Orthodox subjects. The Muslims in the cities formed an autonomous community and continued to prosper as manufacturers and as merchants; and the main bulk of Roger's infantry was recruited from the Muslim serfs of the countryside.

Roger died on June 22, 1101, and was buried in the Abbey of La Trinità, at Mileto in Calabria, which he had founded.

BIBLIOGRAPHY.—E. Caspar, *Roger II und die Gründung der normannisch-sicilischen Monarchie* (1904); F. Chalandon, *Histoire de la domination normande en Italie et en Sicile,* 2 vol. (1907); E. Pontieri, *Tra i Normanni nell'Italia meridionale,* 2nd ed. (1964). (E. Po.)

ROGER II (1095–1154), king of Sicily from 1130, was a son of Count Roger I (*q.v.*) by his third wife, Adelaide. His father died in 1101, his elder brother Simon in 1105, leaving the countship of Sicily and Calabria to the child Roger. His mother was regent for him till 1112, but went to marry Baldwin I of Jerusalem in 1113.

Roger, who combined a keenly realistic intelligence with the typically Norman spirit of adventure, inherited his predecessors' idea of Sicily as the potential nucleus of a great Mediterranean empire. His first expedition against Mahdia, the stronghold of the Zirids of Tunisia, was unsuccessful (1123), and for some years afterward he was preoccupied with the Italian mainland. When William, duke of Apulia, died childless (1127), Roger, as William's first cousin once removed, persuaded the people of Salerno, capital of the duchy, to cede their city to him, and had himself crowned duke there. Since this destroyed the balance which the papacy had contrived to maintain between the Norman states in southern Italy, Pope Honorius II mustered a league of cities and barons in rebellion against Roger; but Roger defeated the Pope's forces and obtained investiture as duke from him (Aug. 23, 1128).

Honorius II's death (1130) was followed by a schism of the papacy. Roger supported the antipope Anacletus II against Innocent II. By a bull signed at Avellino on Sept. 27, 1130, Anacletus invested Roger with the kingdom of Sicily, Calabria, and Apulia, the principality of Capua, the honour (fief) of Naples, and the protectorate over Benevento, in return for acknowledgment of the Holy See's feudal suzerainty and payment of annual tribute. On Christmas Day, 1130, at Palermo, Roger was crowned king of a kingdom, most of which was yet to be won.

Pope Innocent II, the Holy Roman emperor Lothair II, the Byzantine emperor John II Comnenus, the French king Louis VI, the Venetians, and the Pisans formed a coalition to check Roger's growing power, while within the new kingdom cities and feudatories, in particular Robert of Capua, rose against him. Nine years of warfare ensued, but Lothair's march across the Abruzzi to Bari and the Pisans' naval attack on Salerno both came to nothing (1137), and Roger was finally free to concentrate his efforts against Innocent II, whom Anacletus II's death (1138) had made more dangerous. Taken captive (July 22, 1139), Innocent made peace and recognized Roger as king by the Treaty of Mignano (July 25). Roger then made his kingdom a reality by subduing Capua and Naples. (*See* also NAPLES, KINGDOM OF; SICILY: *History.*)

Meanwhile Roger had not forgotten his designs on North Africa and on the Aegean coastlands. His admiral, George of Antioch, built him a magnificent fleet, and between 1135 and 1148 the island of Djerba and places on the Tunisian and Tripolitanian coasts were seized. Expeditions into Byzantine territory led to the conquest of Corfu and threatened Constantinople, though Venice and the German king Conrad III gave help to the Byzantines.

Though he organized his state feudally, Roger's royal authority was extraordinarily effective. His augmentation of his prerogatives as apostolic legate led to conflict with the Holy See. In public administration his supreme organ, the Magna Curia, exercised an all-pervasive influence down to the lowest levels through a well-articulated bureaucracy. All the ethnic elements of the kingdom were admitted to a role in the administration, for which the only qualifications required were efficiency and loyalty: Arabs were active in the financial offices, Italians and Greeks in the judiciary, Frenchmen and Normans in the feudal structure. An enlightened eclectic, Roger put his kingdom on the road to racial and cultural integration. His concern for the welfare of the community as a whole, overriding personal privilege and even his own royal advantage, was exceptional among contemporary rulers. He was also a generous patron of science, literature, and art, still commemorated by Palermo's examples of Islamic, Byzantine, Romanesque, and Composite architecture. He died in Palermo on Feb. 26, 1154, and was entombed in the cathedral.

ROGER OF WENDOVER (d. 1236), English chronicler, whose *Flores historiarum* is the fullest narrative source for the reign of Henry III, was probably a native of Wendover, Buckinghamshire. He became a monk of St. Albans, Hertfordshire, and later prior of the cell at Belvoir, Leicestershire, but was found guilty of wasting the endowments and deposed. His latter years were passed at St. Albans where he died on May 6, 1236. He was the first of the important chroniclers who worked in the scriptorium there. The *Flores historiarum,* which begins at the Creation and extends to 1235, becomes of fully original value from the beginning of Henry III's reign and contains the sinister, savage portrait of King John, later exaggerated by Matthew Paris in his *Chronica majora,* which incorporated and continued the *Flores historiarum.*

The *Flores historiarum* survives in Douce Manuscript 207 (*c.* 1300; Bodleian Library, Oxford) and Cotton Manuscript Otho B v (*c.* 1350; British Museum, London). Matthew Paris' *Chronica majora* was edited by H. R. Luard, seven volumes, Rolls Series (1872–80). H. O. Coxe edited the *Flores,* 447 and after, five volumes, English Historical Society (1841–44), and H. G. Hewlett, 1154 and after, three volumes, Rolls Series (1886–89).

ROGERS, HENRY DARWIN (1808–1866), U.S. geologist and foremost structural geologist of his time, was born at Philadelphia, Aug. 1, 1808, one of four brothers, all of whom achieved fame as scientists. At 21 he became professor of chemistry and natural philosophy at Dickinson College, Carlisle, Pa. Three years later he went to Europe for advanced studies. In 1835 he became professor of geology and mineralogy in the University of Pennsylvania, and also undertook a geological survey of New Jersey. In 1836 he became state geologist of Pennsylvania. In 1842 he and his brother, WILLIAM BARTON ROGERS (1804–1882), state geologist of Virginia, jointly published their views on the Appalachian Mountains. Though their understanding of mountain-building processes was imperfect, in view of concepts then current, their observations of geologic features peculiarly distinctive of the Appalachians have stood the test of time remarkably well. H. D. Rogers' investigations culminated in his final two-volume *Report on Pennsylvania* (1858), in which he included a general account of the geology of the United States and of the coalfields of North America and Great Britain. In 1857 Rogers became regius professor of natural history in the University of Glasgow, Scot., the first American to be so honoured. He died at Glasgow, May 29, 1866. (F. M. Fl.)

ROGERS, JOHN (*c.* 1500–1555), English Reformer, editor of Matthew's Bible and first Protestant martyr of Mary I's reign, was born at Aston, near Birmingham, and educated at Pembroke Hall, Cambridge (B.A., 1526). Six years later he was rector of Holy Trinity, Queenhithe, London, and in 1534 went to Antwerp as chaplain to the English merchants. There he met William Tyndale (*q.v.*), under whose influence he abandoned the Roman Catholic faith, and married an Antwerp lady. After Tyndale's death Rogers carried on with the English version of the Old Testament on which Tyndale had been working. He used it as far as II Chronicles, employing Miles Coverdale's translation (1535) for

the remainder and for the Apocrypha. Tyndale's New Testament had been published in 1526. The complete Bible was put out under the pseudonym of Thomas Matthew in 1537; it was printed in Antwerp and Richard Grafton bought the sheets and got permission to sell the edition (1,500 copies) in England. Rogers had little to do with the translation, but he contributed some valuable prefaces and notes. His work was largely used by those who prepared the Great Bible (1539), out of which in turn came the Bishop's Bible (1568) and the Authorized Version of 1611. (*See* BIBLE, TRANSLATIONS OF: *English.*)

After taking charge of a Protestant congregation in Wittenberg for several years, Rogers in 1548 returned to England, where he published a translation of Philipp Melanchthon's *Considerations of the Augsburg Interim.* In 1550 he was presented to the crown livings of St. Margaret Moyses and St. Sepulchre in London, and in 1551 was made a prebendary of St. Paul's Cathedral, where the dean and chapter soon appointed him divinity lecturer.

On the accession of Mary, Rogers preached at St. Paul's Cross commending the "true doctrine taught in King Edward's days" and warning his hearers against "pestilent Popery, idolatry, and superstition." Ten days later (Aug. 16, 1553), he was summoned before the council and told to stay within his own house. In January 1554 the bishop of London sent him to Newgate, where he was imprisoned for a year. On Jan. 22, 1555, Rogers, with ten others, was brought before the council in Southwark and examined. On the 28th and 29th he came before the commission appointed by Reginald Cardinal Pole and was sentenced to death for heretically denying the Christian character of the Roman Catholic Church and the real presence in the sacrament. He was burned on Feb. 4, 1555, at Smithfield.

See H. H. Hutson and H. R. Willoughby, *Decisive Data on Thomas Matthew Problems* (1938).

ROGERS, JOHN (1829–1904), U.S. sculptor, creator of a popular series of small groups illustrating literary, historical, and humorous subjects, the so-called "Rogers groups," was born in Salem, Mass., Oct. 30, 1829. He was largely self-taught although he did work for a brief time in the studio of the English sculptor Benjamin Spence in Rome. In 1859 he settled in New York. Eight thousand copies of his most popular group, "Coming to the Parson," were sold, and it is estimated that the total number of groups sold came to about 80,000. Rogers also made portrait busts; the equestrian statue of Gen. John F. Reynolds in Philadelphia, Pa., and the statue of Pres. Abraham Lincoln in Manchester, N.H. The small plaster "Rogers groups" were reproduced from bronze master models. A large collection of these bronzes was acquired by the New York Historical Society, New York City, which also has the Rogers family portraits and papers. He died in New Canaan, Conn., July 26, 1904. (A. T. G.)

ROGERS, SAMUEL (1763–1855), English poet, best remembered for the witty conversation at his breakfast and dinner parties, and as a friend of greater poets, was born at Newington Green, near London, on July 30, 1763. His father had set up as a banker with money derived from a glass factory, and his mother came of a Dissenting family notable for its piety. When he was 17 he published an essay in the *Gentleman's Magazine.* His first volume of poetry attracted little attention, but the success of *The Pleasures of Memory* (1792) made him a celebrity. He had little originality or imaginative power, but he often succeeded in concealing this by the easy harmony of his verse and the carefulness of his expression. On his father's death (1793) he became principal owner of the banking firm. In 1803 he moved to 22, St. James's Place, London, and there he remained for the next half-century, a leading figure in London society. He was an amusing, though unkind, conversationalist—he claimed that his voice was so weak that no one would have listened to him if he had not said unkind things—and he used his knowledge and wealth to form a collection of paintings and other *objets d'art* that made his apartments a Mecca for anyone ambitious of being considered a man of taste. His breakfast and dinner parties were famous for the witty conversation of the carefully selected guests, recorded by Alexander Dyce and published as *Recollections of the Table-Talk of Samuel Rogers* (1856; edited by M. Bishop, 1952). In spite of his sharp tongue he was a kindly man, and many writers had reason to think of him with gratitude: he reconciled Thomas Moore with Francis Jeffrey and with Byron, aided the dramatist Sheridan during the last months of his life, and did a great deal to secure a pension for Henry Cary, the translator of Dante. Most important of all, it was he who secured for Wordsworth the position of distributor of stamps for Westmorland (1813).

Rogers once wrote that his "constant wish" in life had been "to live with those who were eminent." In this he was extraordinarily successful, and the length of his life gave him unusual opportunities. As a boy he once set out to visit Dr. Johnson, but modesty prevented him from knocking on the great man's door. It is remarkable to reflect that that boy lived on until the year which saw the publication of Anthony Trollope's *The Warden* and Robert Browning's *Men and Women.* His friends included Charles James Fox, Edmund Burke, Richard Porson, Sir Walter Scott, Byron (who had an exaggeratedly high opinion of his merits as a poet), and the duke of Wellington. Having attained eminence during a lean period for poetry and lived through a period of genius, he naturally became timid about publication, but two of his poems which deserve mention are *Human Life* (1819) and *Italy,* which attracted little attention on its first publication in 1822 but scored a marked success when it reappeared with illustrations by J. M. W. Turner and Thomas Stothard eight years later. On the death of Wordsworth in 1850 Rogers refused the laureateship. His poetry strikes the modern reader as Regency album verse, but Rogers remains important because of the greater men with whom he associated. He died on Dec. 18, 1855.

ROGERS, WILL (WILLIAM PENN ADAIR ROGERS) (1879–1935), U.S. humorist and motion-picture actor, writer of a newspaper column famous for its homespun humour and for its good-natured but extremely sharp criticism of contemporary men and affairs, was born Nov. 4, 1879, at Oologah, Indian Territory (now Oklahoma). Utilizing the rope twirling and lassoing he learned on his father's ranch, he began a career as a rope-throwing cowboy in steer-roping contests, Wild West shows, and vaudeville. In 1915, appearing in Ziegfeld's *Midnight Frolic* in New York, he introduced a humorous political commentary into his act. This developed into a newspaper column, syndicated weekly in 1922 and daily in 1926. Rogers also wrote a series of books in a similar vein, including *The Cowboy Philosopher on Prohibition* (1919), *Illiterate Digest* (1924), and *There's Not a Bathing Suit in Russia* (1927). Rogers was equally successful as a motion-picture actor. His films included *A Connecticut Yankee* (1931), *State Fair* (1933), and *David Harum* (1934). With the pilot Wiley Post he was killed in a plane crash in Alaska on Aug. 15, 1935. (M. S. By.)

ROGERS, WILLIAM (1819–1896), English educational reformer, known as "Hang-theology Rogers" because of his proposals that doctrinal training be left to parents and clergy, was born in London on Nov. 24, 1819, and died there on Jan. 19, 1896. He was ordained in 1843, and in 1845 was appointed to the curacy of St. Thomas', Charterhouse, where he remained for 18 years, throwing himself passionately into the work of education of his poor and often criminal parishioners. He began by establishing a school for ragamuffins in a blacksmith's abandoned shed, and he gradually extended its scope until schools were provided throughout the parish. In 1863 he became rector of St. Botolph's, Bishopsgate, and at Bishopsgate Rogers tackled the problem of intermediate, or higher elementary, education. He advocated secular education and to the cry against "godless education" replied, "Hang theology; let us begin," earning his lasting nickname. Rogers reconstructed Edward Alleyn's charity at Dulwich and founded the Bishopsgate Institute.

ROGET, PETER MARK (1779–1869), English physician and philologist, remembered for his *Thesaurus of English Words and Phrases,* a comprehensive classified list of synonyms or verbal equivalents which is popularly supposed, in its author's own phrase,

"to facilitate the expression of ideas and to assist in literary composition." This work, published in 1852 and since then seldom, if ever, out of print, was the product of Roget's retirement from active medical practice. Though begun in his 61st and finished in his 73rd year, the *Thesaurus* was based on a methodical system of verbal classification which he had set out for his own use in a manuscript notebook in 1805.

The son of John Roget (d. 1783), a Genevan refugee who was pastor of the French Protestant church in Threadneedle Street, London, Roget was born in Soho, London, on Jan. 18, 1779. His mother, from whom he is reputed to have inherited his systematizing tendency, was a sister of Sir Samuel Romilly, the advocate and law reformer. Roget studied medicine at Edinburgh, and in 1805 was appointed physician to the infirmary at Manchester, where he helped to found the medical school. From 1808 to 1840 he practised in London, also lecturing and writing on many scientific topics. In 1815 his invention of a slide rule brought him a fellowship of the Royal Society, of which, in 1827, he became secretary. He also played a part in the founding of London University.

For some time before his death (at West Malvern, Worcestershire, on Sept. 12, 1869), Roget had been working on an enlarged edition of the *Thesaurus*, which was completed and published by his son in 1879. Later editions were revised by Roget's grandson; and editions in Everyman's Library (1952), as a paperback (1953), and in dictionary form (1961), attested the work's continued popularity. (OL. S.)

ROGIER, CHARLES LATOUR (1800–1885), one of the architects of Belgian independence and the foremost Liberal statesman in the first four decades of the new kingdom. He was born at Saint-Quentin, in northern France, on Aug. 17, 1800, of Belgian immigrants. His family later moved to Liège, and he began practice as a barrister. In 1824 he was one of the founders of the journal *Mathieu Laensbergh* (afterward renamed *Le Politique*), which soon became known for its Belgian patriotism and its criticisms of the Dutch administration, Belgium being at that time part of the unitary kingdom of the Netherlands (*see* BELGIUM: *History*).

When insurrection broke out in Brussels in August 1830, Rogier mustered 150 Liégeois and marched with them to support it. Recognized at once as a leader of the revolutionary movement, he was chosen to be president of the administrative commission formed on Sept. 24. On Sept. 25 this commission was transformed into a provisional government, of which Rogier remained one of the principal members. Representing this government, he went in October to Antwerp, where the Dutch still held the citadel: he arranged the armistice there and reorganized the administration of the town.

Deputy for Liège in the National Congress, Rogier insisted on the proclamation of Belgian independence and on the establishment of a hereditary monarchy. When a regency for the vacant throne was inaugurated the provisional government resigned (Feb. 24, 1831). At first Rogier wanted the crown to be offered to the duc de Nemours (Louis Charles Philippe Raphaël d'Orléans), son of Louis Philippe, king of the French; but when Louis Philippe declined this offer for his son, Rogier transferred his vote to Leopold of Saxe-Coburg, who was elected king as Leopold I (*q.v.*).

After being governor of Antwerp from June 1831, Rogier became minister of the interior on Oct. 20, 1832. In this capacity, he carried, against strong opposition, the law for the construction of railways; but disagreement within the cabinet led to his resignation on Aug. 1, 1834, whereupon he resumed the governorship of Antwerp. For a year from April 1840 he was minister of public works, education, and the fine arts.

The growing antagonism between the Catholic or Clerical and the Liberal parties in Belgium kept Rogier out of office from 1841 to 1847, when on Aug. 12 he formed a Liberal government. In this government he was not only prime minister but also minister of the interior. His policy did much to save Belgium from the revolutionary convulsions which shook Europe in 1848. In the summer of 1852 he resigned, but was persuaded by the king to resume office till Oct. 31.

On Nov. 8, 1857, Rogier took office again as prime minister and minister of the interior. He exchanged the latter portfolio for that of foreign affairs in October 1861 and achieved a major international success in 1863, when his envoy Auguste Lambermont (*q.v.*) negotiated the agreement with the Netherlands freeing Antwerp's commerce from liability to tolls on the Scheldt River. On Dec. 30, 1867, he retired from office, being succeeded in January 1868 by his former minister of finance, H. J. W. Frère-Orban (*q.v.*).

Rogier was active in public affairs throughout the 1870s. He died, a nationally honoured figure, at Saint-Josse-ten-Noode, Brussels, on May 27, 1885.

See E. Discailles, *Charles Rogier*, 4 vol. (1893–95).

ROHAN, a family of great distinction in French history. Of Breton origin, it is said to be descended from a junior member of the original sovereign House of Brittany, and its later claims to princely rank in France were based on this supposition. Its traditional motto, *Roi ne puis, duc ne daigne, Rohan suis* ("King I cannot be, duke I disdain, Rohan I am"), fell out of use as Rohans acquired duchies.

Alain I, a younger son of a viscount of Porhoët, is recorded as having his seat at Rohan in the 1120s. His descendants, on whose viscounty of Rohan the lordship of Guéméné (Guémenée, Guimené, etc.) was feudally dependent, increased their possessions by marrying heiresses: by the end of the Middle Ages Corlay, Rochefort, Léon, Porhoët, and Montauban (-en-Bretagne) were in their hands. By 1470, three of their wives had come from the sovereign dynasty of Brittany, one from that of Navarre.

The direct male line of the viscounts died out with Jacques de Rohan (1478–1527), and his brother Charles (1480–1540), bishop of Quimper. Their sisters Anne (d. 1529) and Marie (d. *c.* 1542) had been married respectively to Pierre II de Rohan-Gié, seigneur de Frontenay, and Louis IV de Rohan-Guéméné, both of whom were descendants of Charles I, seigneur de Guéméné (d. 1438), a younger son of the viscount Jean I (d. 1396). Louis IV's branch of the family was genealogically senior, but Pierre II's branch acquired the preponderant part of the viscounts' inheritance.

Rohan-Gié and Rohan-Chabot.—Charles I de Guéméné's grandson Pierre I de Rohan, seigneur de Gié (1451–1513), was appointed a marshal of France in 1475. He campaigned in the Low Countries and in Italy and became the rival of the cardinal Georges d'Amboise (*q.v.*) in King Louis XII's government. He was married, in 1503, to Marguerite d'Armagnac, through whom he advanced claims to the title of duc de Nemours. When Louis XII fell ill, however, in 1503, the marshal de Gié took measures to prevent the queen of France, Anne (*q.v.*) of Brittany, from retiring to Brittany, lest she should separate Brittany from France if Louis XII died. Anne and the cardinal d'Amboise, on Louis XII's recovery, misrepresented the marshal's actions as criminal. He was brought to trial (1504–06). Acquitted of the graver charges, he was found guilty of lesser ones and sentenced to five years' exile from court. He never returned to public life.

Pierre II, the marshal's son, was the father of René I (d. 1552), who in 1534 married Isabelle d'Albret, daughter of Catherine de Foix-Grailly, queen of Navarre (*see* ALBRET). Their son René II (1550–86) was a military leader of the Huguenots in the Wars of Religion and the husband of Catherine de Parthenay, heiress of the lordship of Soubise, who herself, as vicomtesse de Rohan, was a heroine of the Huguenots till her death (1630). René II's sister Françoise, demoiselle de La Garnache, had a child by Jacques de Savoie, duc de Nemours, but he broke his promise to marry her: in the consequent outcry, the Huguenot princes took her side, while the House of Guise took his. She was finally compensated in 1579 with the title of duchesse de Loudun for her lifetime.

René II's son Henry (1579–1638) was created duc de Rohan and a peer of France in 1603. He was married to Marguerite de Béthune, daughter of the duc de Sully, in 1605. Having led the Huguenots in revolt against the government of Marie de Médicis in 1615–16, he became their foremost general in the civil wars of the 1620s, campaigning with considerable success in Languedoc. Having twice made shortlived treaties with King Louis XIII's government (1623 and 1626), he took up arms again in 1627, during the War of La Rochelle, and fought on in Languedoc till the

Peace of Alais (1629). After a long stay in Venice, he returned to France in 1635 and was given command of the army sent across Switzerland to intervene against the Habsburgs' forces in the Valtellina. Militarily victorious, he failed to win the population to a pro-French policy and was driven out in 1637. After a stay in Geneva, he joined Bernhard (*q.v.*) of Saxe-Weimar in Germany. Mortally wounded with Bernhard's troops in battle at Rheinfelden, he died on April 13, 1638. He had published a masterpiece of military theory, *Le Parfaict Capitaine* (1636; Eng. trans., *The Complete Captain*, 1640), and left several autobiographical writings. His brother Benjamin, seigneur de Soubise (1583–1642) was also prominent as a Huguenot rebel in the 1620s. He led expeditions from England against the west coast of France and died in London a respected exile. His sister Anne de Rohan (1584–1646) was notable for a few poems.

In 1645 the first duc's daughter Marguerite (1617–84) took as her husband a poor nobleman, Henry Chabot (1616–55). The French crown erected a new peerage-duchy of Rohan for him, with the proviso that his children should be Catholics; and it was stipulated that they should bear the name and arms of Rohan. The proviso on religion, together with Chabot's poverty, infuriated the dowager duchesse, Marguerite de Béthune, who thereupon produced from obscurity a young man, Tancrède, and implausibly put him forward as her late husband's son and heir; but Tancrède was killed in 1649, fighting for the Fronde. The right of Chabot's descendants to the name of Rohan was confirmed by Louis XIV in 1704, after an attempt by the other Rohans to deprive them of it. Their title of duc de Rohan (-Chabot) survives in the 20th century.

Rohan-Guéméné.—Louis II, seigneur de Guéméné (d. 1508), was the marshal de Gié's elder brother. His grandson Louis IV (d. 1527) inherited Montbazon, in Touraine, through his mother. Louis IV's grandson Louis VI (d. 1611) obtained the title of prince de Guéméné, but this merely decorated his fief, without conferring princely rank on the House of Rohan (*see* PRINCE for the distinctions involved). His son Louis VII (d. 1589) was created duc de Montbazon in 1588. This peerage was recreated in 1594 for his brother Hercule (1568–1654). Hercule was the father, by his first marriage, of the celebrated duchesse de Chevreuse (*q.v.*) and was the husband, by his second, of that duchesse de Montbazon (Marie d'Avaugour; d. 1657) who quarreled with the duchesse de Longueville (*q.v.*) and was famous during the Fronde as the mistress of the duc de Beaufort (*q.v.*). Hercule's son Louis VIII (1598–1667), married his first cousin Anne de Rohan (d. 1685), who, as the princesse de Guéméné till her husband became duc de Montbazon in 1654, was also active in the intrigues of the Fronde. It was she who began gradually to secure for the House of Rohan privileges analogous to those of foreign princes.

Anne de Rohan-Chabot (d. 1709), Henry Chabot's daughter, was married in 1663 to Hercule's son by his second marriage, François de Rohan-Montbazon (1631–1712), to whom the title of prince de Soubise was granted in 1667. This princesse de Soubise exploited her influence as one of King Louis XIV's mistresses to advance her husband's family, with such success that the ensuing decades of its princely aggrandizement became known to the envious French nobility as "the Age of the Rohans." Her son Hercule Mériadec (1669–1749) was created duc de Rohan-Rohan in 1714. Another son of hers, Armand Gaston Maximilien (1674–1749) became bishop of Strasbourg in 1704 and cardinal de Rohan in 1712. The latter's grandnephew, Armand (1717–56) became cardinal de Soubise in 1747 and bishop of Strasbourg in 1749. This pair must not be confused with their successors, Louis Constantin (1697–1779), bishop of Strasbourg from 1756 and cardinal from 1761, and Louis René Édouard (1734–1803), cardinal de Rohan from 1778 and bishop of Strasbourg from 1779 to 1801, who both were descendants of Louis VIII. (For Louis René Édouard *see* DIAMOND NECKLACE, AFFAIR OF THE.)

Louis VIII's younger son, Louis, chevalier de Rohan, led a dissipated life and finally committed high treason for money by plotting to deliver Quillebeuf to the Dutch. For this he was beheaded in Paris in 1674.

Charles de Rohan, prince de Soubise (1715–87), a great-grandson of the first prince, fought in the Seven Years' War. Better at flattering King Louis XV's mistresses than at soldiering, he was defeated by Frederick the Great in the Battle of Rossbach (1757) but had some success later, for which he was appointed a marshal of France (1758). He also became a minister of state.

Jules Hercule Mériadec (1726–88), duc de Montbazon, of the fourth generation from Louis VIII, married Louise Henriette de La Tour d'Auvergne; and their son Henri Louis (1745–1801) married Victoire, daughter of the marshal de Soubise. Thus the latter's son Charles Alain Gabriel, duc de Montbazon (1714–1836), inherited on the one hand the title to Bouillon (*q.v.*), on the other the Soubise or Rohan-Rohan titles. In 1808, moreover, the House of Rohan (-Guéméné) had been granted Austrian domicile and the Austrian title of prince (*Fürst*). In 1846, the accumulated titles passed to the branch of Rohan-Rochefort-Montauban, descendants of Jules Hercule Méridadec's uncle Charles (1693–1766).

(J. G. R.-S.)

RÖHM, ERNST (1887–1934), German army officer, and chief organizer of Hitler's Nazi *Sturmabteilungen* (storm troops) after World War I, was born in Munich on Nov. 28, 1887, the son of a railway official. He joined the army in 1906 and during World War I was wounded three times; being noted for gallantry he rose to the rank of major. After the war he remained on the staff of the army district command in Munich until he resigned his commission on Sept. 26, 1923. He was an active leader of freebooting soldiers, and took part in founding, before Hitler, the National Socialist German Workers' Party. He helped Hitler to win the support of the army in Bavaria, and provided him with the services of his own strong-arm squads. In October 1921 these became the *Sturmabteilungen* (the brown-shirted SA). Röhm took a prominent part in the Munich *Putsch* on Nov. 8–9, 1923, was arrested and sentenced to a short term of imprisonment but was discharged in April 1924. Hitler wanted the SA to remain subordinate to the party, while Röhm wanted it to be on equal terms with the party, and eventually either to absorb or to replace the regular *Wehrmacht*.

As a result of this disagreement Röhm resigned the leadership of the SA in 1925 and went as an army instructor to Bolivia. At the end of 1930 Hitler persuaded him to return to reorganize the SA which, with the growth of unemployment, was seriously out of hand. For the next three years Röhm provided an organized but disreputable body of men to give the Nazis force. Röhm wanted to stage a *coup d'état* in 1932, but was restrained by Hitler. When Hitler became chancellor Röhm deplored his delay in continuing the revolution. Hitler was as yet unprepared to challenge the army. For a time he compromised, and in December 1933 brought Röhm into his cabinet. He then decided to reduce the SA to the status of a subordinate body unable to rival his own power or to make trouble with the *Wehrmacht*. To this end he carried out the purge of June 30, 1934, on the pretext that Röhm and the SA were preparing a *Putsch*. The evidence hardly supported this charge. Unsuspecting Röhm was taken by Hitler personally from his hotel at Bad Wiessee, outside Munich, and was shot without trial at Munich-Stadelheim. Röhm's memoirs were published under the title *Die Geschichte eines Hochverräter* (2nd ed., 1934).

(W. KP.)

ROHTAK, a town and district in the Ambala division of Punjab, India. The town, headquarters of the district, lies 44 mi. (71 km.) NW of Delhi by rail. Pop. (1961) 88,193. It is of great antiquity and is said to have been founded by Raja Rohtas of the Ponwar Rajputs. Some fine pieces of sculpture of the Buddhist period have been recovered from Khokra Kot, an ancient mound near the town. The old town of Rohtak was surrounded by a wall with 11 gates, the remains of which can still be seen. There are five colleges affiliated to Panjab University. The town is a flourishing grain centre and has a large sugar mill. Viewed from the sand hills to the south, with its white Dini mosque (1140) in the centre and fort to the east, Rohtak is picturesque.

ROHTAK DISTRICT, situated in the Jumna-Sutlej divide, is mostly a level plain, with a few hills—outliers of the Aravalli Range—and sand dunes in the south, and an area of inland drainage in the southeast which turns marshy during the rainy season. Area 2,330 sq.mi. (6,035 sq.km.). Pop. (1961) 1,420,391. Annual

rainfall averages about 19 in., mostly falling in July–September. More than three-quarters of the total area is under cultivation, and nearly half of this is irrigated by the Rohtak and the Butana branches of the Western Jumna Canal and wells, the remainder depending upon uncertain rainfall. The principal crops are wheat, millets, gram, barley, sugarcane, and cotton. The district's towns and local trading centres include Sonepat (pop. [1961] 45,882), Bahadurgarh (14,982), and Jhajjar (14,234). (O. P. B.)

ROJAS, AGUSTÍN DE (1572–*c.* 1635), Spanish actor and author whose most important work, *El viaje entretenido* (1603), gives a valuable account of the Spanish theatre in the 16th century and the life of its actors. Born at Madrid in 1572, at 14 he ran away to Seville, and led an adventurous life as a soldier, serving in France, where he was taken prisoner. He returned to Spain through an exchange of prisoners, and eventually became an actor in various touring companies. After his marriage (at Valladolid in 1603), he settled down as a public functionary, being clerk to the council of Zamora in 1607 and public notary to the episcopal audience there in 1611. The precise date and place of his death are not known.

El viaje entretenido, an autobiographical novel in dialogue, of a picaresque type, contains much detailed and lively information about the life of a traveling actor. Among Rojas' other works are the play *El natural desdichado,* and 40 *loas* or laudatory dramatic prologues, which, in their varied treatment of their subject matter, provided a model for later writers in the genre.

See G. I. Dale, article on *El natural Desdichado,* in the *Hispanic Review,* ii (1934); H. A. Rennert, *The Spanish Stage in the Time of Lope de Vega* (1909; new ed. 1964). (L. J. Cl.)

ROJAS PINILLA, GUSTAVO (1900–), former dictator of Colombia, was born March 12, 1900, at Tunja. A professional soldier, he was graduated from the Colombian Military Academy in 1920. While on inactive status (1924–1933), he earned a civil engineering degree in the United States. After 1933 he rose rapidly in the army to the rank of lieutenant general, represented Colombia at a number of international conferences, and was a member of the Inter-American Defense Board (1951–1952). Rojas' political interests date from his suppression of the April 1948 riots in Cali. Increasingly identified with the Conservative opposition to the administration of Pres. Laureano Gómez, Rojas seized control of the government on June 13, 1953, after Gómez had resolved to remove him as commander of the armed forces. Rojas promised peace, justice, and liberty to end violence in rural areas. However, his corrupt authoritarian administration converted nationwide popularity into united national hostility. On May 10, 1957, he appointed a military junta to govern in his place and left the country. Impeached after returning in October 1958, he lost his civil rights in April 1959. Nevertheless, he reentered politics and in 1962 won 2.5% of the votes cast for president. (R. L. Ge.)

ROKITANSKY, KARL, Freiherr von (1804–1878), Austrian pioneer in the science of pathology, was born at Königgrätz, Bohemia, on Feb. 19, 1804. He studied medicine at Prague and at Vienna, where he was appointed professor extraordinary of pathological anatomy in 1834. He became president of the Vienna Academy of Sciences in 1869 and was named freiherr in 1874. He was active in the Austrian legislature, becoming speaker of the House. He died in Vienna, July 23, 1878.

Rokitansky performed more than 30,000 autopsies. The differentiation of lobar and lobular pneumonia is based on his findings, as are the pathology of acute dilatation of the stomach, acute yellow atrophy of the liver (Rokitansky's disease), and the pulmonary complications of typhoid fever. He elucidated the micropathology of emphysema, a lung disease, and is credited with the first description of spondylolisthesis, or dissolution of a vertebra. His *Handbuch der pathologischen Anatomie* (1842–46, English translation 1849–52) was an important work.

ROKYCANA, JAN (Czech Jan z Rokycan) (*c.* 1390–1471), third of the chief religious leaders of the Hussites (*q.v.*), was the son of a poor smith of Rokycany near Plzen, in Bohemia. He went to Prague probably in 1410, becoming there the close assistant of Jakoubek (Jacobellus) of Stribro and finally his successor as organizer of the Hussite Church. Like Jan (John) Huss a powerful preacher, Rokycana became in 1423 minister of the largest church in Prague and soon chief of the clergy of the Prague party, as well as, from 1432, of that of the "Orphans" (moderate Taborites). In the peace negotiations with the Council of Basel he was in 1433 speaker for the large Hussite delegation. In 1435 he was elected by the Diet to the archbishopric of the Hussite Church and in 1436 signed in its name the peace treaty with the council. The following year the emperor Sigismund drove Rokycana out of Prague, and the ensuing reaction prevented his return until 1448. After that the leader of the undaunted Hussites, George of Podebrady, helped him to achieve general recognition.

George's election as king in 1458 meant immense success for Rokycana and the Hussites, but for the papacy it was a challenge to war. (*See* Bohemia.) In 1462 Pius II revoked the peace of 1436, and his successor declared a crusade in 1467 against the Hussites. Nonetheless both Rokycana and the king died in 1471 (Rokycana in Prague on Feb. 22; George a month later) unconquered and in the justified belief that their work was saved permanently; theirs was the first great national church which the papacy was unable to conquer, and within 50 years it became the ideal of the churches of the Reformation.

See F. M. Bartoš, *Literární činnost Mistra Jana Rokycany . . .* (1928). (F. M. Ba.)

ROLAND (DE LA PLATIÈRE), JEAN MARIE (1734–1793), French statesman of the Revolution, an author and industrial scientist who, largely through his wife's ambition and influence, was minister of the interiòr for two short periods in the years 1792 to 1793. He was born at Thizy, near Roanne in the Lyonnais, on Feb. 18, 1734.

On Feb. 4, 1780, Roland married Marie Jeanne (Manon) Phlipon (1754–93). Clear-headed and forceful, she exercised a commanding influence over him. In 1789 both the Rolands rapturously welcomed the Revolution. During a business visit to Paris (February–September 1791) Roland regularly attended the Jacobin Club and became closely connected with the future Girondins (*q.v.*). Meanwhile his wife's intense patriotism, intelligence, and charm took revolutionary society by storm. The couple moved permanently to Paris in December 1791 and on March 23, 1792, Roland, thanks to his friendship with Brissot, was appointed minister of the interior in a government formed under Girondin influence. He proved a good administrator, but when Louis XVI vetoed decrees to establish a camp of national guards outside Paris and to deport nonjuring clergy, Roland, in a letter drafted by his wife, called upon the king (June 10, 1792) to give way. Louis therefore dismissed Roland and other Girondin ministers on June 13. However, in the provisional government which was appointed after the attack on the Tuileries (Aug. 10, 1792; *see* France: *History*) and the overthrow of the monarchy, Roland was again minister of the interior. His wife now directed his work even more closely, making him the instrument of her opposition to Robespierre and Danton. Meanwhile Roland took an open part in the struggle between the Girondins and the Montagnards (the Mountain). His neglect to have the king's private papers, found in the Tuileries on Nov. 20, inventoried before witnesses, inevitably caused him to be accused of favouring the king. He resigned on Jan. 23, 1793, two days after Louis' execution.

At the outbreak (May 31) of the Paris insurrection which led to the fall of the Girondins, Mme Roland was arrested. Imprisoned in the Conciergerie, she wrote her memoirs, *Appel à l'impartiale postérité.* She was guillotined on Nov. 8, 1793. When Roland, who had escaped, heard of her death he killed himself at Bourg-Beaudouin, near Rouen, on Nov. 15.

See the numerous works on Mme Roland, notably M. Clemenceau Jacquemaire, *Life of Madame Roland,* Eng. trans. by L. Vail (1930). (A. So.)

ROLAND, CHANSON DE, a 4,000-line Old French epic, the subject being set in the context of Charlemagne's wars against the Saracens; in its extant form it dates from *c.* 1100. It is probably the oldest and certainly the finest of the *chansons de geste* (*q.v.*), and ranks as one of the great masterpieces of literature. Against a background which in many respects epitomizes the spirit

of the First Crusade (*see* CRUSADES), its Norman-sounding author, Turold (if, as seems probable, the explicit of the oldest manuscript [*c.* 1130–40?] in the Bodleian Library, Oxford, is to be interpreted as comprising the author's signature), tells a heroic tale that has made the name Roncevaux (*Roncesvalles;* the scene of the battle between the French and the Saracens) as immortal as that of Thermopylae, and Roland, its hero, the paragon of the unyielding warrior, victorious in defeat. But, much more, Turold has placed in the foreground the human conflict between Roland and Oliver which, as well as illustrating the contrast between *fortitudo et sapientia* (valour and wisdom), is also a conflict between divergent conceptions of feudal loyalty and honour: Roland, heroic and noble, but his judgment clouded by his foolhardy insistence on, and preoccupation with, personal honour and renown; Oliver, no less heroic, but perceiving when the dictates of prudence must, in the common weal, prevail; Ganelon, the traitor, no less noble and of great courage, loyal to the emperor according to his own lights, but bent only on his feud against Roland.

The Story of the "Chanson."—After conquering all Spain save Saragossa alone, Charlemagne, about to return to France, accepts overtures from the Saracen king Marsilion, despite the opposition of his nephew Roland, and sends Ganelon, Roland's stepfather, to Saragossa to negotiate peace terms. Ganelon, incensed against Roland, who had proposed him for the perilous task, conspires with the pagans to achieve the destruction of his stepson, and on his return ensures that the emperor, despite his misgivings, appoints Roland to command the rear-guard. Perceiving the overwhelming Saracen hordes, Oliver, Roland's companion in arms, counsels prudence in the face of the battle-eager jubilation of Roland, urging him to sound his horn to recall Charlemagne. But on Roland's proud refusal, the hopeless battle of Roncevaux is joined, and soon the French, despite the massacre they inflict, are reduced to a handful. Then, in a brief and poignant scene of great beauty and dramatic power, it is Oliver who, echoing Roland's earlier words, rejects his companion's proposal to sound his horn, for now it is too late. Archbishop Turpin settles the quarrel: let the horn be sounded, that Charlemagne may avenge their death. Roland at last blows a great blast on his horn that carries full 30 leagues to Charlemagne, but such is his effort that he bursts his temple. The battle continues, but, despite their prowesses, the French are overcome; Oliver, so blinded by his wounds that he strikes Roland in error, dies. Again Roland sounds his horn, but now weakly. The Saracens, hearing Charlemagne's trumpets in reply, flee after a final attempt to kill Roland. Turpin, after blessing the bodies of his comrades in arms, also dies. Roland, whom no pagan hand has been able to touch, is alone on the battlefield, and, knowing that death is close, attempts to destroy his sword Durendal by thrice striking it against a rock, lest it fall into enemy hands; but the blade, piercing the rock, remains unharmed, and Roland, composing himself to die in the attitude of contrition (*i.e.*, in prosternation), places it with his horn beneath him; in this position he dies, and the archangels receive his soul. As the emperor arrives on the battlefield, God halts the sun in its path that he may wreak his vengeance on the fleeing army.

The news of the Saracens' defeat has been carried by Marsilion to Saragossa, where the emir Baligant, earlier summoned to help repel Charlemagne, has assembled an even vaster army. Here follows a long account, which some critics, albeit on debatable grounds, hold to be apocryphal to the original poem, of the preparations of the two armies and the great battle they lead up to, ending in Baligant's defeat by Charlemagne and the capture of Saragossa. The emperor at last returns to Aix-la-Chapelle, on the way placing Roland's oliphant on the altar of Saint-Seurin-de-Bordeaux, and burying Roland, Oliver, and Turpin at Saint-Romain-de-Blaye. At Aix he announces the news of Roland's death to *la belle Aude*, Roland's promised bride and Oliver's sister, who on hearing it falls dead at Charlemagne's feet. Here begins the trial of Ganelon, charged with treason against the emperor; Ganelon's defense is that his action was directed not against Charles but against Roland whom he had defied in due form, and the barons recommend his acquittal. Thereupon, one of the emperor's knights, Thierry, argues otherwise, and a judicial combat is arranged between himself and Ganelon's champion, Pinabel, who is defeated. Ganelon is hanged and quartered, and thus is Charlemagne's justice achieved.

The Poem's Style.—The composition of the poem is firm and coherent, the style direct, sober, and, on occasion, stark, with no trace of ornamentation, and, despite the somewhat conventional ring of certain of the battle scenes, little visible literary device. The character drawing in particular is most striking, the most successful passages being those in which the author depicts, without comment or explanation, clashes of personality, among them those between Roland and Ganelon, Ganelon and Marsilion, Ganelon and Charlemagne, and, above all, Roland and Oliver. In these scenes, the underlying conflicting feudal concepts are vividly expressed in terms of human drama that has something of the inevitability of Greek tragedy. As opposed to the long account of the battle in which the emperor overcomes Baligant, and which somewhat suggests a set piece, the description of the earlier battle scenes is clearly subordinated to the roles of Roland and Oliver, and, to a lesser extent, of Turpin, leading in a crescendo of pathos to the death of each. This pathos is echoed in the lament pronounced by Charlemagne over the body of his nephew, and in the brief scene leading to the death of Aude. The language throughout is sure, and terse in its economy of expression. Although the *Roland* is one of the earliest monuments of French literature, and Turold its first great poet, there is nothing that does not suggest a well-established literary and linguistic medium.

Influence of the "Roland."—The success and development of the genre clearly owes much to Turold. Apart from more general considerations, many later authors appear to make a point of establishing a link between their narratives and the events of Roncevaux. Some go much farther and exploit and embellish the theme. Thus, earlier adventures are attributed to Roland and Oliver in the *chansons de geste Girart de Roussillon* (12th century), *Aspremont* (late 12th century), *Otinel* and *Anseïs de Carthage* (both *c.* 1200 ?) among others. Nor was the success of the *Roland* confined to northern France; a Provencal *Ronsasvals* and *Rollan a Saragossa* (? late 12th century) have survived. In Spain, in addition to the 13th-century fragment of *Roncesvalles*, the *Poema de mio Cid* (*see* SPANISH LITERATURE: *The Rise of Heroic Poetry*) itself owes much in conception, content, and form to the French *chansons de geste*, and an unmistakable echo of the Roland theme is found in the romance, *La Fuga del rey Marsín;* the discovery of the so-called *Nota emilianense*, a barbarous dog-Latin text inserted in a manuscript from the monastery of San Millán de la Cogolla, is evidence that French epic heroes, including Roland, Oliver, and Turpin as well as Guillaume, Bertrand, and Ogier, were early known in northern Spain, although the dating of this text as early as *c.* 1075 is not, on paleographic grounds, entirely conclusive. Italy offers not only the 13th- and 14th-century Franco-Italian manuscripts of the *Roland* itself, but also the Franco-Italian poems which exploit it—*Berte e Milone* (13th century), *Entree en Espagne* and *Prise de Pampelune* (14th century)—as well as Matteo Boiardo's *Orlando Innamorato* (publ. 1495) and Ariosto's *Orlando Furioso* (final version, 1532); in Sicily, the place names Capo d'Orlando and Capo d'Oliviere (Capo Calavà) testify to the early penetration of Rolandian themes to southern Italy, doubtless through the Normans. The German Konrad ("Pfaffe Konrad") translated an early version as the *Ruolantes Liet* (*c.* 1175), which was itself exploited by subsequent German writers, and the 13th-century compiler of the Norse *Karlamagnus-saga* translated a version of the *Roland* perhaps earlier than that of the Oxford manuscript (*see* ICELANDIC LITERATURE: *Romances*). In England, the decline of Anglo-Norman (the language of the earliest extant manuscript) led to a 15th-century adaptation, *Rowlandes Song*, and there exists a 14th-century Welsh prose narrative, *Campeu Charlyamen*, which includes an account of Roncevaux.

The *Historia Karoli Magni et Rotholandi* (*c.* 1150 ?)—the so-called *Pseudo-Turpin* (*see* TURPIN; CHARLEMAGNE LEGENDS), which constituted the fourth book of the *Liber sancti Jacobi*, composed in the interests of Santiago de Compostela (*q.v.*)—and the *Carmen de prodicione Guenonis* (*c.* 1200) are manifest deriva-

tives of the *Roland,* while from as early as the beginning of the 12th century allusions by Latin writers to events and characters of the *Roland* became frequent; Radulfus Tortarius (1063–1108?) in his *Epistola ad Bernardum* refers to Roland's sword; Raoul (Radulf) de Caen, writing between 1112 and 1118 (*Gesta Tancredi*) exclaims: *Rollandum dicas Oliveriumque renatos!* ("Roland and Oliver come to life!"); William of Malmesbury relates in a celebrated passage of his *Gesta regum Anglorum* (*c.* 1125) how a *jongleur* accompanied the Norman troops at Hastings declaiming of Roland; and Orderic Vitalis, in his *Historia ecclesiastica* (written *c.* 1123–31), couples Roland with Achilles.

The earliest examples of the impact of the Rolandian theme on medieval artists can be seen in the representation of scenes from the *Chanson* in the 13th-century Charlemagne window at Chartres cathedral, which shows Roland alone on the battlefield, sounding the horn and striking the rock with his sword, and also, in other scenes, with Turpin, Baudouin (Balduinus), and Ganelon. There are also statues, perhaps of Roland and Oliver, on the 12th-century porch of Verona cathedral, and until its destruction (between 1215 and 1220) there existed at Brindisi a mosaic (1178), in the pavement of the cathedral nave, depicting a battle scene in which were identified Roland, Oliver, and Turpin.

Historical Basis.—As recounted by contemporary chroniclers, the historical facts are somewhat different from the account given in the *Roland.* In the early summer of 778, Charlemagne, after receiving overtures from dissident Moorish leaders, led two vast armies, which converged on Saragossa with a view to occupying the town. The plot, however, miscarried, and on Aug. 15 he recrossed the Pyrenees into France, by a route not clearly defined. There (Arabic sources tend to suggest, in addition, a military reverse closer to Saragossa) his army was ambushed by Wascones (more probably Gascons than Basques), who, after inflicting heavy casualties and pillaging the baggage train, made off before any action against them could be organized.

To attempt to identify other early references to the *Roland* of Turold is to reopen the extremely complex problem of the origins of the poem and of the genre (*see* CHANSONS DE GESTE). The traditionalist interpretation of the evidence postulates the existence of an unbroken tradition of poems, very different from Turold's if only in that they excluded Oliver, reaching back to those composed under the immediate impact of Roncevaux. Joseph Bédier's individualist theory denies this continuity: ". . . if the legend of Roland may from an early date have vegetated obscurely in the churches of Roncevaux, it took shape in poetic form only in the 11th century." A. Pauphilet carried this argument further, answering Bédier's *"Au commencement était la route"* ("In the beginning was the pilgrim road") with *"Au commencement était le poète"* ("In the beginning was the poet"). It is generally agreed that there must have existed a *Chanson de Roland,* probably not fundamentally different in essentials from the recension contained in the conserved versions, about the middle of the 11th century, and that this bears the imprint of poetic creation in such essential aspects as the figure of Oliver and the presence of Turpin and Ganelon.

Although there is unequivocal proof, numismatic and diplomatic, of a Rodlandus or Rotholandus in the entourage of Charlemagne, the only historical evidence of a Roland among the fallen at Roncevaux is contained in the *Vita Caroli Magni* by Eginhard (Einhard, *q.v.*), which, briefly commenting on the defeat, lists among the dead Eggihardus, the royal seneschal; Anshelmus, count palatine; and *Hruodlandus Britannici limitis praefectus* ("Roland, prefect of the march of Brittany"). But the manuscript tradition of Eginhard is such that the authenticity of the four essential words is uncertain. The evidence of the intervening centuries is assembled and discussed in great detail by R. Menéndez Pidal in his important, but debatable, restatement of the traditionalist theory (see *Bibliography* below).

ROLAND HOLST-VAN DER SCHALK, HENRIETTE GOVERDINE ANNA (1869–1952), Dutch poet who also played an active part in political life, as a socialist. A lawyer's daughter, she was born at Noordwijk on Dec. 24, 1869. In 1896 she married the painter (later professor) Richard Nicolas Roland Holst (1868–1938), himself a talented prose writer. Her early poetry expresses the desire to understand life rather than a desire for beauty. Gradually influenced by William Morris' writings, she became a socialist. Her volumes of poetry *De nieuwe geboort* ("The New Birth," 1902) and *Opwaartsche wegen* ("Upward Ways," 1907) reflect her political ideals, but contain no proletarian poetry. In her drama *Thomas More* (1912), dedicated to the German socialist leader Karl Kautsky, she depicted the last days of the great humanist, whom she regarded as having anticipated her own ideals for mankind. She soon became internationally famous in left-wing circles. She took part in the Zimmerwald Conference (1915), and at first eulogized the Russian Revolution, but, after visiting Russia in 1925, she expressed her disappointment in Soviet Communism in her poems in *Heldensage* ("Heroic Saga," 1927). Her later work is religious and socialist in character. She withdrew from practical politics but remained loyal to her ideals, and her pacifist and anticolonial ideas attracted much attention. Apart from poetry and drama she wrote essays on art and politics, as well as biographies of such figures as Jean Jacques Rousseau (1912), Tolstoi (1930), Herman Gorter (1933), Romain Rolland (1946), and Gandhi (1947). She died in Amsterdam on Nov. 22, 1952.

ROLFE, FREDERICK WILLIAM (1860–1913), English author and eccentric, generally known by his pseudonym BARON CORVO, provides the curious example of an artist rescued from obscurity by his biographer. Twenty-one years after Rolfe's death A. J. A. Symons (1900–41), intrigued by the eccentricity, misery, and scandal of his private life, built up on these foundations his colourful biographical fantasy *The Quest for Corvo* (1934), the publication of which marked the beginning of Rolfe's fame. Neglected by his own and the succeeding generation, the intrinsic merit of Rolfe's writing was nonetheless always recognized by discerning critics and for incisiveness of expression he has few rivals in English prose. And in spite of failing to interest the common reader he had an important influence on contemporary writers, notably Henry Harland, R. H. Benson, Shane Leslie, and perhaps Ronald Firbank.

Born in London on July 22, 1860, Rolfe was the oldest of six children of a piano manufacturer. He left school at 14 and became successively a pupil teacher, an unattached student at Oxford, and a schoolmaster. Reared as a Protestant, Rolfe had from boyhood been drawn to religion, and his plans for a career in the church were laid in adolescence. In 1886 he became a Roman Catholic. There followed two unsuccessful attempts to become a priest, but the independence and perversity which were to mark and embitter his life finally led to his dismissal from the Scots College in Rome. This painful episode was to cause him lifelong frustration and to deepen the shadow of loneliness and persecution.

He now began a life unusual in its richness of incident and variety of adventure. For eight years he wandered about, turning his hand to painting, photography, tutoring, inventing, and journalism. In 1898, disclaiming all literary ambition—his faith unshaken in his vocation to the priesthood—Rolfe became a professional writer. During the next decade he published a collection

of short stories based on Italian folk tales entitled *In His Own Image* (1901; the first six of which had appeared in the *Yellow Book* under the title *Stories Toto Told Me*), a historical work, *Chronicles of the House of Borgia* (1901), a translation of the *Rubáiyát* of Omar Khayyam (1903), and two novels, *Hadrian the Seventh* (1904), an autobiographical fantasy, with which his name is chiefly identified, and *Don Tarquinio* (1905). Some of his works appeared after his death, notably *The Desire and Pursuit of the Whole* (1934), *Hubert's Arthur* (1935), *Nicholas Crabbe* (1958), and *Don Renato* (1963). Rolfe was a prolific letter writer and he engaged in long and violent correspondence with his enemies. An edition of his collected letters in ten volumes began publication in 1959.

Going to Venice for a short holiday in 1908 Rolfe stayed for the rest of his life. He found there, sailing his boat for days and nights on the lagoon, his happiest moments, and also suffered appalling privations. Short periods of extravagant living at the expense of friends and well-wishers and, more rarely, on money from his writings, alternated with periods of near-starvation. As in England, he was involved in many quarrels. For months he was homeless, sometimes living in an open boat. Yet he contrived to write his masterpiece *The Desire and Pursuit of the Whole*. All that is best and worst in Rolfe can be learned from this account of his years in Venice. Gifted at many points—Rolfe excelled as a swimmer, sculler, musician, photographer, painter, and scribe—in his books and letters he came near to self-expression, albeit neither to success nor satisfaction. For Rolfe was a man obsessed and his works bear the impression of the energy with which he carefully sought but never found the way out of his self-imposed martyrdom. Worn out, he died in Venice on Oct. 25, 1913.

ROLLAND, ROMAIN (1866–1944), French novelist, dramatist, essayist, and Nobel prizewinner (1915), was born at Clamecy (Nièvre) on Jan. 29, 1866. In 1892 he married Clotilde Bréal, whom he divorced in 1901. In 1895 he received a doctorate and became lecturer in history of art, first at the École Normale Supérieure, then, in 1904, at the Sorbonne, where he introduced the study of the history of music. He resigned in 1912 to devote his time to writing.

At the outbreak of World War I he was in Switzerland, and remained there, helping the Red Cross and publishing a famous series of articles, collected in *Au-dessus de la mêlée* (1915), urging France and Germany to respect truth and humanity throughout their fight. These aroused a storm of protest in both countries; the posthumous publication of his *Journal des années de guerre*, 1914–1919 (1952) has made possible a more dispassionate assessment of his attitude toward war. In 1922 he settled with his father and sister at Villeneuve (Vaud), where he remained until 1938, and where he was visited by friends from all over the world. In 1934 he married a young Russian widow and in 1937 he bought a house at Vézelay, in his native countryside, where he settled at the outbreak of World War II. He died there on Dec. 30, 1944.

At first Rolland wrote plays inspired by historical events: *Les Tragédies de la foi* (1913) contains *Saint-Louis* (1897), *Aërt* (1898), and *Le Triomphe de la raison* (1899), while *Le Théâtre de la Révolution* (1909) brings together *Les Loups* (1898; English translation *The Wolves*, 1937), *Danton* (1900; English translation 1918), and *Le Quatorze juillet* (1902; English translation 1928). His ideas on drama were expressed in articles collected in *Le Théâtre du peuple* (1903; English translation, *The People's Theatre*, 1918). In these plays, he aims at illustrating *"la vérité morale"* (*i.e.*, some general moral truth) rather than at exact historical accuracy. The heroes of his *Tragédies de la foi* are meant to embody a religious, national, or rationalist ideal. In his plays on the Revolution, he treats the problems of all periods disturbed by civil strife: the ends and means of political action, and the need to combine justice to the individual with the preservation of public order. *Les Loups* is an outstanding dramatic presentation of the Dreyfus affair (*see* DREYFUS, ALFRED). There followed *Le Temps viendra* (1903), inspired by the South African War; *Le Jeu de l'amour et de la mort* (1925), his most successful play; *Pâques-Fleuries* (1926), the prologue to his *Théâtre de la Révolution*; and *Les Léonides* (1928), its epilogue. To it he added *Robespierre* (1939).

His passion for the heroic also found expression in a series of *Vies des hommes illustres: François Millet*, published in English (1902); the brilliant *Vie de Beethoven* (1903; English translation 1907), first published in the *Cahiers de la Quinzaine*, edited by Charles Péguy, to whom he devoted his last work, *Péguy* (1944); *Vie de Michel-Ange* (1905; English translation 1912); and the *Vie de Tolstoi* (1911; English translation). Meanwhile, his studies in musicology were continued by his *Haendel* (1910) and by his great study of *Beethoven, les grandes époques créatrices*, seven volumes (1928–49).

These trends, added to his earlier project of writing a *Bildungsroman* (*i.e.*, a psychological novel), led him to create a hero of musical genius and German birth, "Jean-Christophe Krafft," whose life story he recounted in 17 numbers of the *Cahiers de la Quinzaine* (1904–12, definitive edition, five volumes 1931–34; one volume 1948). This outstanding novel-cycle introduced to France the *roman-fleuve* (or novel-sequence). In his preface Rolland explains that *Jean-Christophe* resembles a flowing river, developing and changing even when it seems most passive. The fame of this work throughout Europe, and the publication of *Au-dessus de la mêlée*, won him the Nobel Prize for Literature for 1915.

Jean-Christophe, an epic in conception and style, rich in poetic feeling, presents the successive crises confronting a creative artist who, even at moments of deep depression, is inspired by love of life. Translated into about 30 languages (English translation 1910–13; 1961–), it has induced young people everywhere to think about life and its problems, and has given them, through the very failure of its heroes, courage to live nobly. To Rolland, the development in it of the friendship between a young German and a young Frenchman symbolized that "harmony of opposites" which man should strive to establish first within himself, then between individuals and, finally, between nations.

After this major work, Rolland relaxed in writing a burlesque fantasy, *Colas Breugnon*, also glorifying life, but in the manner of Rabelais or of Voltaire's *Candide*. It was not published until 1919, in the same year as his allegorical play *Liluli*, a satire against war. *Pierre et Luce* and *Clérambault*, two novels published in 1920, continued to expound his views on war and national egoism. These views gained him sympathy among pacifists, although he must not be regarded as being one himself. Nor was he a Communist, although he followed the progress of Russia after 1917 sympathetically. Rolland entered with unusual understanding into the views of others, but regarded the claims of truth as paramount. His residence in neutral Switzerland and his writings gave him a unique position as a leading spirit of the "left," through his correspondence with Albert Schweitzer, Einstein, Gorki, George Bernard Shaw, Bertrand Russell, Rabindranath Tagore, and others—published in the *Cahiers Romain Rolland* (1948–).

At the end of World War I, he turned to Asia, especially to India, seeking to interpret its mystical philosophy to the West, and following sympathetically its struggle toward emancipation, in *Mahatma Gandhi* (1924), *Vie de Ramakrishna* (1929), and *Vie de Vivekananda et l'Évangile universel*, two volumes (1930; *see* also *Inde, Journal* for 1915–43; 1951). His part in founding the international review, *Europe* (1923), his participation in left-wing congresses and manifestos, his visit in 1935 to the U.S.S.R., have led to his, again wrongly, being identified with the Communist party. He remained, however, "one against all." But he was the declared enemy of the Fascist regimes of Mussolini and Hitler, in 1933 refusing the Goethe Medal and in 1939 accepting the war as inevitable. These feelings inspired the companion-piece to *Jean-Christophe*, *L'Âme enchantée* (seven volumes, 1922–33; one volume, 1951), which tells the life-story of a young, independent Frenchwoman, Annette Rivière, during and after World War I. Although less well known than *Jean-Christophe*, this novel-cycle has great spiritual strength, and concludes by exposing the cruel effects of political sectarianism. Its author was not only a coura-

geous and clear-sighted thinker, he was also a poet of sensuous imagery. Admirers of Paul Valéry and André Gide criticized his fluid, unaffected type of prose, capable of reaching a wide range of readers. His work was appreciated by Alain, however, and Gide, who was unsympathetic to *Jean-Christophe*, nevertheless recognized, in his *Journal* for 1917, that this *"livre barbare,"* as he called it, was one of the most topical works written in France in his generation.

Le Voyage intérieur (written 1926; publ. 1942) is a revealing and poetic self-portrait. The posthumous publication of Rolland's *Mémoires* (1956), and of part of his private journals, have made it possible to understand and to value more correctly the nature of his work and of his personality, and to recognize in him a man and a writer of exceptional integrity, with high critical and moral standards.

ROLLE, RICHARD, OF HAMPOLE (*c.* 1300–1349), early English mystic and author of mystical and ascetic tracts. The *Officium et Miracula,* prepared after his death by Cistercians of Yorkshire in anticipation of his canonization (which was never effected), provides the most certain information about his life: many apparently autobiographical passages in his own writings are cloudily expressed. Rolle was born *c.* 1300 at Thornton, Yorkshire, and was sent to the University of Oxford by Thomas Neville, archdeacon of Durham, but, dissatisfied with the subjects of study and the disputatiousness, left without a degree. There is no evidence that he ever went to the Sorbonne, or took priest's orders. Against the wishes of his family, Rolle established himself as a hermit on the estate of John Dalton of Pickering, but later moved to other hermitages, and probably always led a wandering life, rousing some opposition but winning much admiration. He kept in touch with a number of religious communities in the north and seems to have become spiritual adviser to the nuns at Hampole, in south Yorkshire, before his death there on Sept. 29, 1349. His influence and reputation lived to the Reformation.

It is often difficult to distinguish his writings from those of his many followers. *The Pricke of Conscience,* formerly ascribed to him, has been denied him by 20th-century scholars. Among the genuine works is a number of scriptural commentaries of which that on the Psalms is the most important. Two distinct versions exist: one in Latin, the other written in English at the request of Margaret Kirkby, a recluse at Anderby, Yorkshire. His range of reading is wide: he draws on Gregory, Anselm, Bernard, Peter Lombard, the Victorines, Bonaventura; his knowledge of the Bible is profound. Among his Latin treatises, *Melos Amoris* is something of an *apologia* offered to his detractors. *Incendium Amoris* most comprehensively presents his doctrine which, though in the main conforming with the usual mystical theology of the late middle ages, has some emphases and terms of its own. Throughout his diffuse and repetitious writings the life of contemplation and solitude is exalted. Strict physical self-control is urged, but spiritual progress consists in the development of love of God. This life of love is consummated in mystical union, which is considered to be self-authenticating. Rolle's method is essentially a concentration and directing of the affections toward the person of Christ, with a resulting experience of intense joy. In *Melos,* ch. ix, and *Incendium,* ch. xv, he provides notable accounts of rapture, which he invariably refers to in terms of *calor, dulcor, canor* ("fire, sweetness and song"). The terms suggest the quasi-physical accompaniment of his own mystical experiences.

His English writings on similar themes, handled more simply, include *Ego dormio* for a nun at Yedingham, Yorkshire, the *Commandment of Love to God* for a Hampole nun and the *Form of Perfect Living,* for Margaret Kirkby again. Rolle's literary importance lies in these contributions to the vernacular stream of devotional prose for women readers. His English prose style is much commended: it is lively, persuasive, highly figured. The verse ascribed to him has more fervour than grace. Although he had mastered scholastic style, his Latin prose is usually fantastically rhetorical, exhibiting a curious syntax, a rich, obscure vocabulary and heavy alliteration and assonance.

BIBLIOGRAPHY.—C. Horstmann's edition of his works, in *Yorkshire Writers,* 2 vol. (1895–96), provided the basis of later study. H. E. Allen, "Writings Ascribed to Richard Rolle, Hermit of Hampole, and Materials for his Biography," *Publications of the Modern Language Association of America* (1927), established the canon. Editions are: *English Writings of Richard Rolle, Hermit of Hampole,* ed. by H. E. Allen (1931); *Incendium Amoris,* ed. by M. Deanesly (1915); *Melos Amoris,* ed. by E. J. F. Arnould (1957); *Officium de Sancto Ricardo de Hampole,* ed. by G. G. Perry, Early English Text society, rev. ed. (1921). *See* also F. M. Comper, *The Life of Richard Rolle* (1928); for Rolle's literary position, R. W. Chambers, *On the Continuity of English Prose* (1932). There is a full bibliography in J. E. Wells, *A Manual of the Writings in Middle English, 1050–1400* (1916) and *Supplements* (1919–35). (G. SD.)

ROLLER, one of several old world birds, especially the common roller (*Coracias garrulus*), so called from its way of occasionally rolling in its flight, after the fashion of a tumbler pigeon. It is widely though not numerously spread over Europe and western Asia in summer, breeding as far north as the middle of Sweden, but retiring to winter in Africa. It is seen almost every year as a straggler in the British Isles. Except the back, scapulars and tertials, which are bright reddish-brown, the plumage of both sexes is blue (of various shades, from pale turquoise to dark ultramarine) tinted in parts with green. The bird is purely insectivorous.

Coracias forms the type of the family Coraciidae, allied to the bee eaters (Meropidae) and kingfishers (*q.v.*) (Alcedinidae), in the order Coraciiformes. There are 16 species, found throughout Europe, Asia and Africa. The oriental roller or dollarbird (*Eurystomus orientalis*) ranges from southern Siberia to Australia.

ROLLER SKATING. Roller skates and the sport of roller skating have been traditionally accredited to an unknown Hollander who during the early 18th century created crude devices that could be strapped to his feet in the manner of early ice skates. The first record of roller-skate manufacture is by Joseph Merlin of Huy, Belg. A contemporary described "a pair of skaites" as being among Merlin's many inventions while he was living in London shortly after 1760. Other early roller skates include the French *patin-à-terre* and the German *Erdschlittschuh* (both terms meaning literally "ground skate"), each about 1790. Several attempts were made to improve upon the traditional four-wheeled roller skate by aligning the wheels after the fashion of the ice skate blade and in numerous other ways. None proved satisfactory, and further manufacture of the product adopted the earliest idea, still the design of roller-skate equipment.

During the 19th century considerable trial and error went into the search for an action device that would allow its user to perform upon curved strokes (again similar to the action of the "rocker style" ice skate) and thus take better advantage of the force of gravity in keeping a firm and upright balance. Until the invention of the now common cushioned truck for roller skates by James L. Plimpton of Medfield, Mass., in 1863, roller skating was not widely popular; the sport was simply too difficult to master. Plimpton patented his rocking skate that year, and the first great roller-skating craze swept the United States and western Europe. The first of the large roller-skating rinks was opened in New York that year, and the first organized roller skating was developed.

Shortly before Plimpton's rocking skates appeared, the composer Giacomo Meyerbeer had written into his opera *Le Prophète* an ice-skating scene, which was performed on the stage on roller skates. The opera was a great success and the skating scene became famous. In 1849 the choreographer and composer Paul Taglioni wrote a ballet, "The Skaters," again depicting an ice-skating scene, again performed on roller skates. In spite of the difficulties in performing upon the earlier roller skates, a U.S. ballet master, Jackson Haines, who had mastered ice-skating techniques with the application of ballet technique, turned his attention to roller skating; beginning in 1864 he captivated all who saw him perform. His interpretations became the foundation for what is known as the "international style" of skating on both ice and rollers, and his influence is still felt. One of the unusual posi-

tions in spinning is officially named after Haines.

Roller-skate wheels (or rollers) became the next subject of research. In the early skates Turkish boxwood had been widely used. The ball-bearing wheel, patented by Levant M. Richardson in 1884, required a better substance, and during succeeding years maple and then a fibre were introduced.

Throughout the years a variety of surfaces have been used for roller-skating rinks. However, nothing has provided a better floor than the fine, close-grained wood of the American sugar maple, preferably from trees grown in the northlands of Maine, Michigan, Wisconsin, and Minnesota.

Roller skating has been a widely popular children's sport for many years, practised outdoors on streets and sidewalks with steel-wheeled clamp-on skates. Roller speed skating became a highly skilled and well-attended event during the first quarter of the 20th century. Gradual growth of roller skating as a participant sport during the early 1930s brought about in the U.S. the organization of a large and permanent association, the United States Federation of Amateur Roller Skaters. This was one of the first to be completely separated from the control of and linkage with the ice-skating sport. In England the two sports have been tied together for nearly 100 years. There has been gradual organization throughout the world, but however extensive the organizing efforts, only a very small fraction of all roller skaters belong to the associations.

ROLLI, PAOLO ANTONIO (1687–1765), Italian poet and librettist who played a leading part in the italianization of taste in 18th-century London, was born in Rome on June 13, 1687, the son of an architect. As a young man he studied with Gian Vincenzo Gravina; and in 1715 he went to England as the protégé of Lord Thomas Pembroke. Soon after his arrival Rolli was appointed Italian master to the royal household; and during a sojourn lasting for some 30 years (1715–44) he wrote many cantatas and operatic libretti which were set to music by Bononcini (*Astarto*), Handel (*Il Floridante*), and Porpora (*Arianna in Nasso*). Rolli is best remembered however as the author of innumerable *endecasillabi*, odes, and *canzonette* in which he aspired to recapture the rhythms of Catullus and the lighthearted charm of Anacreon. His other works include a translation of *Paradise Lost* (1735), *Marziale in Albion* (published posthumously 1776), and editions of the Italian classics. Rolli died at Todi on March 20, 1765.

ROLLS, CHARLES STEWART (1877–1910), English pioneer motorist, aviator, and automobile manufacturer, technical managing director of Rolls-Royce Ltd., was born in London on Aug. 27, 1877, the third son of Lord Llangattock. He was educated at Eton and at Trinity College, Cambridge, graduating in mechanical and applied sciences. Rolls owned and drove a car prior to the Locomotives on Highways Act of 1896, commonly called the "Emancipation" act, and in the early days he drove George V and Queen Mary when they were prince and princess of Wales. He drove his own 12 hp. Panhard car in the Thousand Miles Trial of 1900 and took part in many of the early long-distance European classic races. In 1902 he started in business as a motor dealer, and in 1906 his firm merged with the company of Sir Frederick Henry Royce to form Rolls-Royce Ltd. Rolls was the first man to fly across the English Channel and back nonstop, in 1910, but on July 12 of that year he was killed in a flying accident at Bournemouth, Hampshire.

RÖLVAAG, OLE EDVART (1876–1931), Norwegian-American novelist and educator, noted for his realistic portrayals of Norwegian settlers on the Dakota prairies and the clash of transplanted with native cultures in the U.S. He was born April 22, 1876, on the island of Dönna, Norway, emigrated to the U.S. in 1896, and was naturalized in 1908. Educated at St. Olaf College, Northfield, Minn., and the University of Oslo, Norway, he spent most of his life at St. Olaf as a teacher of Norwegian language and literature and the history of Norwegian immigration. He wrote in Norwegian, the language in which his works were originally published, and worked closely with the translators on the English versions. He died in Northfield on Nov. 5, 1931.

With literary antecedents reaching back to the Norse sagas and nearer influence from Henrik Ibsen, Jonas Lie, and Knut Hamsun, Rölvaag gave epic sweep to his picture of pioneering, but also deplored its cost in human values. A founder of the Norwegian-American Historical Association, he tirelessly urged immigrants to retain their customs, their speech, and their church, believing that American society would be the richer. *Giants in the Earth* (1927), his masterpiece, represented the positive joys of pioneering in the character Per Hansa, the negative griefs in his wife Beret. *Peder Victorious* (1929) and *Their Fathers' God* (1931) continued the story to the second generation in Per Hansa's son. *The Boat of Longing* (1933), which dealt with the newcomer in the city, and *Pure Gold* (1930), with immigrants whose search for money brought spiritual bankruptcy, were Rölvaag's only other novels translated into English.

See Theodore Jorgenson and Nora O. Solum, *Ole Edvart Rölvaag: a Biography* (1939). (C. E. BO.)

ROMA, in ancient Roman religion, the city of Rome personified and later worshiped as Dea Roma. She was first revered simply as the genius or guiding spirit of the city and from this came to be worshiped as a goddess. Like emperor worship, the worship of Roma flowered first in the provinces. She had temples in Asia Minor as early as the 2nd century B.C. (Tacitus, Annals, iv, 56), often in association with other deities (*e.g.*, Tyche, Greek goddess of fortune; *cf.* Fortuna). From the time of Augustus the worship of Roma and the emperor in association became widespread outside Rome, but it was not until the time of Hadrian that Roma was recognized officially with the construction of a temple of Venus and Roma on the Velia. Her representations are numerous. Her head, symbolic of the Roman state, appears continuously on republican coins. In the empire she is a goddess with the symbols of war, victory, and plenty.

ROMAINS, JULES (originally LOUIS HENRI JEAN FARIGOULE) (1885–), French poet, dramatist, and novelist, a founder of the literary movement known as *Unanimisme* and author of two works that have achieved international fame, the satire *Knock* and the novel-cycle *Les Hommes de bonne volonté* (*Men of Good Will*). He was born at La Chapuze, Saint-Julien-Chapteuil, in the Cévennes, on Aug. 26, 1885. The son of a schoolmaster in Paris, in 1906 he entered the École Normale Supérieure, where he took degrees in both science and philosophy. After teaching philosophy, in 1919 he decided to devote his time to writing and to travel, both privately and as a delegate to international congresses of writers. He became president of the International Federation of P.E.N. Clubs in 1936. In 1940, when the German Army occupied France, he took refuge in the United States, and lived there and in Mexico until the end of the war. Soon after his return to France in 1946, he was elected to the Académie Française. In 1953 he legally adopted the name Jules Romains, which he had used as a pseudonym except for a scientific work, *La Vision extra-rétinienne et le sens paroptique* (1920).

Before World War I, Romains was known mainly as a poet and as founder, with Georges Chennevière, of *Unanimisme*, a movement which combined belief in universal brotherhood with the psychological concept of group consciousness, and emphasized the transcendent power of collective emotion and the life of the human group as a whole. His first important book of poems, *La Vie unanime* (1908), was published by the Abbaye, a community of writers and artists led by Georges Duhamel (*q.v.*), Charles Vildrac, Henri Martin-Barzun, and others, at Créteil, near Paris, with which Romains was closely connected. Later volumes of verse include *Odes et prières* (1913), *Chants des dix années 1914–1924* (1928; including *Europe*, written during World War I, which expressed both his despair at the defeat of internationalism and his faith in its reemergence), and *L'Homme blanc* (1937). The *unanimiste* theories of prosody are discussed in *Petit Traité de*

versification (1923), written with Chennevière.

Romains' first plays, *L'Armée dans la ville* (1911) and *Cromedeyre-le-Vieil* (1920), produced by Jacques Copeau (*q.v.*) at the Théâtre du Vieux-Colombier, were *unanimiste* verse-dramas as also were the tragedies *Le Dictateur* (1926; performed 1928) and *Jean de Maufranc* (1926; published 1927). Entirely different in conception and style were such farcical comedies as *Donogoo-Tonka* (1920), *Monsieur le Trouhadec saisi par la débauche* (1923), and, above all, *Knock, ou le Triomphe de la médecine* (1924; English translation, *Dr. Knock*, by H. Granville-Barker, 1925), in which Romains gave free rein to his gift for satire. *Knock*, a satire on the power of medicine to impose on human credulity, is a masterpiece of irony, wit, and comic invention. Acted and produced by Louis Jouvet (*q.v.*), it established Romains as a comic dramatist and gained a lasting place in the international repertory.

As a novelist Romains showed both the preoccupations that inspired his poetry and the qualities of invention that distinguished his plays. *Le Bourg régénéré, "conte de la vie unanime"* (1906), his first published prose work, describes how a village gains a sense of community. *Mort de quelqu'un* (1910) describes the reactions of a group of people to the death of an insignificant member of society, and traces his brief influence on their collective consciousness. *Les Copains* (1913) evokes both the bond which unites seven friends in their determination to shock society, and that which holds together the communities victimized by their practical jokes. A farcical tale, told with Rabelaisian gusto and truculence, it is one of Romains' most successful works. In the trilogy *Psyché* (1922–29), a study of erotic love, *unanimiste* theory is carried, not entirely successfully, to mystical heights: Romains is himself too much of a rationalist to enter fully into mystical experience.

His masterpiece, however, is the vast cyclic epic *Les Hommes de bonne volonté* (27 volumes, 1932–46; English translation, 14 volumes, 1933–46). This attempt to re-create the spirit of a whole era of French society—Oct. 6, 1908, to Oct. 7, 1933—resembles Balzac's *La Comédie humaine* in its ambition and scope. There is no central figure or family to provide a focus for the narrative as in the epic-cycles of Émile Zola and Roger Martin du Gard (*qq.v.*), and the stage is crowded with a huge cast of characters, some drawn from life, but most of them imaginary, and all typical of their period. The action presents successively great historical events (as in *Verdun*), intimate domestic scenes (as in *Éros de Paris*, 1932), and crimes or mysteries treated in the manner of a detective story (as in *Crime de Quinette*, 1932). Romains in turn probes into the souls of his characters, or presents an objective record of their everyday life. The best sections, magnificent portrayals of collective life and emotion—the frescoes of Paris on an autumn day (Oct. 6) in 1908 with which the series opens; during the victory parade after World War I; and on Oct. 7, 1933, in the last volume—exemplify the *unanimiste* method at its best, and are both moving and artistically satisfying. The two volumes which stand at the centre of the whole work, *Prélude à Verdun* (1937) and *Verdun* (1938), are remarkable pictures of the soul of a world at war.

It may be asked, "Who are the men of good will?" Romains makes it clear that they are the good, decent, humane people, men and women with a sense of humour and a respect for other people's ideas, who, though often unheeded, often themselves groping in the dark, yet strive for freedom, rejecting "foolishness, violence, collective crimes from which proceed all the ills of the world."

Volumes 19 to 24 of *Les Hommes de bonne volonté* were published in the United States and Mexico; the last three volumes appeared after Romains' return to France. He continued to write poems, short stories, novels, and essays, and in 1958 published the autobiographical *Souvenirs et confidences d'un écrivain*, but it was generally considered that his outstanding contribution to literature had been made in *Knock* and in the central volumes especially of *Les Hommes de bonne volonté*.

ROMAN, a town in Moldavia, northeastern Rumania, is situated at the confluence of the Moldova and Siret rivers, in the *regiune* (administrative and economic region) of Bacău. Pop. (1963 est.) 34,731. Founded by the ruling prince of Moldavia, Roman is first mentioned in documents dated 1392. The voivode Alexander the Good made it a bishopric, the seat of which was in 1467 burned down by Matthias Hunyadi, who himself was later defeated in the vicinity by Alexander's grandson Stephen the Great. Under the Communist regime, Roman became an important industrial centre, with a tube-rolling mill and food-processing and chemical factories.

ROMAN ARCHITECTURE refers to the architecture of the community of ancient Rome on the Tiber, as well as to that of the empire that spread from Britain to Mesopotamia, from the 5th century before Christ to the 4th century after Christ. Roman architecture was almost as complex as the Roman empire itself; it was influenced by a multitude of geographic, climatic, political, economic, social and cultural factors. The cohesive factor through all the differences was the Roman character, which possessed the talent and felt the necessity to organize in large and complex terms, politically or architecturally or otherwise.

(For a discussion of the architecture of classical Greece, from which many of the elements of Roman architecture were derived, *see* GREEK ARCHITECTURE. The impact of Roman architecture on succeeding cultures is discussed in BYZANTINE ARCHITECTURE and ROMANESQUE ARCHITECTURE. *See* also ARCHITECTURE and ROME: *The Ancient City.*)

Our knowledge of Roman architecture derives primarily from extant remains scattered throughout the area of the empire. Some are well preserved, others are known only in fragments and by theoretical restoration. Another source of information is the vast store of records, including dedicatory and other inscriptions on public works. Especially important is the book on architecture by Vitruvius (*q.v.*), who lived about the time of Christ. His book *De Architectura* is a handbook for Roman architects and covers almost every aspect of architecture, but it is limited, since it was based on Greek models and was written at the beginning of the more creative phase of Roman architecture, in the period of the empire.

HISTORY

Roman monumental architecture emerged around the 6th century B.C. as an Italic style, closely related to that of the Etruscans (*q.v.*). The Capitoline temple in Rome, built about this time, resembled Etruscan buildings at Signia, Orvieto, Veii and elsewhere, in resting on a podium with a triple cella, the broad low Etruscan porch and characteristic terra-cotta adornment. The Capitolium at the Roman foundation of Cosa, in the 3rd century, was similarly conceived. The forms, plastic and spatial, had evolved locally in a tradition of wood and terra cotta, though even at this time there was a slight Greek influence.

From about 200 B.C. to about A.D. 50, the rise of republican Rome and the increasing contacts with Greece resulted in a Greek influence strong enough to control the plastic forms and even to modify the spatial effects. A temple at Gabii, perhaps of the 3rd century, and the temple of Apollo at Pompeii of around 120 B.C., had approximately the Greek single-cella peripteral plan; the latter retained the Italic podium and open porch, and had pronounced modifications of the Greek Ionic order. Buildings like the temple under S. Nicola in Carcere (*c.* 31 B.C.), the round building by the Tiber (*c.* 31 B.C.), the Temple of Fortuna Virilis (*c.* 40 B.C.), all in Rome, show the height of the hellenizing movement. But the slightly later Augustan temples of Concord, Castor and Pollux in the Roman forum, and Mars Ultor in the Forum of Augustus had a native freedom of arrangement of the limited spaces, and highly elaborated moldings, particularly in the entablature, where new forms, mostly floral, were lavishly displayed in finely worked, full masses, and consoles became increasingly important.

During this period the more peculiarly Roman concepts developed chiefly in secular architecture. The Stabian baths at Pompeii, perhaps as early as 120 B.C., were already composed in vaulted spaces, though quite compactly and with little of the later freedom and spaciousness. In some buildings, like the Carcer and Tullianum of about 100 B.C. and the Tabularium, about 78 B.C., arches and concrete were basic, though hellenizing orders were used for ornament. The small theatre at Pompeii was built about 75 B.C. with the Roman interior forms already established but with no monumental exterior. The Theatre of Marcellus (*c.* 11–10 B.C.), however, had the high external façade with orders and arches blended, which became standard. The basilica, even of the 1st century, was experimental.

The beginning of Roman influence outside Italy is evidenced by theatres and amphitheatres at Arles and Nîmes, perhaps as early as 30 B.C.; by the Maison Carrée at Nîmes about 16 B.C.; and by small buildings in Greece and Syria, about the turn of the century.

Around the middle of the 1st century A.D. there was a surge of development of spatial composition. The orders and other ornament inherited from Greece were increasingly modified and elaborated in nonfunctional perspective effects, and other kinds of ornament and spatial configurations gained importance. Of course many buildings like the Colosseum (A.D. 75–82) preserved a more conservative character, but with the baths and palaces of Nero began the series of imperial compositions of grand, elaborate spaces. The movement came to a climax under Trajan and Hadrian (*c.* 98–138): in the Forum of Trajan and the great complex at Baalbek; the Pantheon; the villa of Hadrian at Tivoli, with its intricate composition of enclosed spaces and interrelated buildings and of interior and exterior vistas.

Through the 2nd and 3rd centuries countless buildings were erected in cities and towns all over the empire, in part under imperial patronage, in part by local enterprise. The provincial buildings had great individuality, but the more ambitious usually followed the influence of the capital. The forms evolved by about A.D. 140 were followed conventionally for the next 50 years—and longer—but from about A.D. 200 to the age of Constantine, there was a growing trend toward increased majesty and less emphasis on material substance. Even before the end of the 2nd century deep cutting with sharply contrasting light and shadow had begun to detract from the impression of the solid forms in carved ornament; in the arches of Septimius Severus (*c.* A.D. 200) light and shadow alone formed the design, not the masses of the forms of the motifs. Especially in Africa illogical composition of the elements of entablatures robbed them of structural significance. In the palace of Diocletian (*c.* A.D. 300) extensive use of arched colonnades, free and blind—even, as at the main gate, on consoles—emphasized the movement rather than the mass. The sheer faces of some wall surfaces, like those of the towers flanking the gates, became, with a minimum of structural articulation, austere geometric forms. Experimentation and elaboration in vaulting, as in the Temple of Minerva Medica (*c.* A.D. 260), was toward making the supports lighter structurally and aesthetically. Compared to the Baths of Caracalla (*c.* A.D. 215), the Basilica of Maxentius (*c.* A.D. 310–320) was more simple and concentrated, increasing its sense of elemental vastness and permanence, whereas in contrast to the Pantheon its shape and ornament is less tangible.

Finally, evolving into the early Christian art to come, the Constantinian mausoleum of Sta. Costanza, with its dome resting on a drum supported on arches on a circle of pairs of slender columns, and its ambulatory vaults smooth and sheathed with mosaic, already was striving to suggest the independence of roof and space from material support.

BUILDING TECHNIQUES

Building Materials.—The material employed around Rome in the earliest buildings was tuff, a volcanic rock of varying hardnesses, some soft enough to be worked with bronze tools. Later other harder volcanic stones were used such as peperino and the stone from the Alban hills. Under the later republic and the empire the most important stone for building was travertine, a limestone quarried mainly at Tibur (Tivoli). An example of the use of travertine is the exterior of the Colosseum.

The use made by the Romans of marble was mainly decorative. It was applied in slabs to brick and concrete walls, and set in cement. It was used for pavements either in slabs cut and arranged in patterns, or as mosaic. Under the empire a great demand arose for coloured marbles and such stones as porphyry, granite and alabaster, which were imported from various parts of the empire. The abundant use of these marbles is well illustrated by the remains of the Flavian palace on the Palatine and of Hadrian's villa at Tivoli.

Unburned bricks faced with stucco were used especially for private houses under the republic. Of these, naturally, very few remain. Under the empire kiln-baked bricks and tiles were the most common facing for concrete. They were never used to build a whole wall in the modern manner but merely as a protective skin. These bricks or tiles were almost always used in triangular shapes. Large tiles about two feet square called bipedales were employed as bonding courses. (*See* also BRICKWORK.)

The use of stucco over unbaked brick and over coarse stone was prevalent from the earliest times in Greece, Sicily and Italy. It served as a protection against the weather and also as a finish. Later it was used over brick and concrete. It was often made of lime, sand and fine marble dust and some would take a high polish or fine molding. Thus it became the usual ground for decoration especially in the interiors of houses. Examples of its use abound at Pompeii, and at Rome in the House of Livia, in Nero's Golden house and others. Another material the use of which was mainly decorative is bronze. Doors, grilles, panels of ceilings, etc., were made of it.

For their concrete the Romans used pozzolana, of which there are extensive beds at Pozzuoli, near Naples, and also around Rome. It is a fine chocolate-red volcanic earth, which when mixed with lime forms an excellent natural hydraulic cement that will set well even under water. With this cement was mixed an aggregate of broken tuff, travertine, brick or even marble, pumice stone being used in vaults after the 1st century A.D. to lighten the weight. It was used in all the great imperial buildings (*e.g.*, Pantheon, Baths of Caracalla and Basilica of Maxentius). The new forms of architecture that were developed by the use of this material spread all over the Roman empire, although in the provinces other, often weaker, kinds of concrete were used.

Construction.—Walls were built of ordinary masonry or of concrete (faced or unfaced). While there are several examples of early stone walling without courses (cyclopean and polygonal) especially in some towns (*e.g.*, Norba, Praeneste, near Rome), most of the stone walls existing were built of squared blocks laid in regular courses as headers and stretchers (*opus quadratum*). The blocks of stone in these walls are fairly large, 2 ft. by 4 ft. or more, and were often held together by iron cramps fixed in lead.

Concrete walls, except below ground, were always faced. They are divided into types according to the kind of facing used. (1) *Opus quadratum, i.e.*, ordinary stone walling, was used as a facing for concrete, especially for important public buildings under the earlier empire (*e.g.*, exterior of the Colosseum). (2) *Opus incertum* was the most common facing for ordinary concrete walls of the 2nd and 1st centuries B.C. The face of the concrete was studded with three-inch to four-inch irregularly shaped pieces of stone, usually tuff. (3) *Opus reticulatum* came into vogue in the 1st century B.C. and remained until the time of Hadrian. The construction was like that of *opus incertum* but the pieces of stone were pyramid shaped with square bases set diagonally and wedged into the concrete walls. (4) Brick- and tile-faced concrete (so called *opus testaceum*) was by far the most common material for walling under the empire. Triangular tiles were used with their points turned into the concrete and their long sides showing, thus giving the appearance of a wall built of thin bricks. Bonding courses of bipedales were employed at intervals of two or three feet. (5) Mixed brick and stone facing (called *opus mixtum*) was popular under the later empire and especially under Diocletian.

Other kinds of supports included columns and piers. Columns were usually of stone and often monolithic; occasionally small

columns were of brick covered with stucco. Piers, too, were often of stone, but those serving as primary support for large vaults were usually of concrete.

Columns and piers both bore horizontal architraves or, from the 2nd century B.C. (later for columns), arches. These occurred in gates, bridges and aqueducts as well as colonnades and doors and other openings. Not only round but segmental and flat arches were used freely. The discovery of concrete enormously facilitated the spread of arch construction. Concrete arches were faced with stone or tile voussoirs.

The vaults used by the Romans were simple geometrical forms: the barrel vault, the intersecting (groined) barrel vault and the segmental vault. By the 1st century B.C. extensive systems of barrel vaulting were employed (*e.g.*, in the substructions of the Tabularium in Rome, the Temple of Hercules at Tivoli and others). When set the concrete vault exerted no thrust. The surfaces of the vaults were tile faced or covered with stucco. A fine example of Roman vaulting is the Basilica of Maxentius. (*See* also ARCH AND VAULT.)

The construction of the dome (*q.v.*) naturally follows that of the vault. Here again the fact that the concrete dome was a dead weight without thrust simplified the problem. Tie ribs of brick were used and sometimes relieving arches, as in the case of the Pantheon where the facing bricks were laid horizontally. At the crown of the dome was a brick ring. Characteristic of imperial Roman design was the elaboration of complex forms of domes to fit multilobed ground plans.

Most monumental buildings were erected for public use and the income, if any, from rents or fees went to the public treasury. Many of these, however, were built by wealthy individuals and given to the community in a form of voluntary but well-recognized income tax. Construction was done by state agencies or private contractors, employing slave or free labour. Techniques and crafts were highly developed, though machines were simple and powered by men or animals.

Design.—The pervasive Roman predilection was for spatial composition, for organization of lines and surfaces and masses and volumes in space. In this the Romans differed from their predecessors in the ancient Mediterranean world, and however freely they used the elements of earlier styles, in Rome or in the provinces, they recast them according to their own taste.

Their most conspicuous inheritance was the order (*q.v.*). The columns and their associated motifs of superstructure were taken directly from Greek tradition, with little alteration of major form, although the Romans did use them with little attention to their internal logic. There were five orders of Roman architecture: Tuscan, Doric, Ionic, Corinthian and Composite. Tuscan and Composite were modifications of Doric and Corinthian respectively. In general the proportion of the Roman order was slenderer than that of the corresponding Greek order and there was a tendency toward greater elaboration. Columns were often unfluted, but the faces of the entablature, left plain in Greek work, were covered with decoration.

The Doric order almost invariably had a base molding that was probably taken from the Etruscan Doric or Tuscan column. Examples of Roman Doric are to be found in the Tabularium (78 B.C.) and in the lowest order of the Colosseum (A.D. 79) where it was used in conjunction with the arch. The Temple of Hercules at Cori (*c.* 80 B.C.) is one of the few known Roman Doric temples.

The Ionic order was used in some temples and public buildings and the number of isolated capitals found suggests that it had a certain vogue in private homes. Notable examples of this order are the Temple of Fortuna Virilis, the second orders of the Theatre of Marcellus and the Colosseum, Trajan's forum at Rome and various buildings at Pompeii.

The Corinthian order was by far the most popular with the Roman builder. It was popular for its richness and for the ease with which it could be used in any position resulting from the identity of the four faces of the capital. The columns removed (by Sulla) from the temple of Zeus Olympios at Athens were the model, but the whole order became progressively elaborated in detail and showed a tendency toward sharp contrasts of light and shadow. Examples of this order are seen at the temples of Mars Ultor and of Castor and Pollux (the latter is one of the most beautiful examples in Roman architecture) in Rome, the Temple of Vesta at Tivoli, Agrippa's portico to the Pantheon and the third order of the Colosseum.

The Composite capital is really a Corinthian capital with the tendril at the corner replaced by an Ionic volute. Examples of this capital are to be found on the triumphal arches of Titus and Septimius Severus and the Baths of Diocletian. (*See* also CAPITAL.)

Although these forms were taken bodily from Greek architecture their real use in Roman design was wholly different. In Roman work columns came to carry arches as well as architraves, permitting more varied linear patterns, wider intercolumniations and greater freedom in articulating spatial forms. Moreover, columns were used not only as primary supports but also as detached columns and pilasters, together with other projecting elements and recessed niches of all kinds, so as to modulate the sheer face of wall or pier into a composition of mass and volume in depth, supplementing the larger forms of the main volumes. Realistic or fanciful architectural compositions were even painted on some walls to give an illusion of the same effect. So, too, carved moldings, cornices, etc., were designed with deep interplay of mass and volume.

In terms of primary architectural forms, Roman design from its first emergence from the Italic and Etruscan traditions favoured temples with spacious porches, like the Temple of Apollo at Pompeii. The very elevation of the podium poses the temple in the surrounding volume, with external spatial relationships established by the special approach and enclosing colonnades. In imperial architecture the design of the temple precinct, forum, thermae, etc., was normally conceived as a complex of variously formed spaces related to variously formed masses; even landscaping was incorporated, as, conspicuously, at Tivoli and Praeneste. Interiors of smaller houses as well as of grand structures were designed in terms of vistas through variously shaped rooms of varying qualities of illumination. There was a powerful, even rigid final dominant of axial symmetry, but against this was exploited richly every kind of spatial form in some highly developed system of organization.

TYPES OF BUILDING

Temples.—The Roman temples differed in many important respects from those of the Greeks. For the comparatively low stylobate with its three steps all round, the Romans substituted a high platform or podium with a flight of steps on the entrance façade. Greek temples were isolated from other buildings and almost always faced east and west; those of the Romans were turned to all points of the compass, their orientation being governed by their relation to other buildings. This resulted in an increased emphasis on the entrance façade, with an increased depth to the portico. The cella was wider and the colonnade that surrounded the Greek temple was often reduced to a row of engaged columns or pilasters along the cella walls, except on the entrance front. In some cases the cella was vaulted in concrete and might have an apsidal end (*e.g.*, the so-called Baths of Diana at Nîmes and especially the double Temple of Venus in Rome). The best preserved example of a Roman temple now existing is that known as the Maison Carrée at Nîmes. Among the most important temples of which remains exist are those of Fortuna Virilis, Mars Ultor, Castor and Pollux, Concord and Antoninus and Faustina in Rome; in Italy, the Temple of Minerva at Assisi and the temples at Pompeii; and in Syria, the temples of Bacchus at Baalbek and of the Sun at Palmyra.

Among the most important circular temples are those of Vesta and Mater Matuta in Rome, Vesta at Tivoli, Rome and Augustus on the Acropolis at Athens, and Venus at Baalbek, which has detached Corinthian columns joined to the cella walls by a segmental architrave. The greatest circular temple and in many respects the most important Roman building is the Pantheon (*q.v.*). It consists of a rotunda about 142 ft. in diameter surrounded by concrete walls 20 ft. thick, in which are alternate circular and

rectangular niches. Light is admitted through a central opening about 28 ft. across, at the crown of the dome. In front is a portico which originally belonged to a temple built by Agrippa, re-erected when the rotunda was built under Hadrian, A.D. 120–124. The rotunda and the dome are among the finest examples of Roman concrete work. The construction is strengthened by immense relieving arches and piers of brick set above one another in the thickness of the walls. The interior was lined with precious marbles, the coffers of the dome were decorated with bronze rosettes and the dome itself was covered externally with bronze plates. (*See* also TEMPLE ARCHITECTURE.)

Tombs.—The large Roman tomb consisted of an earth mound or tumulus surrounded by a ring of masonry rising usually to a considerable height. Few of the type now exist, the most notable being the tomb of Cecilia Metella on the Via Appia and the mausoleum of Hadrian, now the castle of St. Angelo. The smaller tombs, in particular those of the columbarium (*q.v.*) type are usually underground, though there is sometimes an upper story (often in the shape of a small temple *in antis*) built of brick, from which steps lead down to the tomb proper. There is a line of such tombs just outside Rome along the Via Appia and also along the Via Latina and such a cemetery has been found under the church of St. Peter in Rome. Examples of Roman funeral monuments of various kinds exist along the Street of Tombs at Pompeii and in the provinces (*e.g.*, at Palmyra, Jerusalem and Petra).

Forums and Markets.—A principal focus of Roman life anywhere was the forum. This was a place or space in which important business might be conducted. In a small community most business would be conducted in a forum, though gradually special buildings were built on the periphery for particular activities, civic, commercial, religious. Characteristically such a forum was lined in part with small one-room shops built in long, low buildings, sometimes with colonnades.

A city might have more than one forum, for special reasons. Conspicuous examples are the imperial forums in Rome itself, of which the Forum of Trajan is the most developed example. It consisted of a colonnaded square with great hemicycles on the sides and the tremendous Ulpian basilica lying across one end; beyond the basilica was a library with the commemorative Column of Trajan in the central court, and beyond this a (slightly later) temple in another colonnaded square. (*See* also GOVERNMENTAL ARCHITECTURE.)

Architecturally and functionally distinct from the forum, though superficially similar, is the *macellum*. This was not a square, but a market building consisting of shops around a colonnaded court. Great warehouses, called *horrea*, were another kind of market building.

Basilicas.—The basilica (*q.v.*) was a large covered hall for the holding of courts of justice and for banking and other commercial transactions. On the forum at Rome are the Basilica Julia on the south side and the Basilica Aemilia on the north side, both of which had a central hall and side aisles. The Basilica Ulpia in Trajan's forum was similar in plan but had at either end semicircular halls which served as law courts. The fourth and greatest of the basilicas was that begun by Maxentius and finished by Constantine, *c.* A.D. 313. This huge building covered 7,000 sq.yd. and followed in construction and plan the great hall of the Roman baths. The vaults over the bays on the north side are still to be seen overhanging without support, a striking testimony to the marvelous cohesion and enduring strength of Roman concrete. The basilica at Pompeii is an example of the simpler type general in the provinces.

Baths.—By the end of the republic, baths (*balneae*) had become a recognized feature of Roman life. Under the empire their numbers increased until at the beginning of the 4th century A.D. they numbered 1,000 in Rome alone. They were of the type of the Turkish bath with rooms at different temperatures. Remains of these ordinary establishments are common throughout the empire. The Stabian baths at Pompeii are the best preserved.

The imperial thermae were more than baths. They were immense establishments of great magnificence with facilities for every gymnastic exercise, with halls to which resorted philosophers, poets and rhetoricians and those who wished to hear them. The earliest of these thermae were those built by Agrippa *c.* 21 B.C. Others were built by Nero, Titus, Trajan, Caracalla, Diocletian and Constantine. The best preserved are the Baths of Caracalla, which covered an area about 1,000 ft. square, and those of Diocletian with accommodation for 3,200 bathers. Parts of the latter are now occupied by the church of Sta. Maria degli Angeli and by the Museo delle Terme. The remains of these two great establishments are among the most impressive examples of Roman concrete construction. (*See* also BATH.)

Theatres, Amphitheatres, Circuses.—The Roman theatres differed in several respects from the Greek. The auditorium was not excavated and the walls surrounding stage and seating were continuous, the entrance to the orchestra being by vaulted passages. As the chorus played no part in the Roman theatre the orchestra or dancing space became part of the auditorium. The façade behind the stage was elaborately adorned with architectural fantasies.

The only theatre in Rome of which any remains exist is that of Marcellus built by Augustus (*c.* 11–10 B.C.) but there are numerous examples throughout the Roman empire especially in Asia Minor. The theatre at Orange, France, is the best preserved example. Others of importance are those at Taormina in Sicily; Pompeii and Ostia in Italy; at Termessus, Alinda, Aizani, Aspendus in Asia Minor; the Odeon of Herodes Atticus at Athens. The Odeon of Agrippa in Athens was a good example of a completely enclosed music hall.

The largest and most important amphitheatre (*q.v.*) of Rome was the Colosseum built by the emperors Vespasian, Titus and Domitian in A.D. 72–80 on the site of Nero's lake. It is a huge ellipse about 620 ft. by 513 ft. covering six acres and shows remarkable skill in planning. It had seating accommodation for about 45,000 spectators, and its 80 entrances were so arranged that the whole building could be cleared in an incredibly short time. The whole is built of concrete, the exterior being faced with travertine and the interior with precious marbles that have long since disappeared. Other important amphitheatres are those at Capua, Pompeii, Pozzuoli, Verona, in Italy; Pola, in Yugoslavia; and Arles and Nîmes, in France.

The circus (*q.v.*) was essentially a racecourse, lined, ideally, with tiers of seats along each side and curving around one end, with the opposite end squared off and provided with arrangements for chariots to enter and draw up for the start. Down the middle ran a barrier, on which judges and referees might perform their functions. Since it was the largest facility for watching some function the circus was used for other spectacles than racing, such as, traditionally, for the burning of the Christians by Nero.

Streets, Arches, Gateways.—Characteristic of Roman towns were colonnaded avenues for main lines of traffic; even secondary streets were sometimes lined with colonnades for protection from weather. Such avenues were sometimes adorned with ornamental arches. Often these served simply to dramatize or punctuate the implied movement of the avenue. A triumphal arch (*q.v.*) was sometimes erected to commemorate an important event or campaign, often isolated rather than spanning a roadway. The triumphal arches of Septimius Severus at Rome and of Trajan at Ancona are accessible only by flights of steps and the archways themselves are too narrow for ordinary use. The triumphal arch was usually decorated with columns and bas-reliefs of the chief events it commemorated and was frequently surmounted by a group of sculpture. The most important of these arches are the Arch of Titus (*c.* A.D. 81) commemorating the capture of Jerusalem, the arches of Septimius Severus and Constantine in Rome and Trajan's arches at Benevento and Ancona. There are several other triumphal arches in the provinces, notably those of Tiberius at Orange, of Augustus at Susa and Caracalla at Tebessa. Others exist at Reims, Pola, Timgad and Maktar.

The monumental city gate while sometimes serving a commemorative purpose differs from the arch in being part of the defenses of the city. Of these gates one of the most famous and best preserved is the Porta Nigra at Trier. (*See* also MONUMENTS AND MEMORIALS.)

Bridges and Aqueducts.—The bridges (*q.v.*) and aqueducts (*q.v.*) of the Romans rank among their greatest monuments. They knew the principle of siphon conduits, but the conduit elevated to grade on arches or even tiers of arches was often cheaper for them and always more spectacular. The most famous examples of Roman aqueducts are the Pont du Gard at Nîmes, the aqueducts at Tarragona and Segovia in Spain, and those which crossed the Campagna bringing water to Rome.

There are not many of the larger Roman bridges now remaining. The best preserved is that built by Augustus and Tiberius at Rimini. The finest is that across the Tagus at Alcantara in Spain.

Domestic Architecture.—Private houses, even palaces, were usually of the style that emphasized interior courts and gardens rather than external façade; this tradition was even maintained so far as possible in northern Europe and Britain, where elaborate arrangements for heating had to be added. In the native Mediterranean climate, however, construction tended to be light and open rather than compact and imposing.

Even the palaces of the Caesars in Rome consisted essentially of series of gardens and, considering their purpose, relatively unmonumental buildings, spread somewhat casually over the Palatine hill. Augustus himself bought and enlarged the house known as the House of Livia which still exists. Tiberius built a palace on the northwest side of the hill. Another palace was built on the southeast corner of the hill by Claudius or Nero. The central space was covered by the palace of the Flavians, Domitian with his architect Rabirius being responsible for a magnificent suite of state apartments and for the sunken garden called the *hippodromus*. Hadrian extended the palace toward the forum. Septimius Severus raised a huge structure overlooking the Circus Maximus, partly on top of Hadrian's work and partly on an artificial platform supported on arches, finishing it with his Septizonium. Of the famous Golden House of Nero on the site now covered by the Baths of Titus, the Colosseum and the Basilica of Maxentius, very little remains.

The villa of Hadrian at Tivoli, begun about A.D. 123, was another sumptuous imperial residence with parks and gardens on a large scale. There are remains of great brick and concrete structures and the unevenness of the site necessitated large terraces and flights of steps. All the buildings are Roman in style and method of construction, though with Greek names.

The palace of Diocletian at Spalato (Split), to which he retired on his abdication in A.D. 305, combined a palace with a fortress and was truly monumental. It consisted of an immense rectangle surrounded on three sides with walls guarded by towers and on the fourth, to the south, protected by the sea. The palace itself was on the south side with a great gallery 520 ft. long with 51 windows overlooking the sea.

The word villa pertains to an estate, complete with house, grounds and subsidiary buildings. There are very few remains of Roman villas; our chief authority is Pliny, who gave a detailed description of his Laurentine villa. Hadrian's villa at Tivoli, an imperial residence, cannot be treated as typical.

In Roman architecture there were two types of houses, the *domus* and the *insula*. The *domus* consisted of suites of rooms grouped round a central hall or atrium, to which were often added further suites at the rear grouped round a colonnaded court or peristyle. The atrium, a rectangular room with an opening in the roof to the sky, and its adjoining rooms, was the peculiarly Roman element; the peristyle, or patio garden, was Greek or oriental. There were few windows on the street, light being obtained from the atrium or peristyle. The *domus*, as exemplified at Pompeii and Herculaneum (*qq.v.*) has long been regarded as the typical Roman house. In Rome itself, however, very few remains of the *domus* have come to light, the chief examples being the House of the Vestal Virgins on the forum and that of Livia on the Palatine.

From Latin writers it has long been known that there were in Rome great blocks of flats or tenements to which the term *insulae* was applied. Excavations at Ostia (*q.v.*) have revealed the design of these blocks. Planned on three or four floors with strict regard to economy of space they depended on light from the exterior, as well as from a central court. Independent apartments had separate entrances with direct access to the street. Since Ostia was a typical town of the 1st and 2nd centuries A.D. and was almost a suburb of Rome itself, it is supposed that *insulae* at Rome would present similar features. The street front of either *domus* or *insula* might be lined with shops. (*See* also RESIDENTIAL ARCHITECTURE.)

Town Planning.—Vitruvius clearly indicated that the Romans were keenly aware of the fundamentals of town planning, *i.e.*, the location of the city and its parts in terms of necessities, climate, functions and the like. When a new town was established such considerations were energetically examined.

A characteristic Roman plan, either inherited from early Italic towns or developed in the discipline of army camp engineering, was used. The over-all plan was square, with main avenues bisecting the sides and intersecting at the centre. The rest of the streets were in checkerboard grid.

At or near the centre was the forum; theatres, baths and other structures were located according to the site.

Long-established communities, which had developed by accretion rather than by plan, were often gradually brought, under Roman influence, within some approximation of this scheme, sometimes with considerable subtlety. Often, however, as in Rome itself, the scale and topography prevented the achievement of any fully logical order. In general, colonnades lined the important streets; water was conveyed to spectacular ornamental fountains or to practical neighbourhood basins from reservoirs fed by aqueducts (in some climates cisterns were necessary); many large sewers collected waste water from the street if not from private homes; also building codes were devised and enforced.

The layout of a whole town can be most easily seen in some of the towns in north Africa (*e.g.*, Timgad, Tebessa, Thuburbo Maius), where there has been little or no subsequent building to modify the original lines of the plan. (*See* also CITY PLANNING.)

ROMAN ART. There are at least five different ways in which Roman art can be defined: (1) The term might be restricted to works produced in or near Rome itself, which reflect specifically the national life and traditions of the city or the exploits of its citizens and rulers. (2) "Roman art" and "art in Rome" might be treated as convertible terms, including all imported works which mirror the effect of foreign contacts and ever-widening horizons on thought and taste in the metropolis. (3) The phrase might be extended to cover works of art that were made in, or imported into, Italy as united under Roman hegemony. (4) The phrase might be stretched to denote all works of art produced in, or brought into, the predominantly Latin-speaking countries of the western Roman empire. (5) "Roman art" may mean nothing less than the artistic output of the entire world dominated by ancient Rome. The art of the Greek-speaking provinces may justly be described as "east Roman," where existing Hellenistic traditions not merely survived conquest by Rome but gained fresh vigour and scope through incorporation into its system. It is in this fifth and widest sense that the term "Roman art" will be used in this article.

As regards chronology, "Roman" is taken as covering a period extending to *c.* A.D. 500; in respect of content, the word includes works of Jewish and Christian subject matter, indistinguishable in style from their pagan contemporaries and often borrowing some of their motives.

I. INTRODUCTION

The Romans themselves did not, it seems, have an innate and spontaneous capacity for art. Such works of art as were made in, or imported into, Rome during the periods of the monarchy and the early republic were produced almost certainly by Greek and Hellenized Etruscan artists, or by their imitators from the cities of central Latium; while throughout the later republican and the imperial epochs all the leading masters at least and many of the lesser craftsmen had Greek names and were Greek, or at any rate Greek-speaking, by extraction. References in ancient literature and the signatures of artists preserved in inscriptions leave no doubt on this point. According to tradition, the earliest image of a god made in Rome dated from the 6th century B.C. period of Etruscan domination and was the work of Vulca of Veii. The magnificent terra-cotta statue of Apollo found at Veii may give some notion of its character, while the celebrated bronze figure of the wolf in the Conservatori museum, Rome, is generally assigned to the same Veientine school. In the 5th, 4th and 3rd centuries, when Etruscan influence on Rome was declining and Rome's dominion was spreading through the Italian peninsula, contacts with Greek art were no longer chiefly mediated via Etruria, but were made directly through Campania and Magna Graecia; the paintings and the "idealizing" statues of gods and worthies that are mentioned in literature as executed in the capital during this period were clearly the works of visiting or immigrant Greek artists. The plundering of Syracuse and Tarentum at the end of the 3rd century marked the beginning of that flow of Greek art treasures into Rome which continued for several centuries and played a leading role in the aesthetic education of the citizens.

It was therefore to Greek artists that the Romans turned when, in the course of the 3rd century, they first apparently became aware of the potentialities of works of art for the visual expression of their own political, social and religious life and history. Greeks designed the dies for the silver coinage that Rome inaugurated in 269 to circulate through Italy, with types that displayed an ever-increasing richness and variety of style and content, particularly during the later 2nd and 1st centuries B.C., until the close of the republican epoch. Six documentary paintings depicting events from Roman history between 264 and 168 are known from literary sources. These events were, for the most part, military victories; the pictures themselves were ephemeral affairs shown at triumphs and on other public occasions to the Roman populace; and the artists who produced them were very probably Greeks, since in 168 L. Aemilius Paulus, the victor at Pydna, employed Metrodorus, a painter from Athens, to execute the topical pictures exhibited in Rome for his Macedonian triumph, and Demetrius, an Alexandrian "place painter," was in Rome in 164. The fragment of a historical wall painting with scenes from the Samnite wars, found in a family tomb on the Esquiline, probably dating from the 3rd century B.C. (in the Conservatori museum), may give some idea of the nature of these early triumphal pictures. Literature shows that by the middle of the 2nd century B.C. the Roman forum was thronged with honorific statues of Roman magistrates which, although none of them has survived, may be assumed to have been carved or cast by Greeks, since no native Roman school of sculptors of that time is known. And it is significant that the earliest account of Roman realistic portraits of private individuals is that contained in Polybius' description of the ancestral *imagines* ("masks") displayed and worn at patrician funerals—a description written about the middle of the 2nd century B.C., when the tide of Greek artistic influences was sweeping into Rome and Italy from countries east of the Adriatic, where a highly realistic late-Hellenistic portrait art, that sometimes depicted Roman or Italian subjects, had already blossomed.

The first appearance of the three art forms that expressed the Roman spirit most eloquently can be traced back to the Hellenistic age. These forms are realistic or veristic portraiture, in which every line, crease and wrinkle, and even blemishes were ruthlessly chronicled; the continuous, or "film," style in narrative art of all types; and the three-dimensional rendering of atmosphere, depth and perspective in relief work and painting. Of these three art forms there is no evidence in the early art of pre-Hellenistic central Italy, and it would be safe to guess that if Rome had not met them in the homelands of Greek art it would never have evolved them in its great art of imperial times. But Rome's own contributions to art, if of a different order, were vitally important. Its historical aims and achievements furnished late-Hellenistic artists with a new setting and centre, new subjects, new stimuli, a new purpose and a new dignity. Rome provided the external circumstances that enabled the sculptors, painters and other craftsmen to exploit on a much more extensive scale than before artistic movements initiated in the Hellenistic world, and Rome became a great new patron of art and a great new wellspring of inspiration and ideas. Thus Roman art is the child of the marriage of two traditions—one, the Hellenistic art tradition and the sculptural branch of that tradition in particular, the other, the political, social, religious and psychological tradition of Rome.

II. SCULPTURE

1. Last Century of the Republic.—The ancestral *imagines*, or funerary masks, made of wax or terra cotta, had become extremely individualized and realistic by the middle of the 2nd century B.C. The source of this realism is in the impact on Rome of late-Hellenistic veristic iconography; although this use of masks was rooted in ancient Roman social and religious practice, there is no basis for the statement that the Romans and Etruscans had, from early times, been in the habit of producing death masks proper, cast directly from the features of the dead. It was undoubtedly their funerary customs that predisposed the Romans to a taste for portraits. But it was not until *c.* 100 B.C. that realistic portraiture, as an art in its own right, appeared in Rome as a sudden flowering, and to that time belong the first beginnings of the highly realistic and veristic heads, busts and statues of contemporary Romans, in marble, stone or bronze, that have actually survived. The coin portraits of public men, whose names and dates are recorded, greatly assist in determining the chronological sequence of the large-scale likenesses, the earliest of which can be attributed to the period of Sulla. The veristic style reached its climax in the stark, dry, linear iconographic manner of *c.* 75–65 B.C., which expressed to perfection current notions of the traditional Roman virtues; of this manner the marble head of an elderly veiled man in the Vatican is an outstanding illustration. After that, an admiration for the earlier phases of Greek art came into fashion in the west, and verism was toned down at the higher social levels by a revival of mid-Hellenistic pathos and even by a classicizing trend that was to stamp itself upon Augustan portraits. Meantime, in sepulchral custom, the ancestral bust had become an alternative to the ancestral mask, a development exemplified in a togate marble statue of a man carrying two such busts in the Museo Capitolino Nuovo; while the portrait busts and figures on the numerous stone and marble grave *stelai*, characteristic of the late-republican epoch, proclaim the persistence of veris-

tic tastes in middle-class and humbler circles. Furthermore, there are some 1st-century B.C. portraits which suggest that the making of death masks proper (a sophisticated and essentially nonprimitive idea) was occasionally practised at this time. None of the vividly veristic Etruscan portraits, such as the bronze orator (*Arringatore*) at Florence and the terra-cotta married pair on the lid of a well-known ash chest at Volterra, is earlier than *c.* 100 B.C.; works of that type must be reckoned as provincial imitations of the new metropolitan, 1st-century B.C. portrait style.

There are no narrative reliefs from Rome that can confidently be assigned to a pre-1st-century B.C. period. The only definitely dated 2nd-century B.C. relief depicting an episode from contemporary Roman history, the frieze with the battle of Pydna on L. Aemilius Paulus' victory monument at Delphi, was worked in 168 in Greece. The most familiar republican example of this form of art as practised in the west is the frieze decoration, partly in the Louvre, Paris, and partly at Munich, from the so-called "Altar of Ahenobarbus," which has been shown to have no sure connection either with an altar or with any of the Ahenobarbi. The Louvre section gives a matter-of-fact and accurate representation of the Roman census ceremonies, while the Munich section depicts a marine procession of Neptune and Amphitrite with their train. Assuming that the two scenes belonged to the same monument, as the identity of their dimensions and material suggests, the most attractive theory of them is that they adorned the temple of the nymphs in the Campus Martius, when it was restored after its burning by Clodius in 57 B.C. That temple was the *archivium* of the census, while the nymphs were equated with the nereids and associated with Neptune; this would be an early and striking instance of that juxtaposition of Hellenistic and Roman motives, of human and divine persons and of mythology and history which was to characterize imperial state reliefs throughout their development. Fragments of a marble frieze, presenting successive scenes from Roman legendary history, were recovered from the Basilica Aemilia in the Roman forum and reconstructed before World War II. The subjects include the building of a city, probably of Rome itself, the rape of the Sabine women and the punishment of Tarpeia, and although there is no evidence for determining its date with certainty, the frieze could have been carved for the basilica's rebuilding between 54 and 34 B.C. Funerary narrative sculpture of the late republic is exemplified in the monument of the Julii at St. Rémy (Glanum), France. The base of this structure carries four great reliefs with battle and hunt scenes that allude, not only to the mundane prowess of the family, but also to the "other-worldly" victory of the souls of the departed over death and evil, since figures of the deceased, accompanied by personifications of death and victory, merge into one of the battle scenes. It is possible that these highly pictorial reliefs were partly based on lost Hellenistic monumental paintings. Southern Gaul had direct connections with Greek lands east of the Adriatic.

2. Augustan Age.—The hallmark of the portraits of Augustus is a naturalistic classicism. The rendering of his features and of the forking of his hair above the brow is individual. But the emperor is consistently idealized and never shown as elderly or aging. The marble statue from Livia's villa at Prima Porta (in the Vatican), which presents him as addressing, as it were, the whole empire, is the work of a fine Greek artist who, while adopting the pose and proportions of a classical Hellenic statue, understood completely what Augustus meant to Rome. On the ornate cuirass the princeps' aims and achievements are recorded symbolically in a series of figure groups, among which that of the restoration of the Roman standards by a Parthian to Mars occupies the central place. A marble portrait statue found on the Via Labicana represents the emperor as heavily draped, veiled and in the act of sacrificing as Pontifex Maximus; while a bronze head from Meroe in the Sudan (in the British museum, London), the work of a Greco-Egyptian portraitist, depicts him as a Hellenistic king. Of the female portraits of the period, one of the most charming is the green basalt head (in the Louvre) of the emperor's sister, Octavia, with the hair dressed in a puff above the brow and gathered into a bun behind—a popular coiffure in early Augustan times. The noblest, in many respects, of all the Roman public monuments that were adorned with sculpture is the Ara Pacis Augustae, founded in 13 B.C. and dedicated four years later. It stood in the Campus Martius and has been restored, with different orientation, not far from its original site; and in the harmonious blending, on its reliefs of Luna marble, of contemporary history, legend and personification, of figure scenes and decorative floral motives, it set a standard of distinction which no later work outrivalled. The altar proper was contained within a walled enclosure, measuring about $11\frac{1}{2}$ by $10\frac{1}{2}$ m., with entrances on east and west. On the upper part of the external faces of the south and north precinct walls ran a frieze representing the actual procession of Augustus and members of his family, of lictors, priests, magistrates and of the Roman people on the altar's foundation day (July 4, 13 B.C.) to its chosen site, where sacrifice was offered in thanksgiving for the emperor's recent return to Rome from the provinces. On either side of the western entrance were Augustus' prototype Aeneas sacrificing on his "home-coming" to the promised land of Italy and, since Augustus was also hailed as Rome's second founder, the suckling of the twins, Romulus and Remus, by the she-wolf. The eastern entrance was flanked by the personification of Italia with children on her knees, and by that of Roma. On the exterior of the walls, beneath all these figure scenes, was a magnificent dado filled with a naturalistic pattern of acanthus, vine and ivy, perhaps the translation into marble of a gorgeous carpet or tapestry used in the ceremony; while the swags of fruit and flowers that decked the interior faces of the precinct walls may represent real swags that were hung on the temporary wooden altar erected for the foundation sacrifice. The procession was continued in a much smaller frieze on the inner altar, from which figures of the vestal virgins and of the sacrificial victims and their attendants have been preserved. Delightful studies of imperial and other children and such homely incidents as conversations between persons taking part in the procession introduce an element of intimacy, informality and even humour into this solemn act of public worship. The Ara Pacis in fact sums up all that was best in the new Augustan order—peace, serenity, dignity without pompousness, moderation and absence of ostentation, love of children and delight in nature. The style of the altar's floral decoration strongly suggests that the sculptors who carved it were Greeks from Pergamum.

3. Julio-Claudian Period.—The somewhat cold, precise and academic portraits of Tiberius and Gaius show little further development, but it was probably from her son's principate that the finest of Livia's monumental portraits date. A seated statue of the empress, found at Paestum with a seated figure of Tiberius (in Madrid), shows her with hair simply waved from a central parting, an aquiline nose and the smooth brow and rounded cheeks of quite a young woman, although she was 72 when her son succeeded. The likeness of Antonia, Augustus' niece, is known from posthumous portraits dating from the reign of Claudius. These show her with a coiffure even simpler than Livia's and sometimes wearing the *tutulus* ("woolen fillet") appropriate to her office of priestess of Divus Augustus, as in the case of her colossal portrait head, the so-called "Juno Ludovisi," in the Roman National museum. Portraits of Agrippina I, of Agrippina II, who again occasionally wears the *tutulus* as priestess of Divus Claudius, and of the latter's rival Messallina display more elaborate hair styles. In Claudius' portraits fine, plastic modeling is combined with a realistic rendering of the subject's angular nose, sagging cheeks, clumsy neck and double chin; while those of Nero reveal an exuberant, idealizing treatment that matches his philhellenic interests. Of historical sculpture of this period relatively little has survived. Fragments of processional and sacrificial scenes, somewhat reminiscent of the Ara Pacis carvings (walled up in the Villa Medici on the Pincio) may have come from the Ara Pietatis Augustae which Claudius dedicated in A.D. 43. The "Jupiter-Column" set up in Nero's honour at Mainz (Mogontiacum) in Roman Germany, with figures of gods and personifications carved in relief on its base and shaft, is the only existing public monument which can be connected with that bizarre ruler.

4. Flavian Period.—In Vespasian's portraits something of

the old, dry, relentless verism returned. This can be observed in his striking likeness on one of the two historical reliefs that were unearthed in Rome near the Palazzo della Cancelleria just before World War II. A similarly sketchy and impressionistic handling of the hair is found on Titus' portraits, whereas Domitian affected a more pictorial hairdo in imitation of the coiffure introduced by Nero. Still more picturesque are the female hair styles of the time, which display piles of corkscrew ringlets or of tight, round curls. The Cancelleria reliefs date from the close of Domitian's reign and depict respectively Vespasian's *adventus* and reception in Rome in A.D. 70 and Domitian's *profectio,* under the aegis of Mars, Minerva and Virtus, for one of his northern wars. They are worked in a two-dimensional, academic, classicizing style that is in marked contrast with the vivid, three-dimensional rendering of space and depth with brilliant interplay of light and shade on the panels of the arch of Titus in the Roman forum. Those familiar reliefs, which present two excerpts from Titus' Jewish triumph, were carved in the early 80s. The late-Domitianic classicizing manner appears again in the frieze of the Forum Transitorium, which Nerva completed. This conflict of relief styles within the Flavian period is but one illustration of the ceaseless, unpredictable ebb and flow of different aesthetic principles throughout the history of imperial art.

5. Age of Trajan.—In portraits of Trajan the deepening of the bust, already seen in the later Flavian period, was carried a stage further; there is a new fluidity in the molding of the face; in the hair, which is plastered down across the brow, there is a partial revival of the late republican linear style. Aesthetically, one of the finest known likenesses of the emperor is a marble head in the Ostia museum; while on his monumental column there is a series of less idealized and probably more faithful renderings of his features. The coiffures of Trajanic ladies are, if anything, even more elaborate and extravagant than those of their Flavian predecessors.

The reliefs of Trajan's column, illustrating the two Dacian wars of 101–102 and 105–106 and winding up the shaft in a spiral band of Parian marble, one metre wide, is generally recognized to be the classic example of the continuous method of narration in Roman art. The scenes develop like a film, merging into one another and interlocking without any lines of demarcation between them, apart from an occasional tree that serves to punctuate the flowing text; while Trajan appears again and again in different situations, activities and costumes. A statuesque figure of Victory separates the histories of the two wars. There are 23 spirals and about 2,500 figures. But a high level of technical accomplishment is maintained throughout, and the interest and excitement of the theme never flag. Since the figures of men and animals had to be distinguished from a distance, they are inevitably overlarge in proportion to their landscape and architectural settings; and in order to avoid awkward empty spaces along the upper edges of the band and to preserve an allover, even, tapestrylike effect, the background figures in the scenes are reared in bird's-eye-view perspective above the heads of those in the foreground. These carvings must be visualized as once brightly painted, with weapons and horse trappings added in metal. The sources of the scenes were probably wartime sketches made by army draftsmen at the front, but the fusing together of those isolated pictures into a single scroll was the work of a single master artist, perhaps Apollodorus of Damascus, who designed the whole complex of Trajan's forum, basilica and column. The interior of the shaft contains a spiral staircase and the column, dedicated in 113, was intended primarily as a lookout post for viewing Trajan's architectural achievements—his forum and its adjacent markets, to accommodate which he sliced away the slope of the Quirinal hill; secondly, as a war memorial, when the relief bands were added and an eagle was to top the capital; and thirdly, as Trajan's future tomb, crowned by his statue (which was replaced by that of St. Peter) and containing the funerary chamber for his and his consort's ash urns.

To the last years of Trajan's reign or to the early years of that of his successor should be attributed the four horizontal panels that adorn the main passageway and the attic ends of the arch of Constantine. If fitted together they would form a continuous frieze of three main scenes which are, from left to right, an imperial *adventus,* a battle and the presentation to the emperor of prisoners and the severed heads of captives by Roman soldiers. The fact that the enemy is clearly Dacian, that the Roman soldiers are all clean-shaven and that the lictors on the left wear the Trajanic hair style, combined with the close resemblances between this frieze and that of the column, leaves no room for doubt that these sculptures were made between *c.* 115 and 120, perhaps for the temple of Divus Trajanus and Diva Plotina which was erected by Hadrian just to the north of the column. The presence on this frieze of chain-mail corselets, never seen on Trajan's column, seems to indicate that that type of armour, so common under the Antonines, first came into use in late-Trajanic or early-Hadrianic times. These reliefs depict, not realistic fighting, as do those of the column, but a kind of ideal or dramatized warfare, with the emperor himself participating in the mêlée and the soldiers wearing plumed and richly embossed parade helmets; the scenes melt into one another with total disregard of spatial and temporal logic. A third example of Trajanic monumental sculpture is the relief decoration of the arch at Beneventum, spanning the new Via Trajana and completely covered on passageway, pylons and attics with pictorial slabs, the subjects of which are arranged to carry out a carefully balanced and nicely calculated order of ideas. Those on the side facing the city and on one wall of the passageway present themes from Trajan's policy and work for Rome and Italy; those on the side toward the country and on the other wall of the passageway allude to his achievements abroad. With two exceptions, where a pair of scenes forms a single picture, each panel is a self-contained unit, and these reliefs already show something of the classicizing, two-dimensional character of Hadrianic work. Indeed, it seems likely that, although the arch itself was either decreed or dedicated in 114–115, some of the panels in which Hadrian is given a peculiar prominence were not carved until the early years of the latter's principate. The frieze of the great, circular Tropaeum Trajani, set up in the Dobruja (Rumania) to commemorate the Dacian victories, contains a series of metopes carved with figure scenes in an unbelievably naïve, flat and linear style that betrays the hands of army artists of provincial origin.

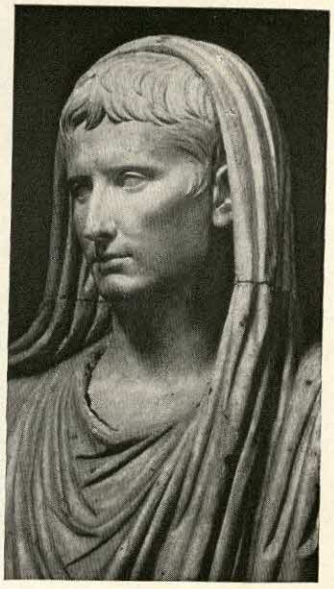
6. Age of Hadrian.—In the iconography of the age of Hadrian, certain Hellenizing features, the wearing of a short Greek beard by the males and the adoption by the females of a simple, classicizing coiffure, are harmonized with new experiments. The depth of the bust increases, there is greater plasticity in the modeling of the face, the men's curly hair and beards are pictorially treated and the irises and pupils of the eyes are marked in. Many marble portraits of the emperor survive from all over the empire, but of his likenesses in bronze only one is extant—the colossal head recovered from the river Thames in London, torn from a statue erected in the Roman city and probably the work of a good Gaulish sculptor. The portrait statues of Hadrian's Bithynian favourite, Antinous, reveal a conscious return in the pose and proportions of the body to classical Greek standards, combined with a new emotionalism and sensuousness in the rendering of the head. The exquisite relief in Rome of Antinous-Silvanus is signed in Greek by Antonianus of Aphrodisias in Asia Minor.

The monumental reliefs of Hadrian's day cannot vie with those of his predecessor's. The most interesting and perhaps the earliest of them are the two familiar horizontal slabs once exposed in the Roman forum but later transported to the shelter of the *curia.* Both carry on one side similar figures of the victims for the Suovetaurilia sacrifice and different historical scenes on the other side, in the one case, Hadrian doling out the *alimenta* ("poor relief") to Roman citizens in the presence of a statuary group of Trajan and Italia with children, in the other case, the burning of debt registers. At one end of each of these scenes is carved a figure on a base of Marsyas, whose statue in the forum may once have been in part enclosed by the panels. In the background of both historical pictures are carved in low relief various buildings in the Roman forum that can be identified. The two scenes display the characteristically Hadrianic two-dimensional style, as

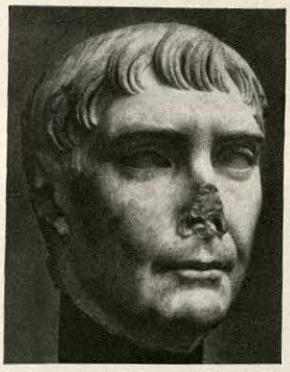
Woman of the Flavian period (last half of 1st century A.D.); marble. Capitoline museum, Rome

Constantine I (288?–337); marble. Conservatori museum, Rome

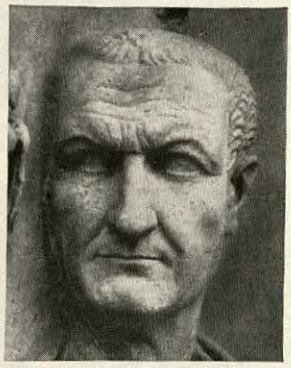
Portrait in death-mask style of 1st century B.C.; marble. Archaeological museum, Turin



Augustus as *Pontifex Maximus;* head of a marble statue. National museum, Rome

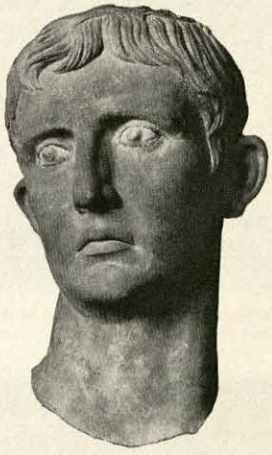


Trajan (53–117); marble. Ostia museum



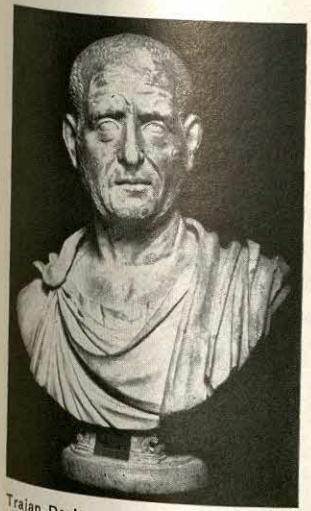
Vespasian (9–79); from a marble Domitianic relief. Vatican museum, Rome

Hadrian (76–138); bronze found in the Thames river, London. British museum



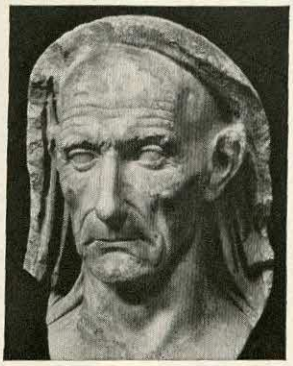
Augustus; bronze found at Meroe, Sudan. British museum

An emperor of the 4th or 5th century A.D.; bronze. Near Church of S. Sepolcro, Barletta



Trajan Decius; marble, about 249–53. Capitoline museum, Rome

Agrippina the Younger (16–59); marble. Ny Carlsberg Glyptotek, Copenhagen



Head of a priest; marble, about 75–65 B.C. Vatican museum, Rome

Commodus (161–192) represented as Hercules; marble. Conservatori museum, Rome

do also three large panels in the Conservatori museum, with the emperor's head restored and depicting an imperial *adventus*, an *adlocutio* and an apotheosis respectively—somewhat rigid, academic works. The eight medallions gracing the arch of Constantine give pleasantly composed and lively, if Hellenizing, pictures of sacrifice and hunting, in some of which can be recognized Antinous accompanying the emperor, whose portraits have been recut as likenesses of Constantine the Great and of his colleague Licinius. Finally, the historical reliefs found at Ephesus (now in Vienna)—one of the very few examples of provincial state reliefs that have survived—may be claimed as late-Hadrianic (not as of the period of Marcus Aurelius, to which many critics have assigned them). The most important of these Ephesian carvings shows a group of four imperial personages, who can be identified as Hadrian, his heir Antoninus Pius and the latter's adopted sons, Marcus Aurelius and Lucius Verus. The panels would, then, date from between Pius' adoption by Hadrian in Feb. 138 and the latter's death in the July of that year. Pius had been a popular proconsul of Asia, and the unorthodox representation of him in this relief as Hadrian's equal and colleague, unthinkable in Rome, could have passed muster on a provincial monument. The most imposing of the other panels of the series carries an imperial apotheosis—Divus Trajanus in full military costume mounting the chariot of the sun-god for his journey heavenward. Some fragmentary battle scenes may be excerpts from Trajan's Dacian or eastern wars, reflecting glory on his adopted son, Hadrian, and succeeding generations. In Rome and Italy during the second quarter of the 2nd century inhumation began to supersede cremation as a method of disposing of the dead, and Hadrian's reign saw the beginnings of the long line of carved sarcophagi that constituted the most significant class of minor sculptures down to the close of the ancient Greco-Roman world.

7. Antonine and Severan Periods.—Portraits of Antonine imperial persons, of which the bronze equestrian figure of Marcus Aurelius on the Capitol and the great marble bust of Commodus-Hercules in the Conservatori museum are perhaps the most arresting examples, display a treatment of hair and beard, deeply undercut and drilled, that grew ever more pictorial and baroque as the 2nd century advanced. This produced an impression of nervous restlessness that contrasts with the still, satin smoothness of the facial surfaces, particularly in the iconography of Commodus. To all this picturesqueness Septimius Severus added yet another ornamental touch—the dangling, corkscrew forelocks of his patron deity, Sarapis. The female hair styles of the time are characterized, first by a coronal of plaits on top (Faustina I), next by rippling side waves and a small, neat bun at the nape of the neck (Faustina II, Lucilla) and then by stiff, artificial, "permanent" waving at the sides and a flat, spreading "pad" of hair behind (Crispina, Julia Domna).

Of the state reliefs of this epoch the earliest are on the base (in the Vatican) of the lost column set up in honour of Antoninus Pius and Faustina I. The front bears a dignified, classicizing scene of apotheosis: a powerfully built winged figure lifts the emperor and empress aloft, while two personifications, Roma and Campus Martius, witness their departure. On each side is a *decursio*, or military parade, in which the riders farthest from the spectator appear, not behind the foot soldiers, but high above their heads —a remarkable instance of the bird's-eye-view perspective carried to its logical conclusions. All the figures in these side scenes are disposed on projecting ledges, a device employed again about 20 years later on Marcus Aurelius' column. Eleven rectangular sculptured panels, similar to those on Trajan's arch at Beneventum but displaying greater crowding of figures, livelier movement and a pronounced effect of atmosphere and depth, depict official occasions and ceremonies in the career of Marcus. Three are in the Conservatori museum, the other eight are on the attics of the arch of Constantine. They may have been carved for two triumphal arches (a 12th panel being lost) or for some single monument. The contrast between the reliefs of Marcus' column, put up under Commodus, and those of its Trajanic predecessor measures the change of mood that the Roman world experienced during the course of the 2nd century. The diminished proportions of the squat, doll-like figures, their herding together in closely packed, undifferentiated masses, their angular, agitated gestures and the stress laid throughout on the horror and tragedy of war, suggest that the empire is facing an unknown future with diminished security and that man is at the mercy of some unaccountable power, of which the awe-inspiring winged, dripping figure, brooding above the famous rainstorm episode, represents the supreme embodiment. Again, in the imperial *adlocutiones* that punctuate this frieze, where the emperor stands in a strictly frontal pose high above the heads of his audiences, can be seen the first attempts at externalizing in art the concept of the ruler as a transcendental being. The content of these spiral bands is Marcus' German wars of 173–175 and 177–180.

The spirit of the times is reflected no less vividly in the carved sarcophagi, with their crowded compositions, seething movement, brilliant highlights and deep wells of shadow. Their themes—familiar myths, battles, hunts, marriages, etc.—allude allegorically to death and the destiny of the soul hereafter. Meanwhile, the classicizing, statuesque tradition is maintained in the late 2nd- and early 3rd-century columned sarcophagi, originating in the workshops of Asia Minor but freely imported into, and sometimes imitated in, Rome and Italy. On such pieces single figures, or small groups of figures, occupy the niches between the colonnettes. Among the most impressive examples is the great sarcophagus at Melfi, in Apulia, Italy, with a couch-shaped lid, on which the figure of a girl lies prostrate in the sleep of death.

The novel features that have been noted in the reliefs of the Marcus column were worked out more completely in those of the official monuments set up in Septimius Severus' honour, both in Rome and abroad. The three-way arch that stands at the northern end of the Roman forum was erected in 203 to commemorate both the emperor's Parthian victories and his *decennalia* (the conclusion of his first ten years of rule). Large-scale flying Victories and groups of Roman soldiers and Parthian captives occupy respectively the spandrels above the central passage and the column bases on both faces of the arch; while above both the side passages on either face are scenes from the campaigns. There are masses of small, crowded figures, arranged in superimposed registers in laterally spreading pictures, which in the extensive use of bird's-eye-view perspective recall the spiral bands of the Trajan and Marcus columns. They, too, were doubtless based on military artists' sketches and may represent permanent versions of the public paintings of the eastern wars which, so Herodian says, Septimius exhibited in Rome. The small but richly ornamented Porta Argentariorum, dedicated in the Velabrum in 204 to Septimius and his family by the bankers and wholesale cattle dealers of the capital, carries two major sculptured panels, one of which shows Septimius and his Syrian wife, Julia Domna, sacrificing at a tripod. This composition is strictly two-dimensional and the figures are arranged in stiff, hieratic, frontal poses. They express no interest in the rite which they profess to be performing, but gaze out into the distance as though in search of the spectators' homage. The figure of Septimius' younger son Geta which was once in the group, was removed after his murder by his elder brother Caracalla who now appears alone in the second major panel, from which the figures of his wife Plautilla and of her father Plautianus were likewise obliterated at the time of their disgrace and deaths. But of all Septimius' state reliefs the most interesting are those found fallen from the four-way arch that was set up in his birthplace, Leptis Magna in Tripolitania, to commemorate his visit to that city *c.* 203. On the attics were four long, friezelike scenes, of which the most impressive depicts the triumphal entry into the town of the frontally-posed emperor and his sons. The other attic panels, one of which portrays the proclamation of Caracalla as his father's colleague (*dextrarum iunctio*) in the presence of Julia Domna and representatives of Leptis, and most of the minor panels from the inner faces of the piers, refer to ceremonies held at Leptis on the same occasion. But one pier carried a great vertical picture of the siege of an oriental city, with the defenders at the top and the attackers climbing up, as it were, from below in mounting series—a magnificent example of the bird's-eye viewpoint. Flying Victories filled the spandrels

and on the outer faces of the piers were groups of strangely elongated captives and flat pilasters carved from head to foot with peopled vines scrolls, deeply undercut and drilled—a very distinctive type of design, which recurs on the pilasters that are grouped on either side of the apses of the Severan basilica at Leptis. The handsome inhabited floral scrolls, on pilasters, and the heads carved on brackets, that adorned the Hadrianic baths at Aphrodisias in Caria, are so remarkably similar to the scrolls from the arch and basilica and to the heads from the Severan forum at Leptis, that there can be little doubt that sculptors from Asia Minor were imported to carve these great Severan buildings in the African emperor's native city.

8. Third and Fourth Centuries.—A new tension between naturalism and schematization marks the history of late-antique portraiture. In likenesses of Alexander Severus (222–235) the facial planes are simplified, while all the tumbling curls of the 2nd-century baroque have been banished in favour of a skullcap treatment of the hair and sheathlike rendering of the beard. Toward the middle of the 3rd century, under Philip the Arabian (244–249) and Decius (249–251), this clipped technique in hair and beard is combined with a return to something of the old, ruthless realism in the depicting of facial furrows, creases and wrinkles. For a time Gallienus (253–268) reinstated the baroque curls and emotional expression, but in the later decades of the century the schematic handling of hair, beards and features reappears. Finally, in the clean-shaven heads of Constantine the Great and his successors of the 4th and early 5th centuries the conception of a portrait as an architectonic structure comes to stay and the naturalistic, representational art of the Greco-Roman world is exchanged for the hieratic, transcendental style that was the hallmark of Byzantine and medieval iconography. The hair is combed forward on the brow in rigid, striated locks, and the eyes are unnaturally enlarged and isolated from the other features as the channels through which the soul communicates with a higher power. The face is now so formalized that the identification of any given portrait becomes a problem. The colossal bronze emperor at Barletta, for example, has been given the names of several different rulers of the late 4th and early 5th centuries. Throughout these centuries the favourite female coiffure shows a plait or twisted coil of hair carried across the back and top of the head from neck to crown, while under Constantine there was a brief revival of the two Faustinas' styles.

Throughout the 3rd and 4th centuries carved sarcophagi carry on the story of relief work. Aesthetically, the most notable 3rd-century example is the allover tapestrylike battle piece (in the Ludovisi collection in the Roman National museum) probably made for Decius' son Hostilian. One of the main interests of this field of art, as regards content, lies in the Christian sarcophagi, which are in style and in technique indistinguishable from their pagan counterparts. During the 3rd century their themes are still allusive and symbolic, but with the peace of the church under Constantine Biblical subjects of a very varied range are openly depicted. Of 3rd-century state reliefs in Rome virtually nothing has survived. The narrow historical friezes that were carved *de novo* for the arch of Constantine, completed for his *decennalia* celebrations in 315, show dwarfish, dumpy, niggling figures. Both these reliefs and those of the slightly earlier arch of Galerius at Salonika look as though they had been worked by artists whose experience had been confined to the production of small-scale sculptures. The last examples of Roman carving are the reliefs on the base of the obelisk of Theodosius in the Hippodrome at Constantinople, where the emperor and members of his court, ranged in rigid, hieratic poses, watch the shows. No original portions are extant of the spiral relief bands that entwined the columns of Theodosius and Arcadius in Constantinople, in imitation of the Roman prototypes.

III. PAINTING AND MOSAICS

1. Wall Painting.—Evidence for painting in Rome and Latium before the 1st century B.C. is virtually confined to the fragment, described above, of a historical tomb painting from the Esquiline, to the literary accounts of triumphal pictures, already mentioned and to the record by ancient writers of the names of three painters each of whom worked in a temple—Fabius Pictor in the temple of Salus in Rome at the end of the 4th century; Pacuvius, the dramatist and a native of Brundisium, in the temple of Hercules in the Forum Boarium in Rome during the first half of the 2nd century; and Lycon, an Asiatic Greek, in the temple of Juno at Ardea in the late 3rd or early 2nd century. Of the nature of the work of these three artists no idea can be formed.

At Pompeii during the 2nd century B.C. the interior walls of private houses were decorated in the so-called "masonry" or "incrustation" style; *i.e.*, by the imitation in painted stucco of veneers of *crustae* ("slabs") of coloured marbles. But in the second half of the 1st century B.C. there suddenly appeared in Rome and in the Campanian cities a brilliant series of domestic mural paintings of the so-called "second style," the aim of which was to deny the walls as solid surfaces confining the room space. This was sometimes done by covering the whole area of the walls with elaborate landscapes, in which depth, atmosphere and light are rendered in a highly pictorial, illusionistic manner. Such are the famous Odyssey paintings, found in a Roman house on the Esquiline (now in the Vatican), consisting of a continuous flow of episodes that unfold, filmlike, beyond a colonnade of pilasters, with vertical, bird's-eye-view perspective and the human figures strictly subordinated to their settings. At other times there appears the representation of a great park or garden, filled with trees, shrubs, flowers and birds, with no pilasters in the foreground to interrupt the prospect and with no human figures to distract attention, as in the case of the room from Livia's villa at Prima Porta (transferred to the Roman National museum). The paintings in this style are so highly developed that it seems unlikely that they suddenly sprang into being at this time in Rome and Italy without any Hellenistic precursors. Nevertheless, no late-Hellenistic paintings at all like them have come to light in Greek lands, and they constitute what is perhaps the most original and interesting western Roman-age contribution to ancient art. Possibly Hellenistic painted stage sets were, in part at least, their models; Vitruvius mentions three types of back scenes, tragic, comic and satyric, which seem to be reflected in the paintings from a room in the Villa of Fannius Synistor (or of L. Herennius Florus) at Boscoreale near Pompeii. Again, the triumphal "place paintings" may have played a certain role in this development.

The celebrated frieze of life-size figures, depicting the Dionysiac initiation rites and prenuptial ordeals of a bride, in the so-called *triclinium* of the Villa of the Mysteries (or Villa Item) outside the Herculaneum gate of Pompeii, also belongs to the "second style." There the walls are denied by the device of substituting for them a narrow stage on which the ritual is carried out before a drop scene of continuous painted panels. But the commonest "second-style" paintings are known as architectural and show a threefold horizontal division of the wall into dado, central area and cornice, combined with a triple vertical scheme of design which consists of a large central panel (in the main, intermediate horizontal area), framed by flanking columns and a pediment, and of two smaller panels on either side. The central panel, and often the lateral panels as well, are views seen through windows that break through the walls and link the spectator with the world outside, as in the house of Augustus on the Palatine. In the "third style," which covers most of the Augustan period, the central panel picture on a wall is no longer thought of as a scene through a window, but as a real picture hung on or inserted into a screen, or woven into a tapestry, which partially conceals an architectural vista behind it. The columns, entablatures, etc., are completely unreal and so complicated that this form of the "second style" is sometimes dubbed ornate. The "fourth style," which runs from the close of the Augustan age to the destruction of the Campanian cities in A.D. 79, is less homogeneous than its predecessors and exhibits three main variants—first, a soberer, more realistic architectural design, but still with a central screen or tapestry partly covering a retreating vista; second, an architectural setout that imitates a *scaena* ("stage background"); and third, a method (sometimes known as "intricate") by which the whole surface of the wall is covered with a flat, white, neutral ground that is painted with an all-over, lattice-

like pattern of fantastic architectural elements, arabesques, grotesques, small figure motifs or small panels containing pictures. This third type of "fourth-style" painting came into vogue at Pompeii between the earthquake of A.D. 63 and the catastrophe of 79, and one of its most impressive exponents is the Golden House of Nero in Rome.

The subjects of the panel pictures of the "second," "third" and "fourth" styles are for the most part drawn from Greek mythology. Some of them recall the literary descriptions of famous classical Greek and Hellenistic paintings or show motifs which suggest that their originals were painted on the Greek mainland or in Asia Minor. It is certain that many masterpieces of Greek painting did make their way to Rome as the booty of Roman generals of republican days, and wall painters could have studied them at first hand. But often those artists must have had to rely only on sketches of the celebrated pictures, and it is not known how faithfully the Roman and Campanian murals reproduce the prototypes. Other panel pictures present scenes from contemporary religious ritual, while a few show themes from Roman legend. Frequently, in the case of the Greek mythological subjects and of those taken from rustic religious cult, the artist had produced landscape with figures, as in the Odyssey frescoes, not figures with landscape, as on Trajan's column. These late-republican and early-imperial set pieces are competently executed, remarkably vivid and extremely naturalistic. But, with a few exceptions, they reveal that the principles of a single vanishing point, on which all receding lines converge, and of unified lighting from a single source of illumination, either were not understood by the Roman-age painters, or did not interest them.

The flat, uniform background of the last phase of the "fourth style" remained a constant feature of mural painting in houses, tombs, temples and other religious shrines throughout the 2nd, 3rd and 4th centuries. The decoration which stands out against that ground takes the form of latticelike, allover floral, etc., patterns, as in many pagan tombs; of small groups of figures, or of figure panels, spread out at intervals across the field, as in the Christian catacombs of Rome; of a mixture of large human figures and extensive scenes with small-scale figures, as in the early 3rd-century Hypogeum of the Aurelii on the Viale Manzoni in Rome, the interesting painted content of which is Gnostic or crypto-Christian; of large scenes with relatively big figures, such as the group of marine deities in the 2nd-century Roman house under the church of SS. John and Paul on the Caelian, the late 2nd- or the early 3rd-century leopard hunt on the south wall of the *frigidarium* of the hunting baths at Leptis Magna, or the early 3rd-century Biblical scenes from the Christian baptistery at Doura-Europos on the river Euphrates. The walls of the main assembly room of the early 3rd-century synagogue in the last-mentioned city are covered with an exceptional series of great self-contained figure panels, arranged side by side in superimposed registers with no intervening tracts of empty background between them.

In the case of Roman tombs the cross- or barrel-vaulted ceilings, where preserved, carry out normally the painted decoration of the walls, showing either a latticelike scheme of small ornamental motives or a series of small, spaced-out, figured panel pictures. At Trier in 1945–46 were found the remains of a flat, coffered ceiling with panels of painted plaster from an early 4th-century imperial hall that was destroyed to make room for the first Christian basilica built on the site of the present cathedral. Large portions of eight painted panels are preserved. Four depict female busts, three of them nimbed, which may be either personifications or portraits of members of the royal family; while the other four show pairs of dancing or sporting cupids. As the skillful modeling and lively naturalism of these figures show, Roman painting could maintain a high level of achievement in late-antique times.

2. Floor Mosaics.—Few categories of works of Roman art show more surviving examples than that of mosaic pavements. *Opus tessellatum*, made of *tesserae* ("cubes") regularly disposed in geometric designs, and *opus sectile*, in which the floor consists of a polychrome intarsia of marble fragments, larger than *tesserae* and generally forming abstract or stylized floral patterns, cannot be discussed in detail here. But *opus vermiculatum*, where figure pictures and naturalistic floral compositions are produced by small and subtly shaped *tesserae*, is almost a branch of painting, in which stone or marble or, in later times, glass paste replace the liquid medium. This type of work appeared in Italy during the 2nd century B.C. and was directly inspired by such late-Hellenistic mosaics as those unearthed in the royal palace of the Attalids at Pergamum and in private houses on the island of Delos, and from Italy it spread rapidly through the empire. Sometimes these floor mosaics are large, self-contained, panel pictures, of which an early example, of the late 2nd, or early 1st, century B.C., is the well-known Alexander mosaic (in Naples) from the House of the Faun at Pompeii. It depicts the battle of Issus and probably represents fairly faithfully a late 4th-century monumental painting. This was the work of a master mosaicist, as were also many of the small mosaic pictures or *emblemata*, which were often mounted on marble or terra-cotta trays and transported, at first from east Mediterranean workshops to Italy, and later from Greek and Italian centres of production to the provinces, where they were inserted into surrounds of geometric patterns laid by inferior local craftsmen. The master mosaicists themselves often traveled far afield to execute *emblemata* or large designs on the spot, as their signatures testify. The subjects of mosaic pictures cover an extensive range—Greek myths (the most popular), Roman legends, Nilotic and other landscapes, scenes from natural history, portraits of famous characters, personifications, topics inspired by the games and shows, by the hunting field, by rural life and by religious ritual, and naturalistic running scrolls of acanthus, vine and ivy. A most remarkable discovery is that of the pavements in the 4th-century country villa near Piazza Armerina, Sicily. These form the largest continuous area of Roman mosaic floors known and include a vast scene, in a corridor 70 yd. long, of the hunting, capturing and transport of wild birds and beasts for display in the arena. The most important and the richest dated series of floor mosaics, running from the early 2nd to the 6th century, is that unearthed, mainly in private houses, at Antioch-on-the-Orontes in Syria. The floor mosaics of the 4th-century Christian basilica at Aquileia display an interesting mixture of Christian, pagan and neutral themes.

3. Wall and Vault Mosaics.—Wall and vault mosaics that have survived are relatively rare. The earliest and best-preserved examples are those adorning fountains in the courtyards of houses at Pompeii and Herculaneum. These show brilliant polychrome designs, with a lavish use of glass-paste *tesserae* and borders of natural shells. But in the House of Neptune and Amphitrite at Herculaneum most of one wall of the internal courtyard has been turned into a species of *nymphaeum*, with a central rounded niche flanked by two rectangular niches and the whole facade overlaid by an exquisite glass-paste mosaic depicting naturalistic vine sprays, hunting scenes and festoons of fruit and foliage. A curved fountain niche of late 2nd- or early 3rd-century date, found in a Mithraeum at Ostia (in the Lateran museum), bears a glass-paste mosaic figure of Silvanus, nimbed and equipped with pruning knife and dog, seen against a blue background. From Pompeii and Herculaneum there are a few mosaic panel pictures, mythological in content, that were set on walls; while part of a wall panel representing a harbour, found on the Quirinal, is in the Conservatori museum.

The number of pre-5th-century vault mosaics known to have survived has considerably increased. At Ostia the semidome and arch soffit of a large niche in the House of the Seven Sages are faced with polychrome mosaic worked in delicate and naturalistic plant designs. Somewhat fragmentary, but still impressive, mosaic figures—a nymph suckling a kid, a triton and a crocodile in a Nilotic landscape—appear in the semidome of the east plunge in the *frigidarium* of the hunting baths at Leptis Magna. In the mausoleum of the Julii in the necropolis beneath St. Peter's, Rome, are the earliest Christian vault and wall mosaics known, dating from about the middle of the 3rd century and worked in glass-paste *tesserae*. Their subjects are the divine angler, Jonah and the whale, the good shepherd and Christus-Helios in his chariot, with a great, spreading vine linking together the four pictures. All these are comparatively new finds, and there is quite a number

of lesser fragments of vault mosaics that cannot be described here. The familiar mosaic decoration on the vault of the circular ambulatory in the church of Sta. Costanza in Rome contains a curious mixture of subjects disposed in large, rectangular panels; these mosaics, once held to be an instance of the early Christian use of pagan or neutral art motifs, have been shown to belong to the late 3rd- or early 4th-century pagan shrine or mausoleum that the building originally was, before it was converted to Christian purposes. The 4th-century Christian mosaic from the apse of old St. Peter's in Rome, and the 5th-century Christian wall and vault mosaics at Ravenna and in the church of Sta. Maria Maggiore in Rome, while ranking as Roman, cannot be described here.

Finally, mention must be made of figured wall panels of brightly coloured *opus sectile,* such as that with a beast fight in the Ostia museum and those showing beast fights, Hylas and the nymphs and the decorative group of horsemen and a frontal chariot, which came from the 4th-century basilica of Junius Bassus on the Esquiline (in the Palazzo del Drago at the Quattro Fontane).

4. Painted Portraits.—Roman portrait painting comes but a short way behind portrait sculpture in excellence of execution and in its superbly realistic style. One of the earliest extant examples of this art is the group of Terentius Neo and his wife, from Pompeii (in the Naples museum). Both figures recall the celebrated mummy portraits from the Fayum in Egypt, painted in encaustic, the technique by which the colours were mixed with liquid wax and fixed by heat, and ranging in date from the Flavian period to the 3rd century. A circular portrait group of frontal figures painted on wood, probably in Egypt (now in Berlin), shows Septimius Severus, Julia Domna, Caracalla and Geta, the elder (so it seems) of the two boys having been subsequently washed out. Particularly attractive are the portraits of the gold-glass medallions which, in the exquisite refinement of their treatment, may be compared to modern miniatures. The medallion at Brescia, dating from the 4th century and carrying the portrait group of a mother with her boy and girl, is a veritable masterpiece; while some of the portraits of Christians in the same medium and found, for the most part, in the catacombs, continue the best traditions of Roman veristic iconography.

5. Book Illustration.—That book illustration existed in the late-Hellenistic world can be inferred from some of the so-called Megarian bowls, imitations in clay of gold or silver vessels and ranging from the 3rd century B.C. to the 1st century A.D. These often bear on their exteriors scenes in relief from literary texts which are sometimes accompanied by Greek quotations. They must, in part at least, have served as models for the Roman age artists, and this art is heard of in Rome comparatively early—the 700 pictures, for example, illustrating Varro's 15 books of *Imagines* and a portrait of Virgil prefixed to an edition of his poems. The miniatures in the famous codex of the *Iliad* in the Ambrosiana library, Milan, were probably painted at the end of the 5th or beginning of the 6th century, but reflect pictures of the 3rd, 2nd and even 1st century; as do also those of the codex of Virgil in the Vatican (No. 3225), written *c.* 400. The miniatures in the second great Virgilian illustrated codex in the Vatican (No. 3867 "Romanus"), written *c.* 500, are still Roman in spirit, if less classical in style; the tenacious influence of Graeco-Roman painting can be clearly traced in the illustrations to such early Byzantine books as the Vienna Dioscurides (written in 512), the Vienna Genesis (6th century) and the Joshua Roll (10th century). A most remarkable, if aesthetically crude, mid-4th-century mosaic pavement, found in a Romano-British villa at Low Ham, Somerset, and showing scenes from the first and fourth books of the *Aeneid,* undoubtedly reflects the illustrations in some Virgilian codex.

IV. STUCCO WORK

Of the minor forms of sculpture none is more attractive than the art of modeling, in relief or in the round, in fine, white stucco. Decorative stucco work was cheaper and easier to produce than carving in stone or marble, soft and delicate in texture and equally elegant whether left white or gaily painted. It was used at all levels of society, in public as well as in private buildings. In domestic architecture it was a useful alternative or accessory to painting; here it is sufficient to recall such examples as the pure white and exquisite vault decoration, showing ritual scenes with small-scale figures, of the late-republican or early-imperial house near the Villa Farnesina in Trastevere (in the Roman National museum); the handsome pairs of large white griffins, framed in acanthus scrolls against a vivid red ground, in the late republican House of the Griffins on the Palatine; and the frieze depicting the story of the *Iliad,* in white figures on a bright blue background, in the House of the Cryptoporticus or Homeric house at Pompeii. For the use of this technique in palaces the figure work in Domitian's villa at Castel Gandolfo in the Alban hills can be cited; it can be found on public buildings, in the Stabian and forum baths and in the temple of Isis at Pompeii; while the most lovely and extensive stucco relief work in a semiprivate shrine is that in the underground basilica near the Porta Maggiore, Rome, where the scenes all allude to the world beyond the grave, to the soul's journey to it and to its preparation for it in this life. Some of the best surviving stuccoes are in tombs—in the tomb of the Innocentii and the tomb of the Axe under the church of S. Sebastiano on the Via Appia; in the tomb of the Valerii and the tomb of the Pancratii on the Via Latina, in the latter of which stucco work is most attractively combined with painting in the flat; and in the tomb of the Valerii under St. Peter's, Rome, where the interior walls of both the main and subsidiary chambers are almost completely covered with recesses, niches and lunettes containing stucco figures. The whole effect is most impressive, and the Vatican tomb of the Valerii must be reckoned as a *locus classicus* for the study of this delightful and all too scantily represented branch of Roman art.

V. MINOR ARTS

1. Decorated Metalwork.—The Roman taste for costly silverware, with figured or floral relief decoration, is attested by the elder Pliny and by the numerous surviving pieces. Among the earliest-known examples in a Roman context is the *cantharus* ("goblet") with myrtle sprays, discovered at Alesia in one of Julius Caesar's siege trenches of 52 B.C. The treasure from Boscoreale containing 108 pieces (of which 102 are in the Louvre) and that of 118 pieces, which had been packed away in a strongroom in the House of Menander at Pompeii (now in the Naples museum), obviously antedate the disaster of A.D. 79. The former treasure contains two *scyphi* ("cups," in the Rothschild collection in Paris) with scenes from contemporary Augustan history. The latter comprises not only cylindrical cups and *canthari* of the early-imperial period, but also late-Hellenistic *scyphi,* perhaps dating from as early as the late 2nd century B.C., one pair being signed by Apelles. Probably belonging to the Augustan period are a number of the pieces in the two treasures found respectively at Berthouville, Normandy (in the Bibliothèque Nationale, Paris), and at Hildesheim, Germany (in Berlin), although the former hoard includes some objects that may well be later, while the latter also contains some earlier Hellenistic works; to the Augustan epoch should again probably be attributed the two *scyphi* that came to light at Hoby, near Copenhagen, signed by Cheirosophos and depicting the ransoming of Hector and the story of Philoctetes. A round *patera* ("dish") from Aquileia (in Vienna), portrays a Julio-Claudian emperor as the "new Triptolemus." Of the British museum silver pieces found in France, the Chatuzanges and Chaource treasures probably date from the 2nd century A.D.; whereas the Seasons bucket (*situla*) from Tourdan, near Vienne, often described as Augustan, and the treasure from Caubiac, near Toulouse, display the superficially naturalistic classicism combined with a certain clumsiness and faultiness in drawing that is the hallmark of 4th- and 5th-century Roman decorated metalwork. It is, indeed, to this late-antique period that some of the most spectacular and interesting extant silver pieces and hoards belong. As regards the single pieces, special mention should be made of the silver-gilt *patera* found at Parabiago, Italy (in the Antiquities department, Milan), with scenes relating to the cult of Cybele and Attis; of the rectangular *lanx* ("dish") recovered from the river Tyne and in the duke of Northumberland's collection, which depicts Apollo, Artemis, Leto, Athena, etc., on the island of Delos, where Julian the Apostate sacrificed in 363; of the *missorium*

("circular dish") at Madrid, portraying Theodosius enthroned in the midst of his court; and of the silver-gilt *missorium* discovered at Cesena, Italy, the central medallion of which shows a group of persons picnicking *al fresco*, above, and a groom leading out a horse from its stable, below. Of the late hoards, four are in the British museum. These are the Esquiline treasure, which includes the bridal casket presented to a Christian lady, Proiecta, on the occasion of her marriage to Secundinus, and four statuettes of city-personifications; the Carthage treasure, partly Christian; the cache of pieces from Coleraine, Ireland; and the Mildenhall treasure from Suffolk, also containing some Christian objects, but of which the most outstanding items are pagan—the great Oceanus dish, nearly two feet in diameter, and the two smaller dishes with Bacchic figures, completely classical in style and virtually free from the late-antique designer's usual defects of draftsmanship. The hoard from Traprain Law, Scotland, comprising both pagan and Christian pieces, is in the National Museum of Antiquities, Edinburgh. Where precisely the Roman silversmiths' workshops were located is not known, but the great Mediterranean cities—Rome, Alexandria, Antioch and Ephesus—and also some of the leading Gaulish cities were certainly centres of this art and the master craftsmen often traveled in the service of their patrons.

Of the goldsmith's art one example only can be cited—the *patera* from Rennes (in the Cabinet des Médailles, Paris). The central scene is the drinking contest between Hercules and Bacchus, encircled by a frieze containing a Bacchic procession; the outer zone of decoration consists of 16 inset *aurei*, of which the obverse portraits of emperors and empresses from Hadrian to Caracalla are exposed to view and date it in the early 3rd century.

Decorated bronze objects of the Roman age include vessels of various types, mounts for chariots, horse harness and domestic furniture and also brooches, which in the northwestern areas of the empire were often inlaid with polychrome enamel. Of particular interest are the pieces of decorated bronze armour used by gladiators, legionaries on parade and, above all, the auxiliary horsemen of the Roman army when taking part in the sports or tournaments described by the Hadrianic writer Arrian. Examples of the face-mask-visor helmets worn by horsemen on those occasions are especially impressive and have come to light in many regions of the empire, notably in Britain, Germany, the Danubian countries and northern Syria. Remarkable finds were made at Straubing, Bavaria, in 1950.

2. Ivories and Wood Carving.—Ivory was a popular material for minor sculpture. It was worked in the round and in relief and in such forms as small portraits, figurines, caskets, such as that at Brescia (5th-century) and furniture ornaments, of which the carved plaques composing the "Cathedra of Maximianus" at Ravenna (probably 5th-century) provide a notable instance. The consular and other diptychs (*see* DIPTYCH) are one of the most distinctive types of ivory relief work in the 4th and 5th centuries. Among them are such masterpieces that kept alive the traditions of Hellenistic carving as the diptych of the Symmachi and Nicomachi (of which one leaf is in the Victoria and Albert museum, London, the other in the Cluny museum, Paris) and some outstandingly fine examples of late antique portraiture, for instance, the Probus diptych at Aosta with the double portrait of Honorius, the Felix diptych in Paris (dated 428) and that of Boethius, consul in 487, at Brescia. Of wood carving one example must suffice—the panels with Biblical scenes on the 5th-century door of the church of Sta. Sabina on the Aventine.

3. Gems, Cameos, etc.—Many types of carving in precious stones were practised by Roman-age craftsmen, and it is to them that the credit goes for the majority of the *intaglios* which have survived from ancient times. The widespread taste for *intaglios* is witnessed to by the large numbers of existing glass-paste imitations reproducing their subjects, which include portraits of both imperial and private persons, and a large variety of divine and mythological groups and figures, personifications, animals, etc. Many bear the signatures of Greek artists. But the most impressive series of Roman gems consists of the great cameos, cut in different stones and representing imperial persons. Among the earliest of these pieces are the Blacas cameo of onyx in the British museum, portraying Augustus in the guise of Jupiter with aegis; the Gemma Augustea, a sardonyx in Vienna and the Grand Camée de France, a sardonyx in the Bibliothèque Nationale, which were probably carved under Gaius and respectively present the apotheosis of Augustus and of Tiberius, the latter with Divus Augustus also; and the sardonyx cameo of Claudius with Jupiter's aegis in the royal collection at Windsor castle. Late antique examples of the craft are the rectangular sardonyx in the city library at Trier, portraying Constantine I and members of his house, and the onyx in the Rothschild collection in Paris with busts of Honorius and Maria.

Other varieties of carving in precious stones are represented by the miniature head of a girl in the British museum, wearing the hair style of Messallina and Agrippina II, which is cut in *plasma* (root-of-emerald); the onyx vase at Brunswick, possibly of the 1st century, depicting an emperor and empress, as Triptolemus and Demeter; and the late antique Rubens vase in the Walters Art gallery, Baltimore, carved in honey-coloured agate and decorated on the front and back with a naturalistic vine and with the head of a Pan, cupped in acanthus, on either shoulder.

4. Figured Glass.—Closely akin to cameos and vessels cut in precious stones are their substitutes in opaque "cameo glass," worked in two layers, with the designs standing out in white against a dark-blue or bright-blue background. To this class belong the Blue vase from Pompeii (in the Naples museum), with vintaging Cupids; the Auldjo vase (in the British museum) with an exquisitely naturalistic vine; and the celebrated Portland vase, also in the British museum, the scenes on which, recently interpreted as the dream of Atia, mother of Augustus, more probably depict myths relating to the afterlife. Similar imitations of carving in precious stones are the late antique *diatreta* ("cage cups"), the decoration of which is cut back from the outer surface of the mold-cast blank. This "openwork" ornamentation sometimes represents the crisscross meshes of a net, while on other vessels it consists of an elaborate figure scene, the design in either case being very deeply undercut and, for the most part, only connected with the background by short shanks of glass. Of the figured examples the most spectacular surviving specimens are the dark-blue *situla* with a hunting scene in the treasury of St. Mark's, Venice, and the dull-green cup presenting the story of Lycurgus (the Rothschild vase in the British museum). Of the other types of glass with figured decoration, the molded cups with gladiatorial and circus scenes are characteristic of the early imperial period, while the 4th-century glass-worker's craft is represented by vessels with cut or incised designs, the subjects of which are chariot races, hunting and Bacchic scenes and, in the case of the Christian pieces, episodes from the Old and New Testaments. Among the most important centres of glass production under the empire were Syria, Alexandria and the Cologne region.

5. Figured Pottery.—The figured terra-cotta tablewares (*terra sigillata*—a term often incorrectly stretched to cover plain wares) were cheaper versions of the costly decorated silverwares. During the last century of the republic and in the early decades of the 1st century of the empire, Arretium (Arezzo) was the most flourishing centre of the manufacture of a fine type of red-gloss pottery. As the signatures on the pots reveal, the Italian firms often employed Greek and oriental craftsmen, and the mythological and floral themes of the vessels' molded ornamentation owe much to the inspiration of Hellenistic art. From shortly before the middle of the 1st century A.D. onward, the markets enjoyed by the Italian fabrics were captured by the products of potteries now established in southern, central and eastern Gaul. These manufactured cheaper, more mass-produced and aesthetically inferior red-gloss and black-gloss wares, popularly known as "Samian," some varieties of which continued into the 4th century. The decoration of the Gaulish pots was, for the most part, molded; but some vessels carry applied motifs made in individual molds; while others show designs incised to counterfeit cut glass. Yet another type of ornament was carried out in the *en barbotine* technique, by which relief work was produced by trailing liquid clay across the surface of the pot. As regards the content of the decoration, themes from daily life were added to the traditional subjects based on Greco-Roman mythology and on natural history; and it is the *en bar-*

botine hunt cups, of which the leading centre of production was at Castor, Northamptonshire, that are the highlight of the native Romano-British potter's craft. A late-antique class of red-gloss pottery, known as late A ware, with scenes in relief from Greek mythology and from the Roman spectacles and shows, was manufactured in some southern Mediterranean area, probably in Egypt.

6. Coins and Medallions.—Last, a brief allusion must be made to the die-sinker's art, closely linked with that of the gem engraver. The imperial portraits displayed on coins throughout the period of the empire, and on medallions from the early 2nd century onward, provide a continuous iconographic series that can rank with the best works of the portrait sculptors. Many of the reverse designs, beginning with those of the late republic, show figure scenes and single figures treated with the utmost delicacy and finish. Especially noteworthy for their pictorial character are the reverse types of the large 2nd-century bronze medallions, with themes from Greek mythology, Roman legend and contemporary Roman history. The reverse designs of some of the late 3rd- and 4th-century gold and silver presentation pieces illustrate most conspicuously the high standards of craftsmanship to which the late antique could still attain. For interest of content few medallions can rival the large gold multiple, found at Arras, which Constantius Chlorus struck in 296 to commemorate his entry into London after defeating the usurping "British emperor" Carausius. *See* also references under "Roman Art" in the Index.

ROMAN CATHOLIC CHURCH. The word *ecclesia* appears in the New Testament 106 times: twice in its ordinary Greek sense of the assembly of the city-state of Ephesus, once of the community of the Israelites at Sinai, and on all other occasions of the society or Church of Christ, whose members were first called Christians at Antioch. St. Paul uses the word both of local societies, "churches" of Judaea, Asia, Galatia, Macedonia, the Thessalonians or in Philemon's house (as he speaks of "them of Laodicea"), and also of the "whole Church of God." In Matt. 16:18, Christ answers St. Peter's confession, "thou art Christ, the Son of the living God," by saying, "thou art Peter; and upon this rock I will build my church." In Matt. 18:15–20, he defines what may be called ecclesiastical jurisdiction:

> If thy brother shall offend against thee . . . tell the church. And if he will not hear the church, let him be to thee as the heathen and publican; . . . whatsoever you shall bind upon earth, shall be bound also in heaven: and whatsoever you shall loose upon earth, shall be loosed also in heaven. Again I say to you, that if two of you shall consent upon earth, concerning anything whatsoever they shall ask, it shall be done to them by my Father who is in Heaven. For where there are two or three gathered together in my name, there am I in the midst of them.

In tracing the origin of the church back to the apostles, Roman Catholic theologians also cite as the most mature and conscious definition of the apostolic church the following passage in the Epistles to the Ephesians and Colossians: ". . . the Kingdom of the Son of his love, in whom we have redemption through his blood, the remission of sins; Who is the image of the invisible God, the firstborn of every creature: For in him were all things created in heaven and on earth . . . all things were created by him and in him. And he is before all, and by him all things endure. And he is the head of the body, the church" (Col. 1:13–18). "To re-establish all things in Christ . . . and he hath subjected all things under his feet, and hath made him head over all the church, which is his body, and the fulness of him who fills all in all" (Eph. 1:10, 22–23).

This organic unity of Christ, "the fullness of the godhead bodily," with the church "which is his body" is the essence of Catholic ecclesiology. In Christ, according to Roman Catholic doctrine, the godhead assumed human nature: the nature of man is united in Christ with the nature of God, and the church is therefore the divine organism. But the nature of man implies a historical and instituted existence on earth. "By the very fact of being a body," said Leo XIII, "the church is visible." Its existence, institution, and operation are therefore sacramental. It is

the mystery of the incarnate godhead perpetually realized and available in all time and for all the purpose of the divine incarnation. There can be but one such church and, as it is historical and instituted on earth, there can be but one church visible on earth.

As it is divine as well as human, it contains and consummates the whole divine creation, "the church triumphant, the church suffering and the church militant, and is the fullness [*pleroma*] of him that filleth all in all." Hence it is holy and catholic. Its institution is simultaneously divine and human.

Historically and therefore upon the authority of its divine founder, Roman Catholic theologians assert, this church is the church of his apostles. It is apostolic and its apostolicity is its perpetual attribute. Within the compass of its sacramental purpose it is infallible, in the sphere of faith (*i.e.*, man's apprehension of God) and in the sphere of morals (*i.e.*, man's essential relation with God and man).

This infallible authority, Catholic theologians point out, is not to be confounded in any sense with "power": it is the infallible authority of knowledge which is of the essence of the union of man with God—knowledge not achieved as in the natural sciences externally by observation, hypothesis and experiment, but inherent and essential as God knows himself and his creatures and the nature of the unity which he wills and accomplishes. The effectual operation of this entire sacrament, the vital activity of the divine organism, is known as grace.

Grace (*q.v.*) is the universal operation of the church. It is the initiation, process, and fulfillment of the divine activity of redemption by which God unites his creatures organically with himself and endows them thus with his own vitality. This universal grace or sacrament is effectually realized and defined in seven sacraments, acts of God in and through the divine organism by which the divine life is bestowed and the organic union is accomplished and sustained (*see* SACRAMENT). In the Eucharist (*q.v.*) "under the appearances of bread and wine, Jesus Christ Himself is contained, offered and received." It is the whole act of redemption, the sacrifice—that is, the making holy—of the whole universe in the person of Christ,

> the most divine gift emanating from the depth of the heart of the Redeemer "with desire desiring" this wonderful union with men which was especially designed to spread everywhere the life-giving fruit of His redemptive work (Leo XIII, encyclical *Mirae caritatis*, 1902).

Baptism is the initial reception of the human being into the body of Christ. Confirmation given to members of an age to recognize and will their membership is the sacrament of moral maturity. Marriage is the sacrament which sustains in Christ human generation and family life. Penance restores the union with God when it has been injured or broken by sin. Holy Order creates and sustains the whole institution of priesthood and episcopacy by which the divine organism lives and functions on earth. Thus the penitent confesses his sin to Christ, who hears, judges, and absolves him by means of the human priest, and the sacrifice of Calvary is contemporary with all times as the same sacrifice is offered by the same High Priest employing successive generations of men ordained by Christ for that purpose. The passage or expectation of death is sanctified by the sacrament of extreme unction.

Thus the whole earthly life of every human being is organized in the body of Christ, and the whole organization of the church exists to realize that divine-human community. The history of the church cannot be understood unless its nature and function as the divine-human organism, wholly divine and wholly human and indissolubly one, is first recognized.

St. Luke ends his account of St. Paul's apostolate at Rome with the words "this salvation of God is sent to the Gentiles" (Acts 28:28). St. Paul himself explains the significance of that climax in the Epistle to the Galatians. As a Jew turning to the gentiles he must claim that the old dispensation has been superseded and that to be "in Christ" (a phrase repeated six times in this epistle and constantly used thereafter by St. Paul) is to belong to "the Jerusalem that is above" in which "there can be neither Jew nor Greek."

It was only by the act of God that the sanctities and exclusions of the old law could be at once fulfilled and superseded, and hence the same authority which united Jew and gentile realized the purpose of history. "And if you be Christ's, then are you the seed of Abraham, heirs according to the promise" (Gal. 3:29). In the Epistle to the Ephesians, written probably from Rome, this doctrine of divine consummation becomes explicit, "the dispensation of the fulness [*pleroma*] of times, to re-establish all things in Christ. . . . For he is our peace, who hath made both one, and breaking down the middle wall of partition . . . that he might make the two in himself into one new man, making peace, and might reconcile both to God in one body by the cross. . . . Now therefore you are no more strangers and foreigners; but you are fellow-citizens with the saints, and the domestics of God. Built upon the foundation of the apostles and prophets, Jesus Christ himself being the chief corner stone: In whom all the building, being framed together, groweth up into an holy temple in the Lord."

(T. S. GY.)

IV. The Life of the Church in the 20th Century

I. ORGANIZATION

In Roman Catholic theology the organization of the church—what might be called its constitutional law, or its juridical constitution—is partly of divine institution, partly of its own disposition. That is to say, some elements were established by Christ himself, and others the church, once constituted as a visible, complete human society, has added by its own law. The first, in Catholic doctrine, cannot be changed; they are derived not from principles of political philosophy but from revelation and are taught by the church rather than enacted by it. Indeed, it is not always expressly stated in the law, nor always a matter of theological agreement, whether a particular principle is to be ascribed to divine or ecclesiastical determination. The exposition of this question is presented below under two main divisions: basic constitutional principles, and the actual distribution of functions in the church.

A. Basic Principles

Five principles of ecclesiastical organization may be regarded as basic: (1) the threefold function or power of the priestly office of the church and of its ministers; (2) the establishment of a distinct order, the clergy, as the subject of ministerial and jurisdictional authority; (3) the hierarchical disposition of this order; (4) the hierarchical mode of conferring authority in the church; (5) the active participation of all members of the church in the realization of its total mission in the world.

1. Function of the Church.—In discussing the organization of the church, it is not possible simply to equate organization and government. Catholic doctrine asserts that the church was instituted by Christ as a visible society in which, and through the instrumentality of which, men are to be united to him and through him receive redemption and sanctification. It follows that the church has the same mission and hence the same authority as Christ himself, the office of sanctification, of teaching, and of ruling, corresponding to his threefold title of priest, prophet, and king. In the church these are referred to as the powers of *orders* and of *jurisdiction* (the latter including the function of teaching as well as of legislation, judgment, and administration). But this division is concerned only with the immediate object of ecclesiastical activity. All the church's teaching and all its lawmaking are ordained toward the single end of sanctification and salvation of souls, and apart from it would have no meaning or finality. Hence the "organization" of the Roman Catholic Church necessarily includes the method of disposition of its cult, doctrine, and discipline, partly because they are inseparably related in purpose and in operation, partly because the three powers are commonly united in the same subject of authority.

2. The Clergy.—The threefold function of the priestly office, according to Catholic doctrine, resides in a distinct order, the clergy. The Code of Canon Law states: "Though not all forms of the clergy are divinely instituted, it is of divine establishment that there be in the Church a *clergy* distinct from the *laity* . . ." (can. 107); and "It is the institution of orders which, by establishment of Christ, distinguishes the clergy from the laity with a view to the government of the faithful and the ministry of divine worship" (can. 948). The significance of this is that as Christ chose to apply the fruits of redemption through the instrumentality of a society, the church, so he determined also that in this society the function of teaching, directing, and sanctifying in his name and person was to be vested in a distinct group, exclusively dedicated to the service of God and the sanctification of men, in the manner of the priestly and Levitical orders of the Old Testament.

The constitution of a distinct order to fill the office of ministry and government in the church does not imply that the clergy are a superior class (or caste) and the laity inferior, or that membership in the church is more complete or more perfect in the clergy than in the laity. The right of teaching, directing, and sanctifying the community is exercised by the clergy not in their own name or authority but in the name and place of Christ. By themselves and in themselves the clergy are also of the faithful.

3. Hierarchy.—The powers of orders and jurisdiction are conferred not indivisibly but in various degrees or grades, referred to as the hierarchical (*hiera*, "sacred"; *arche*, "rule") constitution of the clergy. Since both the power of orders and the power of jurisdiction exist in hierarchical form, however, a further distinction is necessary. From the point of view of orders, it is, according to Catholic doctrine, of divine institution that there be bishops, priests, and other ministers, including at least the diaconate; the further distribution of ministerial functions in the offices of subdeacon and the minor orders is attributed to ecclesiastical institution. From the point of view of jurisdiction, it is, according to Catholic theology, of divine institution that there be a supreme pontiff and an episcopate; the exercise of jurisdiction by the Roman curia, by vicars and prefects apostolic, by pastors, and by certain institutes of religious is of ecclesiastical origin.

4. Conferring Authority.—The constitution of the church is hierarchical not only in the derived sense (that the powers of ministry and government exist in unequal grades) but also in the original sense that these powers come down, in a special way, from God, rather than up, as it were, from the people. Unlike civil society, in the church neither the power of orders nor of jurisdiction ever resides in the faithful as a whole, to be conferred by them on certain subjects.

The power of orders is received by ordination (*see* Holy Orders; Ordination). From the original meaning, of a disposition of things according to some norm, the term "order" has come to signify the rights and powers so disposed and also the rank or state of those possessing them. A man is constituted in the different grades of the hierarchy of orders by a rite signifying incorporation into a state in which a certain participation of the priestly office is enjoyed.

In jurisdiction, a distinction is made between the supreme pontificate and other grades of authority. The pope's jurisdiction is received immediately from God, upon his election and acceptance. Hence in the election of a pope the electors do not confer jurisdiction, they merely supply the condition of selecting a person. But the mode of selecting him is not determined by divine law; the form of papal election is a matter of canon law, and it has changed from time to time (*see* Conclave). Since the electors do not confer the authority, neither can they revoke it, or limit it, or determine it, or require that consent be obtained for its exercise.

In every other grade besides the pope's, jurisdiction is dependent upon what is called a "canonical mission," the assignment of some jurisdictional function together with the designation of the subjects in whose regard it is to be exercised. Episcopal consecration itself is considered to confer the total priesthood, with the title of authority both of orders and of government in the church; but the use of the latter is dependent upon a further act of the Roman pontiff. This may be the assignment of a specified territory or diocese. Or the canonical mission may consist in the convocation of the whole episcopal college to deliberate in general council upon certain specified matters of doctrine or discipline. In this way the legal principle of the dependence of all nonpapal jurisdiction upon a canonical mission is compatible with the thesis

that episcopal jurisdiction itself is conferred by divine right in the act of episcopal consecration.

Since the mode of providing the canonical mission is a matter of ecclesiastical law, it has varied in the course of history. In earlier times the bishop was always consecrated for a particular see, with the consent of the bishops of the province and of the metropolitan, communion with Rome being supposed; thus the canonical mission was inseparable from consecration and the distinction between the bishop's powers of orders and of jurisdiction did not arise.

5. The Laity.—As stated above, the organization of the Roman Catholic Church cannot be equated with the forms and modes of its government. The laity, who do not participate directly in the government of the church, are as truly component of the people of God as are the clergy; in addition, they are not merely subjects but have their own active role in the prosecution of the church's total mission, the salvation and sanctification of the world. The detailed exposition of this activity pertains more to the next section, *Division of Functions*.

B. Division of Functions

Authority in the church resides in the Roman pontiff, in the bishops, and in other grades of ecclesiastical institution. Some grades of the hierarchy have authority with respect to the whole church, others with respect to a part of it, the basis of the division being a title either of territorial nature, or of juridical rite, or of religious profession.

1. The Roman Pontiff.—It was defined by the first Vatican Council, and is stated in the Code of Canon Law, that the pope has full and supreme authority over the whole church, both in teaching matters of faith and morals and in enacting matters of discipline and government (*see* Pope).

In designating the acts of the pope the older terms "bull" and "brief" (*see* Diplomatic: *Papal Chancery*), which refer to the external form of documents, are less significant than the terms which indicate something of their internal content. Many forms are used, principally the apostolic constitution, the encyclical, the *motu proprio*, and the allocution. (*a*) The apostolic constitution is a very solemn document that may contain a dogmatic definition, the establishment of a new diocese, the enactment of a new law, etc. (*b*) The encyclical is the form most commonly employed for magisterial or pastoral matters: to teach moral principles (social action, Christian marriage, education, etc.), to elaborate matters of dogma (on the Mystical Body, the priesthood, the Sacred Heart, biblical studies, the liturgy, virginity, precarious trends in philosophy and theology), or to request prayers for the missions, the persecuted, or some similar cause of general concern. (*c*) The *motu proprio* is usually juridical, containing either new law or an abrogation of old law, or a dispensation from a law, etc. Technically the words signify that the enactment proceeds from the pope's own initiative; in practice they indicate that, whatever its origin, the pope takes a special interest in the provision and wishes to emphasize his personal sponsorship of it. (*d*) At one time allocutions were formal addresses delivered by the pope to select groups of cardinals on the occasion of consistories. Under later popes allocutions given not only to groups of cardinals or bishops but also to audiences of the laity—congresses of doctors, scientists, educators, nurses, labour unions, groups of youth organizations, etc.—became a vehicle for the exercise of the ordinary teaching authority of the pope and gave rise to many important declarations in matters of medical, conjugal, and social morality.

2. The Episcopal College.—Properly speaking, the episcopal college, as a subject of supreme authority over the universal church, is not adequately distinct from the Roman pontiff. The pope is a member of the college, and its head. Thus the plenitude of authority in the church resides in the episcopal college, under and with the pope, the bishop of Rome. The total college of bishops is conceived as the continuation of the total apostolic college, with the pope as successor to Peter and the other bishops as successors to the other apostles. By episcopal consecration the bishop becomes a member of the college with a responsibility and authority toward the whole church, not merely toward his own particular flock (*see* above, *Conferring Authority*).

One form in which the episcopal college as a whole has functioned from ancient times is the ecumenical council (*see* Council). It is the traditional teaching that the council has full and supreme authority in the church, including the power both of teaching and of government. As a subject of supreme authority, however, the council is not adequately distinct from the pope. He is a member of the council, indeed its head, in such wise that its existence and activity depend upon his convoking it, determining the agenda, presiding, and confirming its acts. Yet the acts of the council are the acts of the whole college of bishops; they are not the acts of the pope alone, with the other bishops merely advising. The pope, on the other hand, has by himself the same supreme authority as the college of bishops. While he does not act in affairs of greater moment without attention to the judgment of the bishops throughout the world, there are no matters reserved to a council which the pope himself has not the authority to decide or to enact.

Another form of implementation of the principle of collegiality is found in the Synod of Bishops established by Pope Paul VI, Sept. 14, 1965. Although the institution itself is permanent, it is not continuously active, but only when convoked in "general," "extraordinary," or "special" sessions, together with the pope, to provide information and counsel, and in particular cases to make deliberative decisions, upon matters of doctrine or discipline proposed in advance. To a large extent the membership of the sessions is determined by the election of representatives from the various national conferences of bishops throughout the world, on a scale proportionate to the membership of the conferences.

To a lesser degree the principle of the collegial authority of the bishops is also realized in the councils and conferences of the bishops of a province or nation, in which they exercise their providence not over their own special flock alone but over that larger portion of the church which they collectively govern (*see* below, *Local Councils and Conferences*).

3. The Roman Curia.—The pope is aided by a staff of cardinals, the Roman Curia ("court"), which acts as the judicial and executive organs of the papal office. The pontiff and the Curia together comprise the "Holy See" or "Apostolic See"; the term "see" (*sedes*), which originally signified a chair (a "seat" of authority; *cf. cathedra*, "throne"), has thus come to designate the authority itself, or the community governed ("see of Rome"), or, as here, the central government. Though the pope does not have sole responsibility for the church, he does have the responsibility for conducting its ordinary government, and the Roman Curia expedites his judicial and executive functions.

From very early times there is evidence of a special staff of advisers to the pope. Obviously the need for such a staff grew as centralization increased. At first the pope depended largely upon the bishops of the suburban sees around Rome (to become the "cardinal bishops") and upon the principal priests and deacons of the city, who were called the "cardinals" (from *cardo*, "hinge" or "turning point") of Rome because of their preeminence. From the 11th century prominent men were called to Rome from other countries and made cardinals, and from the 12th men were appointed cardinals of the Roman church while remaining in their own countries. (*See* also Cardinal.) The cardinals usually met to advise the pope in the form of consistories (*i.e.*, without distinction of departments; *see* Consistory), but in 1588, under Sixtus V, the curial system was established, composed of specialized congregations, tribunals, and offices. This has remained substantially unchanged, with minor modifications by Pius X and the Code of Canon Law.

The Curia Romana is not one body: it is described in the code as comprising 12 congregations, 3 tribunals, and 5 offices (canons 242 ff.).

Offices.—The work of the offices is not so much jurisdictional as secretarial; *i.e.*, they are concerned more with the organization and expedition of activities than with their substance.

Tribunals.—The tribunals exercise judicial jurisdiction: the Sacred Penitentiary in matters of conscience (and usually in secret); the Sacred Roman Rota serving as the Holy See's own court

for causes appealed from local tribunals or submitted to it in the first instance; the Supreme Apostolic Signatura hearing special matters assigned to it by the pope or reviewing questions of procedure arising from cases tried before the Rota.

Congregations.—The great bulk of curial work is done by the congregations: the Congregation for the Doctrine of the Faith (formerly the Holy Office), with responsibility for all matters of faith or morals, and many disciplinary points with which doctrinal matters are closely connected or in which non-Catholics are involved (*e.g.*, mixed marriages); the Congregation of the Consistory, concerned principally with the establishment of dioceses and the appointment of bishops; the Congregation for the Eastern Churches, with authority over all matters involving the members of the Eastern rites individually or collectively; the Congregation of the Propagation of the Faith (*Propaganda Fide*), with similar authority over the affairs of mission territories; the Congregation of the Council (originally created to interpret and execute the decrees of the Council of Trent), concerned with most questions of general ecclesiastical discipline; and the remaining congregations, whose functions are sufficiently described by their respective titles: the Congregations for the Discipline of the Sacraments, of Sacred Rites, of Religious, of Seminaries and Universities, of Ceremonies, of Extraordinary Affairs, and of the Maintenance of St. Peter's.

Only cardinals are members of the congregations, though many other priests, in Rome and throughout the world, are employed as consultors. Though every cardinal is assigned to a number of congregations, the ordinary day-to-day business is necessarily conducted by those who are resident in Rome. Each congregation is headed by a prefect, usually a cardinal; but this position is held by the pope himself in the first three mentioned above, in which a proprefect assumes the ordinary responsibilities of chairmanship.

The Curia is not a legislative body; its functions are executive and judicial. Moreover, even as the executive agents of the pope, the congregations can do little independently of him. Before undertaking any extraordinary project, approval of the pope is required; and all but the most ordinary business, or that for which special faculties have been given, must have his subsequent confirmation, in either common form or specific form. Confirmation in common form does not change the juridic nature of the act; it remains an act of the congregation. Approval in specific form, however, makes the act an act of the pope himself and attributes to it (if the nature of the matter permits) the force of pontifical law.

The juridical acts of the congregations are principally of the following nature: decrees or instructions regarding the mode of observance of the laws; dispensations, permissions, or faculties relating to their relaxation or implementation; the examination and confirmation of the acts of particular councils or of religious institutes (*see* below, *Local Councils and Conferences, States of Perfection*); and interpretation of the laws in response to questions proposed by the bishops or other members of the church. By reason of its special competence in matters of faith and morals, the Congregation for the Doctrine of the Faith also imparts guidance and directives pertaining to the magisterial order.

4. Local Ordinaries.—The pope and the episcopal college have authority over the whole church. But the Code of Canon Law states: "The bishops are the successors of the Apostles, and by divine disposition they are placed in charge of particular churches which they govern with ordinary power under the authority of the Roman Pontiff" (can. 329). Although the bishop of a diocese is the most familiar territorial head, the territorial divisions are more varied in nature and juridical constitution than this would suggest. In terms of the hierarchy not of orders but of jurisdiction, the expression "local ordinary" designates a certain level of governing authority, whether the superior of the territory is the bishop of a diocese or the vicar of a vicariate apostolic in mission countries, or the prelate or abbot in charge of a prelature or abbacy *nullius* (distinct from any diocese). The same term is applied to a vicar general, who enjoys practically the same jurisdiction as the proper superior, and to the person temporarily in charge of a territory because of the incumbent's incapacity, demise, or transfer.

The authority of the local ordinary, like that of the church itself and of the pope and episcopal college, includes both teaching and government. Of the authority to teach in matters of faith and morals, the Code of Canon Law states: "Although the bishops are not endowed with infallibility in their teaching when acting individually or even when gathered in particular councils, yet they are, under the authority of the Roman Pontiff, truly teachers and masters with respect to the faithful committed to their care." Of the bishops' authority to govern in matters of discipline, the code states: "They have the right and duty to govern their diocese, in spiritual matters and in temporal, with legislative, judicial, and coactive power, to be exercised according to the norms of the sacred canons" (can. 335, sec. 1); this principle is extended to other local ordinaries in other canons. Judicial jurisdiction is exercised by the tribunal which should be established in every ecclesiastical territory, with the *officialis* usually taking the ordinary's place as judge. Executive jurisdiction is exercised in various administrative or coactive acts, as the issuing of dispensations, regulations, or penalties. Legislative jurisdiction is exercised in the enactment of diocesan statutes or in the issuance of precepts applying to some temporary or local need.

The ordinary, of course, cannot enact contrarily to the laws of the universal church, permitting what it prohibits or prohibiting what it positively permits. In certain specified matters his power is further restricted by the necessity to obtain the consent of the cathedral chapter (where this institution exists; *see* CATHEDRAL) or of the diocesan consultors; but for the most part his dependence upon his advisers is limited to consultation. In the exercise of his legislative function he may act with representative members of his clergy and laity, sometimes in a diocesan synod (which should be held at stated intervals); but even in the synodal procedure the ordinary himself is the sole legislator. It was urged by the second Vatican Council (1965) that an advisory pastoral council be established in each diocese, with the participation of chosen clergy, religious, and laity.

The diocese is divided into parishes, presided over by pastors. It is normally upon the pastor and his assistants that the faithful depend for the ordinary ministrations of the Holy Sacrifice, the sacraments, the preaching of the Word of God, catechetical instruction, blessings, and other sacramentals. The pastor's jurisdiction is concerned chiefly with the personal spiritual welfare of the individual rather than with affairs in the public interest, though in certain emergency situations he is empowered to act in matters usually reserved to the local ordinary.

5. Local Councils and Conferences.—Besides the division into dioceses or analogous territories, each under its local ordinary, groups of such territories are formed into ecclesiastical provinces, corresponding so far as feasible with political divisions. The ordinary of the principal see is called the "metropolitan," the other bishops or ordinaries his "suffragans." The metropolitan is not juridically superior to his suffragans and does not have ordinary jurisdiction over them or over the province as a whole, though he is given by the law certain rights of vigilance and of extraordinarily supplying for deficiencies in their administration. (*See* also METROPOLITAN.) The patriarchs of the Eastern churches are not comparable to the Latin metropolitans; they do have direct and ordinary jurisdiction over the whole territory of the patriarchate and over the bishops and metropolitans of its subordinate divisions. Although the metropolitan is, ideally, an archbishop with an archdiocese, the title of archbishop is sometimes conferred as a personal distinction, and the rank of archdiocese may attach to a territory which is not the principal see of a province. Periodically all the ordinaries of a province should be assembled in the form of a provincial council under the presidency of the metropolitan.

Periodically, too, though at no specified intervals, the ordinaries of all the provinces of a nation or comparable area may gather in what is called plenary council (as the three plenary councils held at Baltimore for the whole of the United States in

1852, 1866, and 1884). For these the consent of the Holy See is required, and the latter is represented by a legate who convokes the council and presides. The acts of a plenary council must be confirmed by the Holy See. Unlike the diocesan synod, where the bishop is the sole legislator, the plenary and provincial councils are themselves legislative bodies. Their laws are valid for the whole territory involved, and the ordinaries can dispense only for a just cause and in particular cases.

Similar to the local councils, but on a less solemn scale and more adapted to the managing of contemporary and changing situations, are the episcopal conferences, composed of all the bishops of a country and commonly held annually. These were given official canonical status by decree of the second Vatican Council in 1965. For the most part the function of the conferences is consultative; *i.e.*, their resolutions, etc., do not have binding force unless they are accepted and enacted by the individual local ordinaries. In specific matters, however, determined by law or particular mandate of the pope, their decisions have the force of law throughout the territory, if they are enacted by a two-thirds majority and confirmed by the Holy See. The elected chairman of each conference is an *ex officio* member of the "extraordinary" and "special" sessions of the Synod of Bishops of the universal church.

6. Distinction of Rites.—The principles outlined above are valid both for the church of the West and for that of the East, though the terminology employed (*e.g.*, "ordinary" rather than "hierarch") is that of Western law and tradition. There is, however, another division, on the bases of liturgy and discipline, not only of a territorial nature but of jurisdiction itself, between the Eastern churches or rites in communion with Rome (*see* below, *The Catholic Eastern Rites*) and the Western or Latin rite. The primal basis of the distinction of Eastern and Western churches was the division of the Roman Empire into eastern and western parts under Diocletian in the 3rd century. In the 10th century and following, all of the Eastern churches were separated from Rome at one time or another; in the process of reunion (on the part of those that were reunited) they were reestablished hierarchically, retaining, however, their own liturgy and the discipline they had carried on from earlier times or had established by provincial synods. In 1949, however, a unified code of law for all the Uniate Eastern churches began to appear, being promulgated as the separate sections were completed. (*See* CANON LAW: *Eastern Churches.*)

In general the organization of the Eastern churches, in its larger outlines, is the same as that of the Latin rite, except for the jurisdiction of the patriarchs. But whereas the territorial division of dioceses, etc., in the Latin rite is exclusive, in the sense that only one ordinary has jurisdiction over a territory, the jurisdiction of the Eastern hierarchs may be cumulative; *i.e.*, within the same general territory more than one superior may have jurisdiction, with respect to the subjects of his own rite. Outside the territories of the patriarchates, the faithful of the Eastern rites are generally served by the Latin clergy; though in some areas, where they are more numerous, they may have their own clergy and churches and even their own hierarchy. Conversely, in regions predominantly Oriental the faithful of the Latin rite are generally served by the Eastern clergy and hierarchy. But even under the ministry of the clergy of another rite, the faithful retain their own proper rite and, so far as possible, its own specific discipline.

The principle for determining the rite to which a Catholic belongs is that a person is ascribed to that rite in the ceremonies of which he is baptized. In the case of children, this should be the rite of the parents, or of the father (if the parents are of mixed rite), or of the Catholic parent (if they are of mixed religion). Once ascribed legitimately to one rite, a person cannot change to another by his own volition or by the sole fact of following the liturgy and practice of the other for any length of time, but solely by indult from the Holy See. This is not readily given, as it is desirable to maintain the integrity and vitality of the various rites. Converts, however, are allowed to choose the rite they prefer; a wife may, at her own choice, change to her husband's rite at the time of marriage or later; and children under the legal age of puberty are automatically transferred if a change of rite is legitimately obtained by their parents or, in a case of mixed rite, by their father.

7. States of Perfection.—From very early times there has existed a special state, canonically recognized and regulated, composed of those who dedicate themselves to the pursuit of Christian perfection through the exercise of the evangelical "counsels" of poverty, chastity, and obedience, to which they bind themselves by public profession of vows. The canonical development of the state of perfection has seen many variations; but at least from the 6th century it was considered to include two essential elements: living in community and professing the three public vows (*see* MONASTICISM; VOW).

From the 17th century in fact, and since 1918 in the law itself, similar recognition has been extended to the "societies of common life," which, while living in common, do not make profession of the three counsels in the form of public vows accepted by the church. As of 1947, moreover, by enactment of Pius XII, "secular institutes," composed of clerics or lay people who bind themselves to the three evangelical counsels but do not live in common, have also acquired the dignity of a canonical state of perfection (*see* SECULAR INSTITUTE).

Members of these organizations are said to be in a state of perfection not in the sense that they have achieved perfection or possess it in a greater degree than others but simply because they have adopted a way of life that is conducive to the pursuit of perfection and have bound themselves to strive for their own sanctification and that of the world.

Each of these societies has the authority necessary for the direction of its members toward the ends, personal and collective, of the institute. For various reasons, especially the supraterritorial character of the larger institutes, it has been the practice, since at least the 11th century, to confer upon clerical orders a power of jurisdiction comparable to that of the local ordinaries, for the government of their own internal affairs and specific ministries; they are to this extent subject immediately to the Roman pontiff rather than to the ordinary of the territory. The major superiors of these institutes are also entitled ordinaries. This privilege, known as exemption, is limited by many provisions of the law in which the religious are subjected to the jurisdiction of the local ordinary—generally speaking, in all matters concerned with pastoral care.

8. The Laity.—A more satisfying recognition and formulation of the status and function of the laity in the church was one of the principal aims of the second Vatican Council. The church was founded for the purpose of spreading the Kingdom of Christ throughout the earth, to enable all men to share in his saving redemption, and that through them the whole world might enter into a relationship with Christ. All who are incorporated into the church form one body, and every member has a responsibility for the fulfillment of the church's total mission in the world. The laity, therefore, have not only their own personal vocation to sanctity and perfection in their state of life, but also a commission to participate actively in the threefold office of Christ and of the church. They do this by the offering of spiritual sacrifice, by bearing witness in their lives to the values of the gospel message, and by striving for the more perfect realization of Christ's redemptive mission.

The redemptive mission of Christ includes the salvation of men and the renewal of the temporal order. The laity participate in both. They assist the hierarchy in its office by advising ecclesiastical superiors in matters of their special competence, by teaching and catechetical instruction, by aiding in the organization and promotion of concerted efforts toward various religious objectives, etc. But their more specific apostolate is the endeavour to infuse a Christian spirit into the mentality, customs, laws, and structures of the community of men. By their example, by the spoken and written word, and by cooperative activity they are to be the leaven by which the world is permeated with the spirit of the gospel, created goods are perfected and directed more effectively to the ends for which they were made, and the order of truth, justice, love, and freedom is realized on earth.

(J. J. RE.)

C. The Catholic Eastern Rites

In this article, the word "rite" signifies not merely liturgical ceremonies but the whole discipline and organization of particular churches. The Catholic Eastern rites are those which have re-established union (hence Eastern rite Catholics are often called Uniates) or canonical communion with the Roman Apostolic See, and thus with the Roman Catholic Church. In this union they accept the Catholic faith, they keep the seven sacraments, and they recognize the pope of Rome as supreme head of the church. But they retain all other characteristics, such as liturgy, spirituality, sacred art, and especially organization, proper to themselves. (*See* above, *Division of Functions: Distinction of Rites.*) Catholics of Eastern rites are estimated to number about 10,500,000, including around 800,000 in the United States.
